The interest of the Tractatus will doubtless culminate for most students in the mysticism with which it concludes. Pure formalism in logic must mean mysticism in philosophy. "Logic is not a theory but a reflexion of the world." It is transcendent. Logic is language. It is the clear expression of all that is expressible. But when we have said all that is sayable there remains unexpressed, inexpressible, the will, the life, the *that* we live as distinct from the *how* we live. "Of the will we cannot speak." "If good or bad willing changes the world, it can only change the limits of the world, not the facts." Philosophy when it follows the right method and says nothing but what can be said, says nothing which concerns philosophy. Such is the conclusion of this remarkable, thought-provoking book.

There is one serious omission of the editors which at times is embarrassing to the student. Writers are referred to whose special theories the reader is presumed to know, but there are no references to guide him should he wish to consult the originals.

H. WILDON CARR.

Outlines of Astronomy.

General Astronomy. By H. Spencer Jones. Pp. viii + 392 + 24 plates. (London: E. Arnold and Co., 1922.) 21*s.* net.

TO deal in any adequate sense and in an elementary manner with the whole subject of astronomy requires both inclinations and aptitudes which are not altogether common. It is a field in which the greatest success may fairly be claimed for English and American writers. Thus in France, in spite of a genius for scientific romance which serves admirably in an allied and more restricted domain, the pen of Arago has found no conspicuous successor. Similarly in Germany the continued success of "Newcomb-Engelmann" is not merely a tribute to the original American masterpiece, but also betrays a native inability to create a serious rival. In one case we may suspect a natural

impatience in tracing detail over a vast region, in the other a lack of that discriminating power which is needed in order to keep the detail in its due subordinate place. A nice sense of proportion and construction is as necessary as a sufficient technical equipment, and modern specialism is scarcely conducive to the combination of these qualities.

In his preface Mr. Jones alludes to the twin difficulties of inclusion and omission. But an author need not be obsessed by such problems in drawing the outlines of a science for the benefit of the uninstructed. His is the right to choose his own material. A critic may insist on orderly arrangement, coherence, and critical accuracy. He may go further and point out that what purports to be a complete picture falls far short of the intended aim, that essential features are lacking. But the author will do well to anticipate these two lines of criticism in a different spirit. The first is universal, and applies to all books as works of art or science. The second is truly pertinent, and yet may be disregarded by the author. For he must draw the picture as he himself sees it, and not as he imagines others will expect it to be drawn. Let it be incomplete or exaggerated, if that cannot be helped, but let it represent a personal view. In this way there is at least more to be gained than would otherwise be lost. It is only thus that a really fresh and graphic delineation becomes possible, and that is not altogether easy in a field where the predecessors have been many and some of them distinguished. Mr. Jones has successfully maintained his independence, and the result will be recognised as conveying a consistent, complete, and just representation of modern astronomy within the assigned limits of space and technical reasoning. A very simple algebraic or trigonometric formula is introduced occasionally, but the arguments, though generally effective, are elementary, and involve little or no formal mathematics. The book is written in a clear and simple style, and the illustrations have been chosen with judicious care.

The last three decades have witnessed a wonderful transformation in astronomy. To the undiscerning eye the progress of the science during the nineteenth century may well have appeared dull. It was then that the foundations were being laid for future advance, and this on two distinct lines. Steady adherence to established methods was laboriously accumulating the material on which notable generalisations and a more critical view of the whole subject could be founded, and at the same time more enterprising spirits were making trial of new methods which, owing to difficulties of technique, were not always immediately productive. It has so happened that the triumph over these difficulties, with the provision of new and powerful instrumental resources, has coincided with the critical discussion for which the stores of existing observations were ripe. The result of this confluence is that a text-book of general astronomy written in the nineteenth century, however excellent at the date of its appearance, could scarcely be brought up to date by any process short of re-writing the whole of it more or less completely.

It is, however, obvious that the foundations of astronomy have been so well and truly laid that the earlier chapters must follow a long familiar track. The landmarks are old, but even here there is some liberty of choice, and Mr. Jones's choice appears both fresh and judicious. A clear preliminary chapter on the celestial sphere shows that the author intends to be serious and not merely popular. It is not evident why the definitions of the ecliptic and celestial longitude and latitude are deferred to a later chapter. The two chapters which treat of the earth are excellent, the topics being well chosen and discussed at such length as to make them really instructive. The statement (p. 42) that twilight is least at the equinoxes is incorrect; in this country shortest twilight falls some three weeks nearer the winter solstice. In the chapter on the moon, which follows, a clear statement of the principal features of the lunar motion is very welcome.

The treatment of the sun naturally introduces the results of more modern work. It is curious that the word photosphere does not seem to occur, and the subtle problem connected therewith is entirely ignored. The subject of eclipses is explained very lucidly in a separate chapter. Here it may be noted that the index is capable of improvement. Thus the Einstein test by the deviation of stars in the field of the sun is described (p. 155), but omitted from the index, and the same thing happens with Janssen's and Lockyer's discovery (p. 130), that it was possible to observe prominences without an eclipse.

As one would expect from the author, the chapter on astronomical instruments is excellent, dealing with the more important modern types in a lucid manner. Astronomical observations are also explained briefly but clearly. A very attractive account of the planets and their systems is preceded by a simple explanation of the main features of planetary motion, and followed by a descriptive treatment of comets and meteors.

The concluding section of the book consists of three chapters dealing with the stars and the stellar system in the light of modern research. Possibly a fuller discussion of the whole of this fascinating subject would have been welcome, but restraint is necessary in a branch where research is progressing at a particularly rapid rate, and within the limits of space assigned it is difficult to see how a better choice of subject-

matter could have been made. The subject of photometry receives that attention to which its importance entitles it. On the other hand, radial motions are passed over with little mention. The confusion of Betelgeuse (p. 285) with α Bootis is curious, and other slips will be noticed. The spectroscopic determination of the parallax of α Centauri (p. 330) is due to W. H. Wright (not to Campbell). An argument occurring in the section on short-period variables is quite unsound; it would be just as reasonable to assert that the earth-moon system cannot be binary on similar grounds. But in such matters allowance ought to be made for the need for brevity. The subject of these three final chapters might easily be expanded into a large volume.

It cannot be denied that the book is marred by a number of minor errors. They may be attributed to the want of the author's revision, owing to the recent eclipse expedition of which he was in charge. In passing a book through the press the most zealous and competent editor can scarcely replace the author himself. Certain corrections are called for in the interest of accuracy and for the instruction of the serious student, and will be easily introduced in a later edition. In the meantime, the general reader should find in the present work an interesting review of the methods and principal features of modern astronomy, from which he can gain an insight into its spirit and general trend. H. C. P.

A Text-book of Metallography.

An Introduction to the Study of Metallography and Macrography. By Dr. L. Guillet and A. Portevin. Translated by L. Taverner. With an Introduction by Prof. H. C. H. Carpenter. Pp. xvi+289+Plates cxvii. (London: G. Bell and Sons, Ltd., 1922.) 30*s.* net.

THE handsome volume before us is the largest general text-book of metallography that has yet appeared in English, and the preface states that the authors have in preparation a still larger treatise, which is evidently intended to deal with the subject very fully. Their presentation is essentially French, and is worthy of the school founded by Osmond and Le Chatelier. In any historical account of the origins of metallography the name of Sorby is necessarily mentioned, but neither the authors nor Prof. Carpenter, who writes an introduction, quite do justice to his remarkable work. Sorby not only devised the method of preparing and examining micro-sections of metals, but he also described correctly and identified the principal constituents of several varieties of iron and steel, and recorded their structures in photographs which leave nothing to be desired in clearness and accuracy. These photographs appeared in 1887, or seven years before the classical paper of Osmond, in which the study was advanced many stages further. Sorby's experiments were actually made, at least with the lower powers, in 1864, but the lack of interest taken in them by manufacturers led him to put them aside until the work of Martens again directed attention to the use of the microscope in the study of metals.

The characteristic feature of this volume by Messrs. Guillet and Portevin is its wealth of illustrations, mostly excellent. The least satisfactory are those showing the process of recrystallisation in cold-worked metals, for which better material is now available. Taken as a whole, however, the plates reach a very high standard. The equilibrium diagram and other theoretical sections are treated briefly but clearly, and more stress is laid on practical applications than is usual in text-books. The physical properties of alloys are only cursorily reviewed, and the experimental determination of changes of volume might well have been described, in view of the fact that dilatometric results are used freely in the account of the special steels. The chapter on mechanical testing describes French machines, and needs to be supplemented for English readers. No fatigue test is included, and the list of etching reagents (awkwardly called "etchants") is rather meagre, and might well be enlarged. The concrete studies of groups of technical alloys are very useful, and bring together a large amount of information, but the section on alloy steels is out-of-date; it is based on the older papers of Guillet, and the important group of light alloys receives little attention.

The most novel feature of the work is the section devoted to macrography. This is actually older in date than microscopical metallography, having been employed by Widmanstätten in 1808 in the study of meteorites. It is not so well known as it should be that Sorby employed "nature-printing" to record the structure of converted bars in 1864, printing from an etched surface by means of printers' ink. This method was extensively used in this country during the war for examining shell and other forgings. The authors do not describe nature-printing, but give a good account of the etching of metallic surfaces for macro-photography, and of the interpretation of the results so obtained. This section is of great value.

The translation is clear and smooth. Proper names have suffered rather badly (Bénédick for Benedicks, Marten for Martens, Brani for Bruni, Carnilley for Carnelley, etc.) but other misprints do not appear to be numerous. As a comprehensive survey of a subject of growing importance, the book is likely to have a wide popularity. C. H. D.

Our Bookshelf.

Gas Manufacture, Distribution and Use: Teachers' Notes for Lessons, with Blackboard Illustrations. Second and revised edition. Pp. 148. (London: Compiled and Published by the British Commercial Gas Association, 30 Grosvenor Gardens, 1922.)

As may be gathered from the title, the primary purpose of this volume is to place at the disposal of teachers who wish to give lessons on the subject trustworthy information which may be of service to them. In addition, the introduction of a number of simple and clear diagrams is intended to lighten the task of illustrating lessons on the blackboard. The book will serve its purpose admirably. The information is of the right kind, and in the hands of a good teacher, who will naturally select what he wants for his own purpose, should be capable of rendering excellent service.

It would be a mistake, however, to suppose that the usefulness of the book would be confined to those who wish to use it for teaching purposes. As a matter of fact it brings together, and presents systematically, descriptions of gas plants, gas appliances of all kinds, and illustrations of their use such as it would be impossible to consult, so far as we know, in any single work. There is probably nobody in the gas industry, or preparing for it, who would not find this book useful at times, and for the journalist who in the absence of more thrilling themes may be called upon to deal with "the gas peril" it should provide a very desirable substratum of corrective knowledge.

Moreover, the householder who wishes to have a better understanding of the construction and method of operation of the gas appliances which he has installed, or is thinking of installing, will almost always be able to find something pertinent to the questions before him in one or other of the 121 lessons here set out, while in Appendix C, under the head "Gas by the Therm," he will find a clear explanation of this unit of heat as a basis of charge with a summary of the circumstances leading up to the Gas Regulation Act of 1920.

J. W. C.

The Failure of Metals under Internal and Prolonged Stress: a General Discussion held on Wednesday, April 6, 1921, in the Hall of the Institution of Mechanical Engineers. Edited by F. S. Spiers. Pp. iv+215. (London: Faraday Society, 1921.) 10*s.* 6*d.* net.

THE general discussion on the failure of metals, organised by the Faraday Society in conjunction with a number of technical institutions, was one of the most successful of the series. The volume containing the papers and discussions is likely to serve for some time to come as the standard source of information on season-cracking and similar defects in worked metals. The phenomenon is a puzzling one, and it was necessary first of all to collect the observations of many workers, whose experience touched the subject at different points, before any attempt at explanation could be made. The metallurgist and engineer, however wide his experience, will probably find much in the volume that is new to him. The very extensive records from Woolwich Arsenal are particularly valuable.

The theory of the origin of season-cracking is still imperfect. The hypothetical amorphous film between the crystal grains of metals is invoked by Dr. Rosenhain and others as the responsible material, but other workers have found the evidence unconvincing, and it is too early to say that any satisfactory explanation of the whole of the facts has been devised. Hardening cracks in steel present a rather different problem, but one so closely related to that of season-cracking as to justify their inclusion in the same volume. Fortunately, the results of recent work are not of academic interest merely, but experiments have shown that the cracking of cold-worked objects may be prevented entirely by annealing at a temperature so low as to cause no appreciable loss of hardness. This result has great theoretical as well as practical importance.

C. H. D.

Die europäischen Bienen (Apidæ). Das Leben und Wirken unserer Blumenwespen. Bearbeitet von Prof. Dr. H. Friese. 1 Lieferung. Pp. 112+7 Tafeln. (Berlin und Leipzig: W. de Gruyter und Co., 1922.) 10*s.*

THE name of Dr. H. Friese is well known to students of the Hymenoptera, and his published writings on bees render him competent for a work of this description. His aim is to give a general account of the life and habits of European bees within a compass of about 450 pages, of which 112 pp. are comprised in this first instalment. In some ways the work is scarcely abreast of the times, and it is a matter of surprise to find in the introduction the old Linnean classification of insects still adhered to, with the dragonflies included among the Orthoptera. Bees are regarded as constituting a single family, and the other major groups of Hymenoptera are relegated to a similar status. Furthermore, no outline of the classification of the Apidæ is presented to the reader, which is a distinct drawback. The section devoted to the general characters of bees might well have been longer—it is too brief and elementary to be of much value to the serious student. We note only the barest reference to the salivary glands, respiration system and other organs, although several pages are devoted to an account of the body-hairs, nearly fifty different kinds being illustrated. The author's main aim, however, is bionomics, and it is evident that the remainder of the book, when completed, will provide a trustworthy, well-illustrated dissertation on the habits and life-economy of the insects with which it deals. The seven coloured plates which accompany the present part are composed of original figures. Those which portray the various types of nest structure are among the most attractive illustrations of their kind which we have seen.

A. D. IMMS.

Morbid Fears and Compulsions: their Psychology and Psychoanalytic Treatment. By Dr. H. W. Frink. Reprinted from the American Edition. Pp. xxiv+344. (London: Kegan Paul, Trench, Trubner and Co., Ltd., 1921.) 21*s.* net.

DR. FRINK'S text-book deals with psycho-analytical treatment and the theories on which it is based. In the introduction, by the late Dr. James Putnam, there is a criticism of Freud's view that the duty of the psychotherapist ends with the undeception of the patient and the dissipation of his symptoms, without any considera-

tion of the use he will make of his newly acquired freedom.

The first four chapters are devoted to a presentation of the theories underlying psycho-analysis, based on purely Freudian doctrines, but abundantly illustrated by the author's own observations and cases. After a description of sexual development, the unconscious and the censorship, the neuroses are considered in detail—the method of their production, their classification and individual psychology. A long description is given of a case of compulsion neurosis and its analysis, which is of considerable value in illustrating the preceding chapters on theory.

The book is evidently intended for, and will appeal most to, the student who has some acquaintance with psycho-analysis, and is desirous of extending his knowledge on the subject.

Reinforced Concrete Simply Explained. By Dr. Faber. (Oxford Technical Publications.) Pp. 77. (London: H. Frowde and Hodder and Stoughton, 1922.) 5*s.* net.

A VERY clear and simple account of the elementary principles of reinforced concrete design is given in Dr. Faber's book, and it will be found suitable for those who wish to have the knowledge required for the design of simple structures which will be safe, but not necessarily the last word in economy. The book covers the ground required for beams, slabs, and pillars. Both shearing and bending are considered in connexion with beams, and the effects of fixing the ends and of continuity are clearly explained. The design of pillars also includes a simple treatment of the bending moments communicated to the pillar by beams which are integral with it. There are very few blemishes, and these are of a minor character only, *e.g.* on p. 33, Fig. 7, the lower arrow for the dimension *d* is misplaced. On the whole the book is the soundest production of an elementary character which we have yet seen, and will be very useful to students of engineering who have to acquire a knowledge of reinforced concrete among other subjects in their course.

Memoirs of the Geological Survey: England and Wales. The Geology of the London District. (Being the Area included in the Four Sheets of the Special Map of London.) By H. B. Woodward. Second edition, revised, by C. E. N. Bromehead; with Notes on the Palæontology by C. P. Chatwin. Pp. vi+99. (Southampton: Ordnance Survey Office; London: E. Stanford, Ltd., 1922.) 1*s.* 6*d.* net.

THIS new edition of the brief general geological guide to the London District, issued at a moderate price, will be of interest to thousands of citizens who spend their daylight leisure in rambles beyond London's fringe. The nature of the ground below the city is well brought out; but the four sheets of the one-inch map covered by the memoir also include pleasant fields where the outcrops of the strata may be traced. The description of the gravels shows how much may be learned from material excavated in the urban areas, when this is correlated with the terraced deposits of the Thames valley as a whole. The description and classification of stone implements is brought well up-to-date. G. A. J. C.

Lecture Demonstrations in Physical Chemistry. By Dr. S. van Klooster. Pp. vi+196. (Easton, Pa.: The Chemical Publishing Co.; London: Williams and Norgate, 1919.)

DR. VAN KLOOSTER has brought together a number of experiments suitable for lecture demonstrations in physical chemistry. These experiments, to the number of 253, include, in addition to the more obvious experiments such as the determination of molecular weights, a series of thirty experiments on colloids and adsorption, some eighteen experiments on actino-chemistry, and conclude with a short series of experiments in which liquid air is used. When physical chemistry is taught to advanced students, lecture demonstrations are often regarded as superfluous; but with the growing importance of the subject the demand for suitable illustrations is likely to increase. The volume before us will, therefore, be welcomed by many teachers who will find it a considerable help in introducing experimental demonstrations into their lecture courses.

Manual of British Botany: Containing the Flowering Plants and Ferns arranged according to the Natural Orders. By C. C. Babington. Tenth edition, with amended Nomenclature and an Appendix. Edited by A. J. Wilmott. Pp. lvi+612. (London: Gurney and Jackson, 1922.) 16*s.* net.

IN this edition Mr. Wilmott has endeavoured to bring the names up-to-date; and on the vexed question of nomenclature has, so far as possible, cited the author who first gave to the name employed the connotation expressed in these pages. In the appendix have been inserted the more important revisions of genera (*e.g.* Moyle Rogers "Conspectus of the Rubi"), additional species, and, in places, important information connected with the main body of the work; the inclusion of all varieties now accepted—many of which were deliberately rejected by Babington—having proved impossible. For its size and weight (7½ oz.) the manual might be deemed expensive; but it has a value possessed by no other for the serious student of the British flora.

Le Mouvement scientifique contemporain en France. No. 1. Les Sciences naturelles. By Dr. G. Matisse. (Collection Payot. No. 10.) Pp. 160. (Paris: Payot et Cie., 1921.) 4 francs.

THOSE desirous of keeping touch with the recent work of French biologists, but unable to consult the original memoirs, will find here useful epitomes of the results and views of some of the more prominent workers. The first chapter is devoted to Lacaze-Duthiers and the Roscoff laboratory. The subsequent chapters contain summaries (i.) of the work of Yves Delage and Bataillon on heredity, artificial fertilisation, etc.; (ii.) of Houssay's experiments in dynamic morphology, in which those dealing with the shapes of fish are of especial interest; (iii.) of the results achieved by Cuénot, Bohn, and Réné Quinton in their several fields of research; and on the botanical side (iv.) of Chauveaud's work on plant development and transitory tissues; Molliard's investigations of the structural effects of artificial nutrients, and of parasitism; and Matruchot's cultivation of basidiomycete fungi from the spore to maturity.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

On the New Element Hafnium.

THROUGH the courtesy of the editor of NATURE we have been able to see an advance proof of the letter of MM. Urbain and Dauvillier (NATURE, February 17, p. 218), and are glad to have the opportunity to add the following comment:

Our main reasons for believing that the element celtium, the detection of which was announced by Urbain in 1911, is altogether different from the element detected by us and named hafnium, are:

1. Celtium and hafnium show very great differences in their chemical properties. While we have found no difficulty in purifying hafnium preparations from contents of rare earths, the separation of celtium from the rare earths was found by Urbain to be so difficult, that although the detection was announced in 1911, only samples of small concentration have been obtained up to the present time.

2. It has not been possible by means of highly concentrated hafnium preparations to reproduce the characteristic optical spectrum ascribed by Urbain to celtium, and which, together with an investigation of the magnetic properties of his preparation, was the basis of the announcement of the discovery of this element. The result of a closer investigation of the optical spectrum of hafnium will soon be published.

3. The X-ray spectrum of a preparation containing a percentage of an element high enough to measure magnetic properties should show the characteristic X-ray lines of this element in great intensity, altogether different from the exceedingly faint lines found by Dauvillier. Quite apart from the possibility of accounting for these lines as due to a higher order spectrum of other elements, it seems to be very unlikely that these lines should be due to a contamination of Urbain's preparation by a trace of hafnium. Not only as stated in our first letter (NATURE, January 20, p. 79) they do not coincide within the limit of experimental error with our measurements of the wave-lengths of the hafnium X-ray lines L_{α_1} and L_{β_2}, but also the reason given by Dauvillier for not detecting the line L_{β_1}, which is stronger than L_{β_2}, can scarcely be maintained. In fact, our measurements for this line give a value which differs about 3 X-units from the Lu-line denoted by Dauvillier as L_{β_2}', and with the dispersion used it should be easily separated from the latter line.

As stated in our letter in NATURE of February 10, p. 182, hafnium appears in large abundance in zirconium minerals, and we estimate the hafnium content of the earth's crust to be more than one part in 100,000. In the meantime we had the highly interesting information from Prof. V. Goldschmidt in Christiania, that in an investigation of zirconium minerals, in collaboration with Dr. Thomassen, he has discovered a mineral in which hafnium is a main metallic constituent. This has been verified by an X-ray investigation in this Institute of a sample kindly sent to us by Prof. Goldschmidt. On the other hand, an investigation of certain preparations extracted from a titanium mineral from New Zealand and kindly sent to us by Dr. Scott did not reveal any hafnium line. Taking the sensitiveness of the method into account, this mineral cannot contain appreciable amounts of hafnium.

The question discussed by MM. Urbain and Dauvillier which elements are to be ascribed in the family of rare earths, has hitherto been a matter of pure definition. The recent development of the theory of atomic structure, however, has given the question involved an entirely new aspect. The appearance of a group of elements in the 6th period in the periodic table exhibiting very similar chemical properties but quite different magnetic ones could be explained by Bohr on the basis of the fundamental principles of the quantum theory (for particulars cf. Bohr's Nobel lecture, shortly to appear in NATURE). For this atomic theory the properties of the elements in the 6th period of the periodic table have therefore become of great importance. The stimulus to our present investigations was provided by the great difficulty of reconciling this theory with the results announced six months ago by Dauvillier and Urbain. In fact, the existence of an element with atomic number 72 and the chemical properties ascribed to celtium cannot be reconciled with the theory. Our confidence in the theory, however, has been amply justified. For by following up the theoretical deductions we have been led to detect a new element, which is the proper analogue of zirconium and with atomic number 72, present in considerable abundance in the earth's crust. This confirmation of the theory was the deciding factor in our choice of the name hafnium for the new element.

G. HEVESY.

Copenhagen, February 9.

Hafnium and Titanium.

THE black iron sand from New Zealand examined by Dr. Scott in 1915 in which, as he informed the Chemical Society at its meeting on February 1, he found a substance which he is now inclined to regard as probably identical with an oxide of the new element recently discovered by Dr. Coster and Prof. Hevesy of Copenhagen, and named by them hafnium, was doubtless similar in character to the deposit observed to occur in the bed of a rivulet at Tregonwell Mill, near Menaccan, in the parish of St. Keverne, Cornwall, and also in a stream at Lenarth, in the same parish, and in which the Rev. William Gregor, the minister of that parish, who analysed the deposit in 1789, first detected the existence of the element now known as titanium.

The Cornish mineral, a titaniferous iron sand of variable composition, was known mineralogically as menaccanite, and the new element was consequently termed menachin. Similar deposits occur in other parts of the world, and, in fact, are widely distributed. Their characteristic constituents are known variously as ilmenite, iserine, thuenite, hystatite, washingtonite, crichtonite, etc.; the results of analyses of them by Mosander, Marignac and Kobell are to be found in Greg and Lettsom's "Mineralogy," and a list of localities in which they occur is given by Dana. Their composition is very variable, the amount of titanic acid, for example, ranging from 22·2 per cent. to 46·9 per cent. They are all essentially iron titanates, associated with variable amounts of oxides of iron, and, occasionally, of manganese and other substances.

The name titanium was given to the element by Klaproth as the result of his detection of it in rutile and ilmenite, and in ignorance, apparently, of Gregor's prior discovery, although this was announced in Crell's *Annalen* of 1791. Klaproth's experiments were confirmed by Vauquelin and Hecht in 1796. Klaproth subsequently examined menaccanite, and found that menachin and titanium were identical.

The atomic weight of titanium was made the subject of investigation by Rose in 1823, and again in 1829; by Mosander in 1830; by Dumas in the same year; by Pierre in 1847, and by Demoly in 1849. The methods employed were not identical, but they usually

depended upon the analysis of the tetrachloride, which was held to be sufficiently purified by fractional distillation. The results were extremely discrepant, far more so than could be explained by ordinary analytical errors. The values for the atomic weight of titanium ranged from 47 to 56. The determinations have been discussed by Becker, and, independently, by Clarke in the "Smithsonian Collections," and also by Meyer and Seubert. Clarke contents himself with remarking that the atomic weight of titanium is "imperfectly determined," and Meyer and Seubert place α titanium in the list of those elements of which the value is uncertain to within several units.

Pierre's determinations made on the tetrachloride were long regarded as the most trustworthy, and his final value 50·25 was adopted in all atomic weight tables prior to 1885.

The position of titanium in the table drawn up by Mendeléeff, in accordance with the requirements of the Periodic Law, was discussed by him on the occasion of the publication of his famous memoir, when he pointed out that the "law" indicated that its accepted atomic weight, based mainly upon Pierre's work, was at least two units too high (see his "Principles of Chemistry," vol. ii. p. 26). A redetermination made upon the carefully purified tetrachloride and tetrabromide proved that Mendeléeff's prevision was correct (Thorpe, *Journ. Chem. Soc.*, 1885, 47, 108), and the value 48·1, then ascertained, was accepted by the International Committee, and finds its place in all recent atomic weight tables.

That there was an undiscovered element associated with titanium in its various naturally occurring compounds has long been surmised. It is almost impossible to escape the conviction that the extraordinarily discordant values for the atomic weight of titanium obtained by the several chemists above referred to are in all probability to be explained by the presence of an element of higher atomic weight in the material investigated by them. Mendeléeff, in the course of conversation with me, more than once expressed his conviction that a diligent search among naturally occurring titaniferous compounds, or among minerals belonging to the same group of elements as titanium, would be rewarded by the discovery of such an element.

T. E. THORPE.

Whinfield, Salcombe, South Devon.

Insulin.

SIR WILLIAM BAYLISS'S article in NATURE of February 10, p. 188, displays an attitude of friendly criticism towards the Medical Research Council's policy, in expressing their willingness to accept assignment of the insulin patent from the University of Toronto. The fact that an observer so sympathetic, and having so many opportunities of ascertaining the true nature of the position, should give expression to doubt and disquiet, may well arouse misgiving in a wider circle. There are several points concerning which he is clearly under a misapprehension.

(1) Sir William Bayliss, in stating that "there is a strong feeling here"—*i.e.* in this country—"against patenting products of value in the cure of disease," makes an assumption which seems scarcely justified by the facts. I think his statement is wider than his intention. It can hardly be maintained that such feeling is general, in face of the fact that practically every new remedy obtained by synthesis in the chemical laboratory is not only patented, but exploited for the profit of the discoverer or his employers. Sir William Bayliss is probably thinking only of remedies discovered in physiological or pathological laboratories, the patenting of which has, indeed, been discouraged by the facts that such remedies are usually invented by qualified members of the medical profession, with a wholly honourable tradition against secrecy and monopoly, and that their protection by sound patents is, in any case, difficult. It is, however, not logical that we should look askance at one chemist, who patents a process for extracting a hormone, even if he does it for personal gain, and regard with approval another, who makes a large fortune by patenting the synthesis of, say, a new hypnotic.

(2) It is, however, not necessary, in the instance under discussion, to consider the propriety of patenting remedies for gain. Sir William Bayliss's introduction, in this connexion, of the question of rewards for medical discoverers is really quite irrelevant. Whether the University of Toronto expects to make profit out of the patent is a question for its authorities to answer. I am quite certain, however, that, if profit is made, it will not go to the remuneration of the discoverers, but to make good the heavy expenditure in which the insulin investigation has involved the University, and to make provision for further research upon it. The Medical Research Council, I am confident, will make no profit at all from their action in accepting assignment, not even to replace the money they are spending to make this remedy available and to promote investigation of its properties.

(3) The question of profit being excluded, it is obvious that the Council's action could have no other aim than to assist the public in obtaining the remedy under the best possible conditions, and to prevent the dangers and difficulties which might arise if the preparation were left at the mercy of unrestricted commercial exploitation. Sir William Bayliss sees an easy way to secure these ends. "Would not," he asks, "the best way to effect these objects be to announce that the Medical Research Council were prepared to test and certify preparations sent to them?" He sees himself that this might involve "a large amount of work," and suggests large batches and the delegation of testing to firms having facilities. He may be assured that these possibilities have not been ignored; but it must also be said that he does not begin to see the real difficulties. It will suffice to mention one, which is easily overlooked from the arm-chair of the study, or even from the stool of the academic laboratory. The supply of raw material is not unlimited; it is by no means certain that it will prove adequate to the need of sufferers in this country, even if all of it is properly used. The ordinary methods of commerce would involve a vigorous competition for the material, with no guarantee against the purchase of a large part of it, or even the whole, at artificially exalted prices, by firms concerned only to take advantage of the popular excitement, by selling, at high prices, something which could be represented as "Insulin."

Does Sir William Bayliss seriously suppose that such a situation could be met by a friendly offer to test anything calling itself "Insulin," prepared by any one regarding himself as competent, or wishing to have his share in exploiting a public clamour? Given that the enterprise can be confined to firms possessing the necessary equipment of plant and scientific staff, and that they will agree not to raise the price of the raw material artificially by competition, or of the finished product by combination, there is everything to be said in favour of encouraging them to carry out experiments and improve the process. It is possible also to hand on, to firms accepting such conditions, all information, from any

source, which can accelerate production and improve the product. This is, and always has been, the policy of the Medical Research Council. But such a policy has only been made possible, in the existing state of the law, by the Toronto application for patent and the Council's consent to accept assignment.

(4) The most surprising, and the most serious, misunderstanding of the position is revealed by Sir William Bayliss's statement, that "the necessity for any laboratory being unable to do this," *i.e.* to carry out research on insulin—"except by arrangement with the patentees does not seem desirable." I agree that it is not desirable; but the alleged inability is quite imaginary. No such permission is required, but many have sought and have been given help, and many more have received help without seeking. Sir William Bayliss will be familiar with the custom current among scientific workers, of maintaining a certain reticence with regard to work which is unfinished or results which are still in doubt, and even of asking others to keep clear of a certain problem for a time, to avoid duplication. I can state with confidence that, even in that restricted and legitimate sense, there has been no attempt on the part of the Council, or of those working for them, to keep any kind of secrecy or monopoly in this field, so far as pure research is concerned, uncomplicated by questions of personal gain.

In my own department, the whole of our knowledge of this subject has been put freely at the disposal of other pure research workers—not only what has come to us in connexion with the patent, but what has resulted from our own investigations. Sir William Bayliss acquits the Council of "any desire whatever to obstruct such research." I think he might safely allow himself to go a little further, and recognise that their policy in this matter, and its interpretation by those working for them, has resulted in a quite unusual freedom of assistance to research, with both information and material.

Multiple Resonance.

SIR RICHARD PAGET'S skilfully demonstrated lecture at University College on October 18, 1922, the substance of which is given in NATURE of January 6, is not less interesting as giving a very simple account of the nature and formation of speech sounds, than as showing how far-reaching and diverse are the applications of "multiple resonance" in acoustics.

Boys (NATURE, vol. 42, p. 604, 1890) made use of a special kind of double resonator in constructing a very sensitive form of "Rayleigh disc," and Rayleigh extended his theoretical consideration of double resonators given in his "Theory of Sound," vol. ii. p. 190, to show that "the condensation in the second resonator may be made to exceed to any extent that in the first, by making the second resonator small enough" (Rayleigh, *Phil. Mag.* xxxvi. 231-4, 1918).

Following some preliminary experiments by Prof. Callendar and Major Tucker in 1918, Capt. E. T. Paris employed the double resonator for the purpose of increasing the sensitivity of the hot-wire microphone originally devised by Major Tucker and also of extending the range (in pitch) of maximum sensitivity.

For a single resonator the response curve is a sharp peak, but with a proper design of double resonator the two peaks (characteristic of such resonators in general) may coalesce, so to speak, into what is practically one broad flat-topped peak. In the accompanying diagram (Fig. 1) the dotted line gives a typical response curve for a single resonator, and the full line is typical of the curve obtained when a resonator of suitable proportions is added, to form a double resonator.

Paris has shown how the form of the resonance curve can be varied with tuning of the component resonators, from equal response to each of the two natural tones, to the case of much stronger response to one than the other. The double resonator of Boys appears to have been of the latter kind. "A doubly-resonated microphone of the type described may be

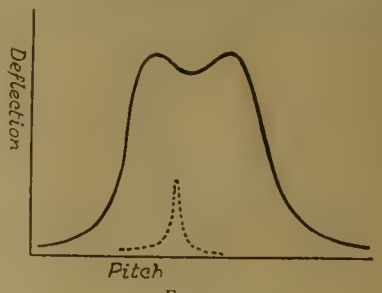

FIG. 1.

more than a hundred times as sensitive (to one of its resonant tones) as a suitably tuned singly resonated microphone with an aperture similar to that of the inner resonator" (E. T. Paris, Proc. Roy. Soc. A, vol. 101, 1922).

The present writer, independently, developed a form of *multiple* resonator to provide a recording system for the Gramophone Co., Ltd., Hayes, Middlesex, having a uniform response over a very wide range—namely four octaves. For so wide a range (129 to 2069 vibs./sec.) the source of sound was a series of stopped diapason, wooden organ pipes, giving fairly pure tones of uniform intensity as judged by the trained ear. The amplitude of vibration of the diaphragm—or of the point of the wax-cutting needle—was observed by means of exceedingly small mirror attachments, the best of which was similar to D. C. Miller's "phonodeik" (Miller, "Science of Musical Sounds," Macmillan). It was possible so to adjust the ten to twenty components of the multiple resonator that the response curve (plotted amplitudes against pitch) would conform very closely to a curve such as that determined by the theoretical constant intensity relation, $a^2 n^2 = \text{constant}$, without a serious loss of sensitivity.

A resonator of simple form with yielding walls is a double resonator. Rayleigh, on the suggestion of Clerk Maxwell, considered the case of a sphere with non-rigid walls (Phil. Trans., 1871, p. 87) and showed that it has two natural periods, being a system of two degrees of freedom, like an ordinary double resonator. Similarly, a rigid resonator of conical form with a diaphragm mounted at the narrow end is a double resonator, and so we get an explanation of the fact that the octave interval between the first and second partials for the conical resonator alone, is increased by as much as a tone if the natural frequency of an attached diaphragm falls between the frequencies of the partials.

Multiple resonance will perhaps account for the remarkable evenness of response and the characteristic quality of tone given by the resonating body of good violins. Helmholtz ("Sensations of Tone," 1885 edition, p. 87, Ellis translation) found two tones of greatest resonance on a violin by Bausch, one between 264 and 280, and the other between 440 and 466 vibs./sec., when he tested it by placing the

ear against the back of the violin and playing a scale on the pianoforte. Ellis (*loc. cit.* footnote) gives details of elaborate tests made by sounding tuning-forks over the ∫ holes of a number of the best and oldest violins. There were at least two maxima in all cases, but the best specimens gave almost equal response to his forks from 240 to 560, and in the case of Dr. Huggins's Stradivari of 1708, described as one of the best Stradivari, "every fork was more or less reinforced; there was a subordinate maximum at 252; a better at 260-268 vib.; very slight maxima at 312, 348, 384, 412, 420, 428 (the last of which was the best, but was only a fair reinforcement), 472-480, but 520 was decidedly the best and 540 good. No one fork was reinforced to the extent it would have been on a resonator properly tuned to it, but no one note was deteriorated."

The peculiar shape of the body of a violin is such as to give double resonance even if the walls were rigid. Taking into account the vibrations of the wooden walls as well, we have a multiple resonator which will no doubt give an even response over a wide range in the best violin.

Just as Sir Richard Paget's double resonator modifies an artificial larynx to give vowel sounds, so the multiple resonator—the violin body—determines the valued quality of tone of the violin.

Multiple resonance gives promise of being a very fruitful field of research in acoustics.

Destruction of the Polarisation of Resonance Radiation by weak Magnetic Fields.

THE earlier studies of the resonance radiation of mercury vapour in exhausted quartz tubes by one of the present writers showed no traces of polarisation, even when the exciting light was polarised.

Recent experiments by Lord Rayleigh apparently indicated that polarisation existed in that part of the excited column at some little distance from the window at which the beam entered; in other words, when the excitation was produced by light from which the core of the 2536 line had been removed by absorption. This observation was not verified in experiments made by one of us last spring and published in a recent number of the *Philosophical Magazine*. The polarisation was found to be strong and of uniform percentage right up to the window at which the beam entered.

On commencing a further study of the phenomenon we found it impossible to produce as strong polarisation as was indicated by the earlier experiments, and after varying the conditions in every conceivable manner we finally found that the disturbing factor was the magnetic field of the earth, the polarisation rising to a very high value (90 per cent.) when the magnetic field of the earth was compensated by a large solenoid carrying a feeble current. In the absence of the solenoid the percentage of polarisation dropped to fifty or less.

This appears to be a new magneto-optic effect, and is manifested only when the magnetic field is parallel to the magnetic vector of the exciting light and perpendicular to the beam of exciting rays. A field of only five or six times the strength of the earth's field practically destroys the polarisation. Discrepancies found previous to the discovery of this effect were due to the fact that in some cases the apparatus faced north and south, and in others east and west. Lord Rayleigh's observation was doubtless due to the stray field of the electro-magnet which was used to flatten the discharge against the wall of his quartz lamp.

Volcanic Activity in Iceland and Long Distance Transport of "Dust."

WITH reference to the communication on this subject made by Prof. Grenville Cole to NATURE, November 11, 1922 (vol. 110, p. 635), the following additional remarks may be of interest.

In the *Deutsche Fisherei Zeitung* for November 14, 1922, occurs a note which may be summarised as follows: A Geestemunde steam trawler, the *Tyr*, while returning from her last trip to Iceland, experienced a fall of ashy material on her deck. This occurred while at a distance of at least 400 sea miles from Iceland. It is stated that the material was doubtless from Hecla, and though no date of the occurrence is given, it is known that the vessel made Geestemunde on October 25. A communication from the British Consul at Thorshavn also deals with this matter, and reads as follows:

". . . beg to inform you that on October 6 this sandstorm was observed on these islands. The weather was fine that day, but clouded, and the sky had a red-grey colour, and I remember the feeling of getting fine sand in my eyes while being in a rowing boat that morning, and going home to lunch my wife showed me some fine dark grey sand lying in the windows, which had been open that morning.

"I may add that a telegram received from Iceland that day gave the news of volcanic eruption in Iceland."

For these two reports I am indebted to Mr. G. T. Atkinson, district inspector of fisheries, Eastern Area.

The Wegener Hypothesis and the Origin of the Oceans.

READERS of NATURE have been served with good reviews and discussions on the Wegener hypothesis, and it may therefore be of interest to point out that, so far as it relates to the origin of the Atlantic Ocean, this hypothesis was anticipated by previous writers, more especially by Osmond Fisher and W. H. Pickering. Fisher's views are well known to students of geodynamics, and Wegener himself refers to papers by W. H. Pickering and F. B. Taylor; but only by reading the accounts given by these authors can one realise how completely they forestalled Wegener, so far as the origin of the Atlantic by the westerly drift of the Americas is concerned.

It was to accommodate Sir George Darwin's views on the origin of the moon that Osmond Fisher suggested, first in NATURE (1882, vol. 25, p. 243) and afterwards in the second edition of his "Physics of the Earth's Crust," that the Pacific Ocean is a scar and depression on the earth's surface, left by the detachment of the moon. The following are Fisher's words (p. 380): "The hole would be filled up by the influx of the molten substratum from beneath and around. The remaining crust would separate into larger and smaller fragments, and partly float towards the cavity. Thus when the

newly exposed surface of the molten substratum again solidified, a fresh crust, of greater density than before, would be formed out of the heavy substratum over the middle of the area, where the hollow had been made, and also in the channels between the fragments which had floated towards it; the Atlantic being the chief of these channels."

In his paper on "The Place of Origin of the Moon—The Volcanic Problem" (*Journ. Geol.*, 1907, vol. 15, p. 23) W. H. Pickering elaborates the view previously propounded by Osmond Fisher; and although he makes no acknowledgment, we may safely infer that, directly or indirectly, he owed the idea to Fisher. The following quotation shows how remarkably close Pickering got to the statement of the Wegener hypothesis: "A curious feature of the Atlantic Ocean is that the two sides have in places a strong similarity. . . . When the moon separated from the earth, three-fourths of the crust was carried away, and it is suggested that the remainder was torn in two to form the eastern and western continents. These floated on the liquid surface like two large ice-floes."

In his paper on the "Bearing of the Tertiary Mountain Belt on the Origin of the Earth's Plan" (Bull. Geol. Soc. America, 1910, vol. 21, p. 179) F. B. Taylor remarks: "Thus we may conclude, at least provisionally, that it was North America that moved away from Greenland, and not *vice versa*."

If the view that the American continent has drifted away from Europe and Africa during Mesozoic and Tertiary times comes to be established, which seems highly improbable, it will no doubt owe much to Wegener, and will be associated with his name in this special sense; but Osmond Fisher is clearly the author of the hypothesis of continental drift, so far as it applies to the problem of the origin of the Atlantic Ocean. The tectonic evidence provided by a study of the Atlantic floor, however, indicates that its submergence in large part during Tertiary times has been effected by the ordinary process of subsidence, and that, *pari passu* with this subsidence, considerable areas of Eurasia and Africa, which were previously submerged, have been raised above sea-level. Indeed, as Suess has pointed out, the evidence seems to show quite conclusively that, throughout the Mesozoic and Tertiary eras, a mediterranean ocean of the Atlantic type has in a large way dissected the continental masses and absorbed their drainage, although its orientation has changed.

These broad geotectonic considerations seem to be utterly at variance with the claim based by Wegener on the jig-saw relationship of the opposite sides of the Atlantic; and there can be little doubt that, to a large extent, they dispose also of the Fisher hypothesis of continental drift, so far as the origin of the Atlantic is concerned.

It should be remembered, however, that Fisher's views on continental drift were based on the hypothesis he entertained as to the condition of the earth's interior. There are profound differences between the Atlantic and Pacific Oceans. Astronomers tell us that the Fisher hypothesis as regards the Pacific is a very good one, and to this may be added the claim that, in large measure, it fits the facts known to us concerning the petrology and tectonics of the earth. While, therefore, declining to accept Fisher's hypothesis of continental drift to explain the origin of the Atlantic, we may accept provisionally his view that the Pacific owes its origin to the detachment of the moon, especially as some hypothesis seems to be necessary to explain the heterogeneity of the earth's crust.

T. CROOK.

Aster tripolium on Salt Marshes.

I NOTICE in the article on Belgian botany in NATURE of January 20, p. 97, a statement which reminds me of some observations of mine at Dovercourt, near Harwich, in 1908. The article says that a fringe of the purple-rayed form of *Aster tripolium* occurs between the salt marshes, occupied by the yellow form, and the more fertile, less saline, soil. At Dovercourt there are fields overflowed by the sea at every high tide, but still showing signs of former cultivation. The specimens of Aster growing here were all fleshy and rayless. Separated from these fields by earthen dykes were other fields, which showed no signs of being flooded at any time. Here the Aster was always thin and wiry in the stalk, and bore a well-developed ray.

The Cause of Anticyclones.

WITH reference to Miss Catherine O. Stevens' letter (NATURE, February 3, p. 150) on this subject, it is clear that there could be no high-pressure areas unless there were low-pressure areas as well.

It is also quite clear that the pressure distribution at any moment depends upon the flow of the winds, the inertia of the air, and the rotation of the earth. But the atmosphere is a viscous substance, and the friction resulting from its viscosity would soon bring the whole mass to rest were there no continuous source of power to keep it moving.

It is generally agreed that the source of power which maintains the circulation of the atmosphere is difference of air density resulting from difference of temperature. The problems to be solved are—what is the exact distribution of temperature throughout the atmosphere? will the actual temperature distribution account for the winds? and how are these temperature differences maintained?

R. M. DEELEY.

Tintagel, Kew Gardens Road, Kew, Surrey,
February 2.

The High Temperature of the Upper Atmosphere.

IN a letter in NATURE of February 10 Mr. Whipple suggests that a comparatively sudden increase in temperature of the air at a height of about 60 kilometres, such as observations of meteors render likely, would account for the well-known zones of audibility and silence. This seems to us a promising line of investigation, which might enable one to determine annual variations of temperature, if any. We had already examined the possibility of using meteor observations for this purpose, but they are as yet scarcely sufficiently accurate to enable one to determine the small differences involved. The same applies to the suggestion of Mr. Deeley in NATURE of January 20.

In the last paragraph of his letter Mr. Whipple suggests that the estimates which we made of the temperature on theoretical grounds require modification, as the atmosphere is exposed to the sun only during the day-time. We need scarcely point out that this fact had not escaped our attention and was allowed for in the coefficients of the formula actually used.

The Bicentenary of Sir Christopher Wren.

By Eng.-Capt. EDGAR C. SMITH, O.B.E., R.N.

THOUGH during the celebration, next week, of the bicentenary of Sir Christopher Wren the main interest must needs centre around his great work as an architect, his position as one of the representative men of science of the seventeenth century should not be overlooked. Five years younger than Boyle, and ten years the senior of Newton, Wren had as his contemporaries Wilkins, Hooke, Goddard, Willis, Sydenham, Flamsteed, and Barrow. The year Wren was born Galileo was writing his famous "Dialogues," and in the subsequent developments which made England the scientific centre of the world Wren was one of the pioneers. While quite a youth Wren joined the group of philosophers who met at the lodgings of Wilkins or Boyle at Oxford, and at twenty-five he became Gresham professor of astronomy. Four years later he returned to Oxford as Savilian professor. The Royal Society owed much to him, and he was one of its earliest presidents. Perhaps not such an extraordinary boy as Young or Hamilton, his genius was recognised from the first. Barrow indeed, in 1662, referred to him "As one of whom it was doubtful whether he was most to be commended for the divine felicity of his genius or for the sweet humanity of his disposition—formerly as a boy a prodigy; now as a man a miracle, nay, even something superhuman."

Wren was born at East Knoyle, in Wiltshire, on October 20, 1632. His grandfather, Francis Wren, was a mercer in the city of London; his father, also Christopher Wren, was rector of East Knoyle and dean of Windsor. Another son of Francis was Matthew Wren, bishop of Hereford, Norwich, and Ely; a stiff-necked prelate who spent more years in the Tower than he need have done. Wren's mother died when he was young, but his father survived till 1658. At nine Wren was sent to Westminster school, then under the famous Busby. From Westminster, after an interval, probably due to the unsettled state of affairs—Oxford then having more soldiers than students—he passed to the University and was entered as a gentleman commoner of Wadham College, of which Wilkins was the warden. He graduated B.A. in 1651, M.A. in 1653, and that year became a fellow of All Souls, holding his fellowship until 1661, the year he was appointed Savilian professor.

Like most students of his day, Wren roamed over many fields of learning. With a talent for fine and accurate drawing he combined a manipulative skill which was the envy even of Hooke. These found employment in many ways. For Willis he made the elaborate drawings for a work on the anatomy of the brain. He was one of the first to inject liquids into the veins of animals. Writing to Petty in 1656 he says, "The most considerable experiment I have made of late is this;—I injected wine and ale into the mass of blood in a living dog, by a vein. . . . I am in further pursuit of the experiment, which I take to be of great concernment, and what will give great light to the theory and practise of physic."

Wren's two professorships cover a period of sixteen years—1657 to 1673. The Gresham and Savilian chairs were the first mathematical and astronomical professorships founded in England. One or the other had been held by Briggs, Bainbridge, Turner, Greaves, Gellibrand, and Gunter. Gresham College, London, was the old mansion of Sir Thomas Gresham, which stood on a site stretching between Bishopsgate Street and Old Broad Street. The lodgings of the professors of music and physic and the Reading Hall were close to Bishopsgate Street, but the quarters of the other professors were situated around a large quadrangle. An interesting sketch of the college is given in Weld's "History of the Royal Society." Wren's appointment was owing to Lawrence Rooke exchanging the chair of astronomy for that of geometry, the transfer being due "to a conveniency of the lodgings which opened behind the Reading Hall." Wren's lectures were read the same day as Rooke's and attended by the same auditors. He discoursed on telescopes, eclipses, the planet Saturn, and meteorology, and to this period belong his demonstrations concerning cycloids.

In February 1661 Wren resigned both his Gresham professorship and his fellowship of All Souls and returned to Oxford to succeed Seth Ward as Savilian astronomer. In this position he continued to investigate a wide range of subjects, suggesting self-registering weathercocks, thermometers, and rain-gauges; constructing telescopes for measuring small angles, and making experiments with pendulums. In 1668 he showed his experiments to illustrate the laws of motion by the collision of balls. Newton afterwards writing of the laws of motion said: "Dr. Christopher Wren, knight; John Wallis and Christian Huygens, who are beyond comparison the leading geometers of this age, arrived at the laws of the collision and mutual rebound of two bodies; but their truth was proved by Dr. Wren by experiments on suspended balls in the presence of the Royal Society."

It was while Wren still held the Gresham professorship that the Royal Society came into existence. The first official record was a memorandum of November 28, 1660. This gave the names of the persons who had "mett together at Gresham Colledge to heare Mr. Wren's lecture." After the lecture "they did, according to the usual manner, withdrawe for mutuall converse," and it was agreed upon that "this Company would continue their weekly meeting on Wednesday, at 3 of the clock in the tearme time, at Mr. Rooke's chamber at Gresham Colledge; in the vacation, at Mr. Ball's chamber in the Temple." Wilkins was chairman on this occasion. At the next meeting, December 5, Sir Robert Moray, the first elected president, brought word that the King approved of the Society and would be ready to give encouragement to it. The minutes also record that "Mr. Wren be desired to prepare against the next meeting for the Pendulum Experiment." On December 19 Mr. Wren and Dr. Petty were "desired to consider the philosophy of Shipping, and bring in their thoughts to the company about it."

The Royal Society was further indebted to Wren for drawing up the preamble to the charter of Incorporation in which Charles II. states his determination "to grant our Royal favour, patronage and all due encouragement to this illustrious assembly and so beneficial and laudable an enterprize." The charter was first read on August 13, 1662, and two years later Wren gave an address on the objects to which the Society should devote its energies. He exhorts the members "not to flag in the design since, in a few years, at the beginning, it will hardly come to any visible maturity. . . . The Royal Society should plant crabstocks for posterity to graft on." Lord Brouncker became the first president of the Society after its incorporation, Sir Joseph Williamson succeeded him in 1677, and Wren, who had been knighted in 1673, was elected president in 1680. Boyle had previously declined the honour through "a great tenderness in point of oaths." Wren held office till St. Andrew's Day, 1682.

So far, attention has been directed only to Wren's scientific activities. Soon after his return to Oxford, in 1661, he was invited by Charles II. to act as surveyor-general of His Majesty's works, and from this time dates his career as an architect, which ultimately raised him to the head of the profession. The first building designed by him was the chapel of Pembroke College, Cambridge, erected by his bishop-uncle as a thank-offering for his liberation from the Tower. His next building was the Sheldonian Theatre at Oxford. In 1665 he spent six months in Paris studying the Louvre and other buildings, returning home, as he said, "with nearly all France upon paper." In 1666 came the great fire of London, and with it Wren's opportunity. From September 2 to September 8 the flames swept across the city, and four days later Wren laid a plan for its rebuilding before the King. Immediately afterwards he was appointed "surveyor-general and principal architect for rebuilding the whole city; the cathedral Church of St. Paul; all the parochial churches . . . with other public structures." Wren was then but thirty-four, and in the remaining fifty-seven years of his life he not only designed and erected many important private and public buildings, but some fifty London churches, and also his great masterpiece, St. Paul's Cathedral. Several years were occupied in demolishing the ruins of old St. Paul's, and it was not until 1675, the year Wren built Greenwich Observatory, that the foundation stone of the new cathedral was laid. Thirty-five years later Wren's son put the topmost stone of the lantern into position.

Of the city of London as Wren knew it in his Gresham days but little remains. Wren, if he had had his own way, would have changed its very plan. It was his intention to cut two great arteries from east to west and another from north to south. At the intersections of these thoroughfares would have stood the new St. Paul's and the great public offices. He further designed that a noble quay should flank the Thames from the Tower to the Temple. For better or for worse his plans proved unacceptable, and so to-day it is yet possible to follow some of the footsteps of the old philosophers and to visit their memorials.

Though it escaped the fire, all trace of Gresham's mansion has long since disappeared. St. Helen's Church—sometimes called the Westminster Abbey of the City—where the inmates of Gresham College worshipped, still stands, and within its walls lie the remains of Hooke, Goddard and Gresham. Three of Wren's predecessors in the chair of astronomy, Gellibrand, Foster, and Gunter, were buried in St. Peter le Poer, which stood in Old Broad Street, while Rooke, "the greatest man in England for solid learning," was buried in St. Martin Outwich, from which the monuments were some fifty years ago removed to St. Helen's. Rooke died just before the Royal Society received its charter. Greaves, another Gresham and Savilian astronomer, was buried in St. Benets; John Collins, "the attorney-general of the mathematics," in St. James' Church, near Southwark Bridge, while John Wilkins, first secretary of the Royal Society, and from 1668 bishop of Chester, who died in 1672, was buried in St. Laurence Jewry. This was one of the churches rebuilt by Wren. Wilkins had been rector of the church, and on one occasion he invited Barrow to occupy the pulpit. Barrow preached so well that Richard Baxter declared he "could willingly have been his auditor all day long."

Wren himself lies in the crypt under the south aisle of the choir of St. Paul's. He died on February 25, 1723, and was buried on March 5. The well-known quotation from his epitaph: "Si monumentum requiris, circumspice," now to be seen over the north door of the cathedral, was first carved on the choir screen by Robert Mylne, the builder of the first Southwark Bridge and surveyor of St. Paul's, who lies close to Wren in the crypt.

The grand committee formed by the Royal Institute of British Architects and other bodies interested, to celebrate the bicentenary of the death of Sir Christopher Wren, has arranged for a public commemoration service in St. Paul's Cathedral, on Monday, February 26, at 2.30 P.M., in the course of which an address will be delivered by the Very Rev. W. R. Inge, Dean of St. Paul's. The members of the grand committee, accompanied by the Lord Mayor and Sheriffs, will proceed afterwards to the crypt, where Mr. Paul Waterhouse, president of the Royal Institute of British Architects, and an attaché from the American Embassy in London, on behalf of the Architectural League of New York, will lay wreaths upon the tomb of Sir Christopher Wren. In the evening a Christopher Wren commemoration banquet will be given by the Royal Institute of British Architects at the Hotel Victoria, Northumberland Avenue, and commemorative addresses, dealing with the life and work of Wren, will be delivered.

In addition to these celebrations there will be exhibitions illustrating Wren's work, at the Galleries of the Royal Institute of British Architects, 9 Conduit Street, W.1, on February 26-March 3, and at the Museum, Public Record Office, Chancery Lane, W.C.2, both of which will be open free of charge to the public.

Another interesting proof from overseas of regard for the memory of the great London architect comes from the Architectural Institute of British Columbia, which has arranged to hold, in the largest Anglican church in Vancouver, a memorial service on exactly similar lines to the service which will be held in St. Paul's Cathedral on February 26.

Absolute Measure and the C.G.S. Units.

By Sir GEORGE GREENHILL.

"WHAT is the matter with physics training for the engineer?" is a question asked to-day. The engineer will answer, "It is the C.G.S. source of arrogance and tyranny," following him even into the engineering laboratory, and his calculations in hydrostatics. He has no use for such minute units, as he works always to terrestrial gravitation measure of his world of existence, and C.G.S. is thrown aside as soon as the young engineer, gunner and navigator is liberated from the tyranny of the lecture and examination room, and he is free to talk and calculate in all the old units familiar to generations.

These C.G.S. units are described in Halsey's "Handbook for Draftsmen" as a "Monument of scientific zeal (misplaced) combined with ignorance of practical requirements." "The object of Weights and Measures is to weigh and measure, not merely to make calculations."

No wonder Prof. Hudson Beare maintained at the British Association at Hull the desirability of keeping the mathematics of the engineer distinct from the examination needs of the Science and Art, or even medical student in his research of a diploma, and that the teacher of engineers should preferably be an engineer himself. If he has to teach physics, it should be industrial physics, in their application on a large scale to constructional needs.

Mach pleaded age and infirmity for taking no hand in the translation of his work, and gave the translator a free hand. The opportunity was seized of making him sponsor of the C.G.S. system, and no other, by the ardent disciples of the Open Court. We find the same fervent advocacy of C.G.S. in our scientific schools over here, compelling even the engineering students to use their microscopic units to the exclusion of all others employed in his practical life.

A rival system, M.M.S. (millimetre—milligram—second), still more minute, was proposed in Germany, and is mentioned by Mach, but this was ironical. In France, Olivier, whose work was reviewed lately in NATURE, is pushing the M.T.S. system (metre—tonne—second) as better adapted for large scale work.

The M.K.S. (metre—kilogramme—second) system would suit most practical requirements, but this is rejected by the purist in units because it makes the density of water 1000, kg/m^3, instead of unity. But the advantage here is in keeping the air buoyancy in sight, as a correction of about 1·25 on the last figure of the absolute density, *in vacuo*, as it ought to be tabulated. Suppose it was required to weigh 1 lb. or 1 ton of hydrogen in the scales for an airship; describe your procedure.

Absolute measure was first introduced into dynamical teaching under Prof. Tait in Edinburgh, although Tait never carried his Glasgow colleague with him to a full extent. Gauss had initiated the idea previously as essential in magnetic measurement all over the world.

Tait told us the idea struck him in his struggle with the Definitions in Chapter II of his "Dynamics of a Particle"; and then it burst on him as a revelation of the way out of a theoretical difficulty always a puzzle to him.

The idea fructified, and to-day we find absolute measure universal in all theoretical physics, and the engineer is blamed for sticking to his old gravitation units for mechanics. The electrician, however, is compelled to work absolute in his cosmical electromagnetism, broadcasting his theoretical results, depending only indirectly on the gravitation of the earth.

In Tait's procedure a change was made in the unit of what was then called mass, changing it from a vague *sui generis* into the Imperial Standard Pound, and then $P=Mf$ implied a new unit of force, for which the name poundal was afterwards discovered, such that the heft of 1 lb. weight was g of these units, poundals. The poundal was thus $1/g$ of the heft-weight of 1 lb., say 1/32, or half an ounce in round numbers. This unit was much too small for the engineer; he has refused to have anything to do with absolute measure, and jeers at the pedantry of calling the poundal a unit of weight, pointing to the precise language of the successive Acts of Parliament, from Nebuchadnezzar and earlier, down to our day.

WEIGHTS AND MEASURES ACT, 1878.

Imperial Measures of Weight and Capacity.

13. The weight *in vacuo* of the platinum weight mentioned in the first schedule of this Act and by this Act declared the imperial standard pound shall be the legal standard measure of weight and of measure having reference to weight and shall be called the imperial standard pound and shall be the only unit or standard measure of weight from which all weights and all measures having reference to weight shall be ascertained. [*N.B.*—No word mass occurs.]

Any person who sells by any denomination of weight or measure other than one of the imperial weights or measures or some multiple or part thereof, shall be liable to a fine not exceeding forty shillings for every such offence. Printer and publisher are liable for any act in contravention of this section.

So any one giving weight in poundals, in print or writing, would be liable to this fine. No mention is made in this Act of barometer or thermometer reading, required in the definition of the gallon, cubic measure; weight *in vacuo* covers all such ambiguity of its measure, inserted for the first time in the draft of this Act; the omission was a source of great trouble when the need arose for a new Standard Pound.

Not a word in the Act about the attraction of the earth on the pound weight. Nothing is said about the pressure on the bottom of the box containing the pound weight, and the influence of local g, however it may vary down a mine, or up in the air, or away into space from one end of the world to the other.

The pound weight does not alter, brought out of its vacuum into the atmosphere, or even if it was carried away into space to the other end of the universe; it always remains the lump of platinum defined in the Act. At least this was the current belief until quite recently, before a distinction was made between *Ruhmasse* and *Masse in Bewegung*.

If, however, the weight of a pound is to mean something quite distinct from the pound weight, as the force with which it is attracted by the earth, the confusion of language and measurement is intolerable.

It is not correct to say the word weight is always to be reserved, strictly speaking, for the subsidiary meaning of earth attraction, as the word was in use long before such distinction was made or understood, and is to be found in ordinary language and writing, *e.g.* in Shakespeare, the Bible, and other of our classics, in both senses, but usually in the meaning of the Act of Parliament.

The latest discoveries of atomic theory have forced a reconsideration of former definitions of fundamental units, considered unassailable on the Newtonian doctrine. Language again has failed to recognise these new distinctions. C.G.S. units are displaced in the relativity theory, where the unit of time is nearly 1000 years, instead of our terrestrial second, adopted to keep *g* down to a reasonable figure, 981, or 32.

"Space-Time-Matter" of Hermann Weyl will give some idea of the latest lofty ideas of the universe, beyond the scope of these humble elementary remarks in defence of the old Newtonian mechanics—all the engineer has, so far, to guide him in the design of the steamship, locomotive, and flying machine. Here he is forced to adopt some immediate line of action, leaving the abstract theorist to pursue his speculations at leisure. The engineer must deliver the goods to time.

The *sui generis* mass $M = W/g$, Mach's terrestrial mass, implies unit mass of *g*, lb.; Perry proposed for it the name "slug," about a 32 lb. shot. But slug in gunnery means any irregular piece of lead, cut off a church roof in civil war, and rammed down a fowling piece. It is curious to find *sui generis* mass in slugs still lurking in the engineers' table of moment of inertia of a body; it has even been found by force of habit in a cross-section area for moment of stiffness of a beam.

There is too much of the mere algebraical literal calculus in the presentation of dynamical theorems. Quantities receive a label, M, W, *g*, *v*, *s*, *t*, as in mere algebra, and this letter label is stuck on the quantity for identification, without sufficient explanation of the measurements required to translate the label into the description of an actual body, or its behaviour in motion and associated measurement.

But the writer of the usual text-book is obliged to keep in mind the needs of his class in preparing to meet the examiner, or is on the road to be an examiner himself in his turn, and his book adopted. So the round goes on, and a curious jargon has arisen, cultivated by the schoolmaster and despised by the engineer.

Darboux surprised our company once by retailing the well-known story of the French Minister of Education, pulling out his watch and boasting how at that moment the same lesson was in progress in all the schools in France. I was so bold as to cut in—"Mais, il y a une suite." "Quelle suite?" "Le ministre a continué,—du même traité, de moi."

The Hospitalier notation is a ready escape from confusion when the derived unit appears, involving two or more of the three fundamental units. Then a velocity in feet or centimetres per second is indicated by *v*, ft./sec. or cm./sec., and an alteration of velocity per second by ft./sec.^{2} or cm./sec.^{2}; thus $g = 32{\cdot}2$, ft./sec.^{2}, or $9{\cdot}81$, m./sec.^{2} So, too, for density, in lb./ft.^{3}, gm./cm.^{3}, kg/m.^{3}, t./m.^{3}. A moment of inertia, Wk^2, would be in lb./ft.^{2}, and so on. But the adoption of this Hospitalier system is still very slow, although accepted by a resolution of the Paris Electrical Congress, 1880, and again at Frankfurt, 1891.

Although absolute measure of force is insisted on in all C.G.S. records, there is no accurate measurement of force except first in the gravitation unit of the gravity field, as with the Current Weigher-Balance; and after the experiment is complete, the factor *g* is to be supplied, but often forgotten.

Rayleigh appears to be writing feelingly, quoted in *Engineering*, July 4, 1919: "When a problem depends essentially on gravity, *g* makes no appearance. But when gravity does not enter at all, *g* obtrudes itself conspicuously, and requires to be kept carefully in its proper place" (as in electro-magnetic and elastic measurement).

All matter is transparent to gravity: there is no escape from it on the surface of the earth. In the work of the engineer to combat the powers of Nature, gravity is the force he is up against, and the strength of it provides him with the unit the engineer will never discard, as capable of immediate exact measurement. He will never abandon his gravitation units for such minute substitutes in the C.G.S. system, useful only for passing an examination, or for microscopic physical measurement.

Weighing and measuring must be carried out in a gravity field, and not *in vacuo*; the experimenter must be allowed to breathe in a warm room during a long careful measurement. The factor *g* is inserted after the work is over, for calculation and record in absolute measure, and the C.G.S. system was invented to make calculations and tabulate them, not to weigh and measure, as Halsey pointed out.

The metric system is a legacy of the French Revolution, when all ancient tradition was swept away and the world to be started going afresh. Time and angle were to be decimalised with French logic. The quadrant was divided into 100 grades, each of 100 centesimal minutes; and a minute on the meridian was made into the kilometre—the unit of distance. But sexagesimal clocks, watches, and chronometers were not to be thrown into the sea for such a theoretical fad as centesimal time; and the ridiculous official names assigned to the days of a decimal week excited derision. Any attempt was bound to fail to bring music into line with the metric system, by a decimalisation of the octave.

Elsewhere the metric system has taken a firm hold in the civilised world, as a means of cosmopolitan commercial intercourse, and must be accepted. But the sailor will not surrender his cosmopolitan sexagesimal measure, of time and angle, inherited from the Chaldæan astronomer, and he continues to graduate the quadrant into ninety degrees, and the degree into sixty minutes, and he takes the sexagesimal minute of latitude on the meridian as his unit of length, and calls it a mile, geographical (G), nautical (N), sea (S), or Italian, in the old books.

The sailor then starts a decimal subdivision of the mile, dividing it into 10 cable, and the cable into 100

fathom. Geodetical measurement makes this fathom a little more than 6 ft.,—6·08, say 6 ft. and 1 inch over. Longitude he measures on his chronometer, giving sexagesimal time of 24 hours (h.) in the day, an hour of 60 minutes (m.); and a minute of 60 seconds (s.); four seconds of longitude = one minute of longitude at the equator, or a mile, an easy range of eyesight. The schoolmaster cuts the fathom down to 6 ft. exactly, and would sweep it away as a useless load on the schoolboy's memory, although universal in sounding, as in

"Full fathom five thy father lies."

The schoolmaster has his eye, too, on the suppression of all the ancient measures of agriculture,—furlong, rod, pole, perch, rood, chain, ell, palm, hand. But the chain as the length of the pitch at cricket is too sacred to be assailed. And what is the height in C.G.S. centimetres of a horse x hands high? He is obliged to cling to the mile, the statute, land, military mile, of 8 furlongs, 80 chains, or 1760 yards.

It is unfortunate the sailor carried the world mile on to his own unit, perhaps under a mistaken idea that the two miles were undistinguishable. Newton was arrested in his speculation on gravity by falling into this error. The land soldier mile is the one entitled to its name as the length of 1000 paces (*passus*, not *gradus*), *millia passum*, M.P. on the Roman milestone, covered in marching along the road, making 5·28 ft. the double pace of the Roman soldier; this is cut down to 5 ft. in our modern drill book, and less still in the metric equivalent of the French soldier.

It is strange to read to-day in the "Admiralty Manual of Navigation," 1914, page 1, the earth is described as an oblate spheroid, greatest and least *diameter* 3963, 3950 miles (military, soldier, statute). In navigation the surface of the ocean is always treated as a perfect sphere, and of girth $360 \times 60 = 21600$ sea miles (S), making the *radius* of the sphere 3438 S miles, the length of the radian along a meridian. Besides the solecism of mentioning the military land mile as a measure in navigation, the real dimensions of the earth are double as stated in the Manual. Can we wonder then at an Admiral sending himself and his flagship to the bottom by a confusion between radius and diameter?

The Royal Society.

Munificent Gift from Sir Alfred Yarrow.

THE generous gift from Sir Alfred Yarrow, announced in the subjoined letter from him to the president of the Royal Society, and gratefully accepted by the Society, is a most welcome acknowledgment from a great leader of industry of the practical service of scientific investigation. Sir Alfred, who was elected a fellow of the Society last year, has always taken an active interest in the progress of science and has promoted its application to industry in many ways—directly in his own works and indirectly by gifts to educational and scientific institutions. His faith in science as the maker of the modern world is unbounded, and the words in which he gives expression to it should afford scientific workers both pride and encouragement. We are at the beginning of a new era of human history, and it is to the close association of science and industry, in the spirit of Sir Alfred Yarrow's letter, that we must look for strength to meet the difficulties before us. The Royal Society, and the scientific workers it represents, may be trusted to continue to extend the boundaries of natural knowledge, and if statesmen and industrialists have the same progressive aims we can look with confidence to whatever the future may bring.

I would ask you to be so kind as to bring before the Council, at an early opportunity, the following proposals:

I have, for many years, held the view that the prosperity of this country has been greatly hampered in the past for the want of better promotion to scientific investigation and its application to practical affairs.

I am convinced that the future prosperity of this country will be largely dependent upon the encouragement of original scientific research. The birth of new industries, and the development of existing ones, are due largely to the growth of science, thus securing employment and the welfare of the whole community being advanced.

It is doubtful whether even yet it has been realised how completely this country would have been at the mercy of our antagonists in the late war, had it not been for the research work done by our scientific men before the war and during its course.

I desire to mark my sense of the value of research to the community by offering, as a gift to the Royal Society, 100,000*l.* to be used as capital or income for the purposes of the Society, as the Council may think fit, because I recognise conditions alter so materially from time to time that, in order to secure the greatest possible benefit from such a fund, it must be administered with unfettered discretion by the best people from time to time available.

Care must, of course, be taken that a gift from the fund shall in no case lessen any Government grant.

In accordance with your practice you would, I assume, appoint a Committee to administer the fund, and would also frame rules for the guidance of the Committee, while reserving the right to alter such rules from time to time; and I would suggest that they be reconsidered by the Council every tenth year so as to meet modern needs.

I should prefer that the money be used to aid scientific workers by adequate payment, and by the supply of apparatus or other facilities, rather than to erect costly buildings, because large sums of money are sometimes spent on buildings without adequate endowment, and the investigators are embarrassed by financial anxieties.

Although I thus give a general expression of my wishes, I do not intend, by so doing, to create any Trust or legal obligation for their fulfilment.

In conclusion, I should like to record my firm conviction that a patriotic citizen cannot give money, or leave it at his death, to better advantage than towards the development of science, upon which the industrial success of the country so largely depends.

A. F. Yarrow.

Obituary.

PROF. W. K. VON RÖNTGEN.

IT is given to few men of science to make a contribution to knowledge which compels world-wide interest from its first announcement. The late Prof. Röntgen's discovery of the X-rays in 1895 was not only of the first importance, but also enjoyed the distinction of finding an immediate and immense field of application in surgery and medicine. Presently they were destined to play also a prominent part in the extraordinary developments in atomic and molecular physics which have characterised the last twenty years—developments which make it safe to assert that at no period in its history has physical science been more effective and wide-reaching in its fundamental activities. Röntgen was happily spared to be a witness of all this, and although his contributions to X-ray research ceased some years ago, his satisfaction at the growth of the subject can have been in no way diminished.

Wilhelm Konrad von Röntgen was born at Lennep in the Rhineland on March 27, 1845. Although a German by birth, he was sent to school in Holland, and later he took his doctor's degree in Switzerland at Zurich in 1869. Then he was appointed assistant to Kundt at Würzburg in Bavaria, and afterwards at Strasbourg, where he carried out a well-known piece of work on the ratio of the specific heats of gases. He became a privat-dozent of the latter University in 1874. A brief period followed as professor of mathematics and physics at the Agricultural Academy at Hohenheim, after which he returned to Strasbourg in 1876 as extra-ordinary professor of physics. In 1879 he became professor of physics and director of the Physical Institute at Giessen; and six years later followed his appointment to the chair at Würzburg. It was here he made his famous discovery. Afterwards he was appointed to the chair of experimental physics and director of the Physical Institute at Munich; he resigned these appointments in 1919. Röntgen died at Munich on February 10, 1923, at the ripe age of seventy-eight years. He received the Nobel Prize for physics in 1901, and with Prof. Lenard the Rumford medal of the Royal Society in 1896.

While Röntgen's researches extended over a fair range of physics, their importance is completely overshadowed by his discovery of the X-rays, the credit for which is in no way lessened, but rather is enhanced by the curious belatedness of the event. Crookes, during his memorable investigations (1879–85), constructed a discharge tube with a concave cathode and a platinum target to display the heating effects of focussed cathode rays. Thus all the essential features of a modern gas X-ray tube were there, and X-rays must have been generated in abundance, but, although much of value *within* the tube was noted and recorded, the X-rays remained unnoticed.

Later Lenard, in 1894, demonstrated conclusively that cathode rays could pass through a thin window of aluminium, and were able to excite phosphorescence a few millimetres away in air. This was a correct observation, despite the fact that we now know that part of the phosphorescence was due to X-rays excited by the aluminium. About this time the inexplicable fogging of unopened packets of photographic plates in the neighbourhood of excited Crookes tubes was engaging the attention of more than one English physicist, but not until the autumn of the following year was the major discovery made by Röntgen, the manner of it being somewhat accidental. It so happened that in a search for invisible light rays he had enclosed a discharge tube in light-proof paper, and, to his surprise, noticed that, when the tube was excited, a barium platinocyanide screen lying on a table a few metres distant shone out brightly. If obstacles were interposed between the tube and the screen they cast shadows, and very quickly a unique and fascinating feature was revealed—the new or "X"-rays could penetrate many substances quite opaque to light. The degree of penetration depended on the density; for example, bone was more absorbent than flesh. When Röntgen communicated his results to the Physico-Medical Society of Würzburg in November 1895, the immense significance of his discovery received universal appreciation. A translation of his paper appeared in the issue of NATURE for January 23, 1896 (vol. 53, p. 274).

An army of workers sprang up and a torrential output of observations and speculation followed, as a glance at the scientific journals of those days will verify. The Röntgen Society came into being in London in 1897, largely at the instance of the late Silvanus Thompson, and similar societies were inaugurated later in other countries. Röntgen himself contributed three memoirs to the subject during these years, but later returned to his earlier interests in physics. He had, with others, established the fact of the ionising properties of the X-rays.

Much controversy and a wealth of speculation followed as to the nature of the rays. But experiment gradually whittled down the various theories, and no question now arises that the X-rays are light rays with wave-lengths which place them next to, and beyond, the ultra-violet. It was their minuteness of wave-length that defeated all the earlier attempts to sort out the rays, and this uncertainty continued until Nature herself was found to have fashioned suitable diffraction gratings in the form of crystals, the regular atomic spacings in which were of the right order of magnitude. We can now claim a knowledge of the existence of more than thirteen octaves of X-rays. Of these, three octaves or so are used by the radiologist, these having wave-lengths of the order of 10^{-8} cm.

We can only refer briefly to the enormous application of the X-rays in medicine. It is probable that no more potent weapon has been put into the hands of the medical man. The late war brought this home in unexampled fashion, and while human endeavour reached its pinnacle in almost every phase of life, it is difficult to overestimate the services which Röntgen's discovery rendered to humanity. An extensive industry in X-ray equipment has sprung up in this country and abroad.

The new knowledge was not without its menace, as many of the pioneers discovered to their cost. Prolonged and frequent exposure was found to produce

a disastrous effect on human tissue. But the conditions of danger and the means of avoiding them were gradually ascertained, and recently, thanks to the recent work of the X-ray and Radium Protection Committee, under the chairmanship of Sir Humphry Rolleston, president of the Royal College of Physicians, the necessary precautions have been widely circulated. In the light of a fuller knowledge the destructive effect of the rays has been turned to account by taking advantage of their selective action when applied to superficial and deep-seated growths in the tissue.

The X-rays have also found extensive industrial application to detect flaws and impurities, and in many other directions.

As already mentioned, the X-rays have proved of the greatest importance in recent developments of fundamental physics. We owe to them Moseley's arrangement of the elements in the order of their atomic numbers, a quantity determined by the atomic nucleus. The wonderful results of Sir William Bragg and his son on crystalline structure rest wholly on X-ray measurements. Much of the work which under Sir J. J. Thomson and Sir Ernest Rutherford has made the Cavendish Laboratory world-famous has dealt with X-ray and kindred phenomena.

At the close of Röntgen's life, we may well pause to survey the goodly harvest that science has reaped from the event with which his name will be for ever associated. Hard on the heels of his discovery came that of the electron by J. J. Thomson and of radioactivity by Becquerel. The new chapter of physics which was thus unfolded has already had the most profound effect on everyday life. G. W. C. K.

Mr. Bernard Bosanquet.

Mr. Bernard Bosanquet, who died on February 8, after a short illness at his home at Hampstead, to which he had moved a few months ago, has occupied for more than a generation a foremost place in English intellectual life. For the last ten years his health has required him to refuse public engagements, but he continued to be as assiduous in literary productions as during any period of his active life. He was at work till the end, and we are told that he left an uncompleted book on his desk, of which, however, three chapters are finished. The intended title was "What is Mind?" He was an ardent philosopher, who cared little for the brilliance of a speculation and nothing whatever for originality or ownership of ideas, but sought the truth concerning human life and the meaning of experience with an earnestness which seemed like the devotion of a religious mission.

Born in 1848, Mr. Bosanquet was educated at Harrow and at Balliol College, Oxford, and after graduating spent ten years at Oxford as fellow and tutor of University College. In 1881 he came to London and threw himself ardently into the work of the Charity Organisation Society and the Ethical Society, and also lectured on ancient and modern philosophy for the University Extension centres in London.

His "Logic, or Morphology of Knowledge" is a classic. It was published in 1888, and carried out with systematic thoroughness the new principle of an inner activity of thought which had already found expression in Mr. F. H. Bradley's polemic against the formalism and associationism of the empirical school. The next large work was "A History of Æsthetic" in 1892. In 1912–1913 were published the two volumes of Gifford Lectures, the first on "The Principle of Individuality and Value," the second on "The Value and Destiny of the Individual." It was in these lectures that he worked out his philosophical theory of the meaning of life. "This universe," he said, borrowing a phrase from Keats, "is the vale of soul-making." These volumes constitute one of the profoundest works of pure philosophy of the modern period.

Mr. Bosanquet was a man of great personal charm. Dialectic, in the Socratic meaning, was the joy of life to him, but he was always sympathetic to the opposer, genuinely eager to understand his point of view, and always anxious to appreciate its value. Yet no one was firmer or more tenacious in argument. He never expounded any theory or defended any position unless his whole heart was in it, and unless he was convinced of its truth.

Mr. Bosanquet kept himself fully abreast of all the intellectual movements of his time. He was thoroughly acquainted with the philosophical thought of Germany, and he was deeply interested in the new movement in Italian philosophy, the idealisms of Croce and Gentile, though dissenting from them on essential points. His knowledge of Italian was thorough, and only a few months ago he contributed an article in Italian to Prof. Gentile's *Giornale critico*. He was not attracted by the modern French philosophy, which he could never come to regard as other than superficial. The reason for this, no doubt, was that the approach to philosophy through the problems of science, the fundamental questions of mathematics, physics and physiology, which is especially distinctive of French philosophy, seemed to him less important and less compelling than the ethical approach.

Besides the important works mentioned, Mr. Bosanquet wrote numerous smaller books, many of striking originality and value; of these we may mention "The Philosophical Theory of the State" and two quite recent books, "The Meeting of Extremes in Contemporary Philosophy," 1921, and "Implication and Linear Inference," 1920.

For five years, 1903–1908, Mr. Bosanquet was professor of moral philosophy at St. Andrews. He was an original fellow of the British Academy, and was president of the Aristotelian Society from 1894 to 1898. He received the honorary degree of LL.D. from the University of Glasgow, and of D.C.L. from the University of Durham.

Mr Bosanquet married, in 1895, Miss Helen Dendy, a sister of Prof. Arthur Dendy, of King's College, London. Mrs. Bosanquet served on the Royal Commission of Inquiry into the Poor Law. She is the translator of Sigwart's "Logic" and the author of several books on social and economical questions.

Dr. A. H. Fison.

The staff of Guy's had subscribed money for a wireless installation to illustrate Dr. Alfred Henry Fison's lectures, and for the use of the hospital in other ways. On February 1, when on the roof by himself, attaching

an aerial, Dr. Fison fell through a skylight to the floor below. Three days later he died without regaining consciousness.

Dr. Fison's life-story is that of a teacher whose enjoyment in knowing was so vivid that no delight could equal that of passing his knowledge on. In his earlier life he had for twenty years lectured for the Oxford University Extension Delegacy; and this is a school in which the spirit of enthusiasm for knowledge is engendered. If an extension lecturer be not in complete sympathy with his audience, if he has not the instinct for detecting want of harmony between his mind and theirs, his lectures are a failure; his thought-waves must be of the length for which his auditors' receivers are tuned.

From 1912 until his death Dr. Fison was Secretary to the Gilchrist Trust. Each year in the spring he visited various parts of Britain to inspire enthusiasm and to organise local arrangements; in the autumn and winter to deliver lectures. His efforts to fill successfully the gaps caused by death in the Gilchrist staff discovered to him how very rare are the men who have the gift which he possessed of securing in their first few sentences the complete confidence of their audiences and retaining their strained attention for eighty or ninety minutes—halls crammed with people of all sorts and conditions, from the clergy, doctors, and schoolmasters of the town to miners and mill-hands—sending them away with the feeling that the evening which had closed a long day's work had altered their views of the world and had, at the same time, entertained them hugely.

In 1906 Dr. Fison was appointed lecturer in physics to Guy's Hospital, and somewhat later to the London Hospital also. Although his teaching work was elementary, he held that no teacher can be efficient who does not follow the most recent developments of his subject. He was a sound scholar—in the sense in which the expression is used by students of the humanities who are disposed to arrogate it to themselves. The very large gathering of students at the memorial service in the Chapel of Guy's was a measure of his success. Shortly before the accident brought his activities to a sudden close he talked to the writer of these notes of his plans for an early retirement and the devotion of his remaining days to investigations for which his duties as a teacher had left him but scanty leisure, and the publication of his reflections—his bent was ever towards philosophy—upon various aspects presented by the problems of physical science. His best-known contributions are "Recent Advances in Astronomy" (1898) and "A Textbook of Practical Physics" (1911, rewritten 1922).

Mr. Rawdon Levett.

THE death at Colwyn Bay on February 1 of Mr. Rawdon Levett, at seventy-eight years of age, will be regretted by none more than by the members of the Mathematical Association, of which, under its old name of the Association for the Improvement of Geometrical Teaching, he was one of the original founders. From his pen, in NATURE, of December 29, 1870, p. 169, first came the suggestion that such an Association should be formed, and the first conference was held at University College, London, on January 17, 1871. Levett possessed much more than the driving power and organising capacity which made him so successful a secretary in the first twelve years of the Association. Unlike most of his contemporaries he had familiarised himself with the continental text-books and with the methodology of his subject as taught in France, Germany, and Italy. The ideas of non-Euclidean geometry found in him an apt exponent to any who cared in those days to listen to him, and in the revolution that was to come in the fields of geometry and analysis he played for a time a prominent part. His "Elements of Trigonometry," which he brought out in collaboration with Dr. Davison in 1892, shows how much he had been influenced by De Morgan, by Cauchy and the continental school, and by Chrystal—and in that case the influence had been reciprocal.

The name of Canon J. M. Wilson has stood for half a century with that of Rawdon Levett on the list of officers or of vice-presidents of their Association. Both were at St. John's; Wilson was Senior in 1859; Levett was 11th Wrangler in 1865 (Rayleigh's year). Both were schoolmasters, Wilson in those days at Rugby, and Levett at King Edward's School, Birmingham. Both have retained their interest in the work of the Association, though ill-health had for many years past prevented Levett from taking any active part in its later history. The interests of neither were restricted to the sphere in which their academic honours were won.

Levett was a man of wide reading and general culture. By many his name was probably seen for the first time on the dedicatory page of "John Inglesant"—"I dedicate this volume to you that I may have an opportunity of calling myself your friend." The spiritual kinship that knit together men like Levett and Shorthouse indicates but one of the intellectual influences that brought to the Birmingham schoolmaster intimate relations with a wide circle of men who appreciated to the full his noble character, rare judgment, and fine literary instinct. Birmingham was the poorer by his loss when the shadow of the White Scourge fell upon him in 1903, and he retired to his Welsh home at Colwyn Bay. Now he is gone, and the only founders left are Canon Wilson, Mr. A. A. Bourne, Sir Thomas Muir, the Rev. E. F. M. MacCarthy (secretary for seven years), and the Rev. W. H. Laverty. W. J. G.

Prof. Gaston Bonnier.

WE regret to announce the recent death at Paris of Prof. Gaston Bonnier, professor of botany at the Sorbonne, member of the Institute (Académie des Sciences), of the Academy of Agriculture and the Council of the University of Paris, Officier de la Légion d'Honneur, foreign member of the Linnæan Society of London, and member of many other scientific bodies.

Prof. Bonnier was the president of the Société Botanique de France, and editor of the *Revue générale de Botanique*, founded by him in 1889. Among his numerous botanical publications that have become classic may be particularly mentioned his "Cours de botanique," "Géographie botanique et la botanique descriptive," "Flore complète de la France," "Nouvelle Flore des environs de Paris," and "Flore du nord

de la France et de la Belgique." His published research on the correlation of function, form and structure of plant organs is as remarkable for its simplicity and clearness of style as for its scientific value. His journalistic contributions to *Le Temps* were appreciated by all its readers.

Prof. Bonnier played a most important part in the reform and extension of the teaching of the natural sciences in France. To his students and research workers, including men and women of many nationalities, he was friend, guide and master.

The French president, the University of Paris, and many scientific bodies were represented at the obsequies, which took place with military honours.

Current Topics and Events.

ON February 14, Mr. Fisher presented to the House of Commons the usual petition from the Trustees of the British Museum praying for further support. Though this is merely a form arising out of the peculiar mode of government of the museum, we may be permitted on this occasion to emphasise the desirability of doing nothing that should hinder the performance of this trust " for the general benefit of learning and useful knowledge." The British Museum, a term which includes the Natural History Departments, is not one of those Government establishments that swelled its ranks and its expenses under stress of war, nor has it shown a reluctance to reduce them in the difficult times of peace. On the contrary, it has only just brought its scientific staff back to the pre-war level, and it has conscientiously reduced its estimates as required by the Geddes Commission. Its scientific publication is almost, if not entirely, suspended. This is a state of affairs we may lament, but must endure. What we are not prepared to suffer without protest is any further demand for reduction. There are rumours of such a demand, amounting to several thousands of pounds. This could only result in a diminution of the valuable work accomplished by this great establishment, work already most seriously hampered by the inadequate size of the staff. To choke one of the great founts of " learning and useful knowledge " can never be an economical proceeding, and any attempt to do so will meet with the united protest of all scientific workers.

THE Home Secretary has appointed a committee to inquire into the desirability of extending the Workmen's Compensation (Silicosis) Act of 1918, which provides compensation for men injured by silica in specified industries. The association of miner's phthisis (fibrosis of the lungs with superadded tuberculosis) with the inhalation of hard dust, as in quartz mining or knife grinding, has long been known, and its recognition has led to the introduction of appropriate preventive measures. Collis pointed out that the danger of a dust was in proportion to its content of free silica, and Mavrogordato found that coal dust was actually an antidote when mixed with rock dust, which by itself was highly injurious. Later experiments by Gye and Kettle have shown that the action of silica is chemical rather than mechanical, and that colloidal silica is distinctly poisonous. Chronic silica poisoning in rabbits causes degenerative changes in the liver and kidneys, and, though the applicability of these results to the occurrence of similar lesions in men is at present quite an open question, it is evident that the harmful effects of this common substance may prove to be much more widespread than is at present supposed.

THE New York correspondent of the *Times*, in the issue of February 13, refers to some successful experiments upon the dissipation of clouds by the Army Air Service of the United States at Dayton, Ohio, under the direction of Prof. Bancroft of Cornell University and Mr. Francis Warren. The process consists in scattering electrified sand with the propeller of an aeroplane moving 500 ft. above the tops of clouds. The sand is said to be charged to 10,000 volts, and the result is referred to in the headline of the note as " rain-making." The coalescence of the cloud particles in consequence of the diminution of surface-tension is suggested as the proximate cause of the disappearance of the clouds, which are stated to have varied from several thousand feet to several miles in length and breadth, and in thickness from 500 ft. to 1500 ft. The general conclusion of the correspondent is that fogs " need be no more and, given only clouds, rain can be had wherever it is wanted." An important question is, of course, how much ? " The time required to precipitate the moisture . . . rarely exceeded ten minutes," and in the case of very thin clouds the moisture evaporated before reaching the ground. Further particulars will be awaited with interest. In the meantime the announcement brings once more into prominence the need for special laboratories for the practical physics of the atmosphere, for which a good deal of work has long been waiting. The coalescence of water-drops, the correlative pulverisation of water and their relation to electrification, are not by any means fully explored. The energy-relations are very complicated. It is known, for example, that a bucketful of water tossed out of an aeroplane would be pulverised into an electrified cloud by its own gravitational energy. To get it back again into a continuous mass of water at the ground by the use of electrified sand will be a very interesting completion of the cycle when we understand it.

A TELEGRAM recently received at the Linnean Society from Tiflis announced that an eminent foreign member of the Society, Prof. Serge Gabrilovitch Navashin, of the Botanic Garden, Tiflis, Georgia, was to celebrate on February 18 his fortieth year of scientific work and the twenty-fifth anniversary of his announcement of double fertilisation in plants. This message recalls the new era in the study of the embryogeny of the flowering plants which followed

Treub's discovery of chalazogamy in Casuarina in 1891. Two years later Navashin reported a similar unusual course of the pollen-tube in the birch, and his own work and that of others supplied new instances. In 1898 Navashin announced at the meeting of the Russian Society of Naturalists his discovery, in species of Lilium and Fritillaria, of what at once became known as "double fertilisation"—the fact that, of the two male nuclei which enter the embryo-sac, one fuses with the egg-cell, the joint product being the embryo, while the other fuses with the two polar nuclei of the embryo-sac, either before or after their union, the product of this fusion being the endosperm, which supplies a store of nourishment in the seed for the embryo. The discovery was rapidly confirmed and extended by Navashin and others, and the occurrence was shown to be frequent if not general in the flowering plants. It gave a new interest to the discussion as to the true nature of endosperm, and, incidentally, provided an explanation of "xenia," or the occurrence outside the embryo of characters derived from the male parent. Notable contributions to this discussion were made by Strasburger, Miss Sargent, and others, but the problem still awaits a satisfactory solution.

THE Right Hon. T. R. Ferens, High Steward of Hull, has consented to accept the office of president of the thirty-fourth congress of the Royal Sanitary Institute, to be held at Hull on July 30–August 4.

SIR CHARLES PARSONS, honorary member of the Institution of Electrical Engineers, has been awarded the Faraday medal of the Institution. The medal is awarded for "notable scientific or industrial achievement in Electrical Engineering, or for conspicuous service rendered to the advancement of electrical science."

IN the *Observer* for February 18 it is recorded that "A Lahore telegram says that a meteorite, which was clearly seen in January in most of northern India, was traced at Quetta, where it buried itself. The remains show that at the time of impact it must have weighed six tons."

IT has now been announced that the donor of 5000*l.* to the Rowett Animal Nutrition Research Institute at Aberdeen is Mr. Walter Reid of Aberdeen. Other recent contributions include one of 500*l.* from the Highland Agricultural Society of Scotland.

WE learn from the *Scientific Monthly* that Dr. Robert A. Millikan, of the California Institute of Technology, Pasadena, has been awarded the 1922 Edison medal of the American Institute of Electrical Engineers for "meritorious experimental achievement in electrical science."

THE committee for the jubilee of Prof. Kamerlingh Onnes on November 11 last, which issued the memorial volume of the Physical Laboratory at Leyden, 1904–1922, announces that a limited number of copies of the volume is still available; copies may be obtained at the price of ten florins on application to the treasurer of the committee, Dr. H. R. Woltjer, Natuurkundig Laboratorium, Leyden, Holland.

ON Tuesday, February 27, at 3 o'clock, Sir Arthur E. Shipley will deliver the first of two lectures at the Royal Institution on life and its rhythms, and on Thursday, March 1, Mr. Theodore Stevens will begin a course of two lectures on water power of the Empire. The Friday evening discourse on March 2 will be delivered by Dr. G. C. Simpson on the water in the atmosphere, and on March 9 by Dr. C. W. Saleeby on sunlight and disease.

BY arrangement with the grand committee of the Royal Institute of British Architects in charge of the bicentenary celebrations of Sir Christopher Wren, Messrs. Hodder and Stoughton will issue on February 26 a memorial volume, dealing with various aspects of Sir Christopher Wren's life and work, under the general editorship of Mr. Rudolf Dircks, librarian of the Royal Institute of British Architects. The volume is being published at five guineas and upwards, and all the profits from its sale will be handed over to the St. Paul's Cathedral Preservation Fund.

AN exhibit of special interest at the present time will be found in Museum No. I. at Kew Gardens, in Case 128 on the ground floor. It consists of a collection of funeral wreaths, garlands, flowers, leaves, fruits, seeds, etc., in excellent preservation from ancient Egyptian tombs, including those of Aahmes I. and Rameses II., kings of Egypt of dates respectively 1700 B.C. and 11–1200 B.C. The flowers chiefly used are those of *Nymphæa cærulea*, *Acacia arabica*, var. *nilotica*, together with leaves of *Mimusops Schimperi* and *Salix Safsaf*. It may be noted that the various flowers, seeds, etc., are identical with those of the same species found growing at the present day.

AT the annual general meeting of the Society of Public Analysts held on February 7, the following officers and council were elected for the ensuing year:—*President*: P. A. Ellis Richards. *Past-Presidents*: Leonard Archbutt, A. Chaston Chapman, Bernard Dyer, Otto Hehner, S. Rideal, A. Smetham, E. W. Voelcker, and J. Augustus Voelcker. *Vice-Presidents*: F. W. F. Arnaud, F. H. Carr, and G. W. Monier-Williams. *Hon. Treasurer*: Edward Hinks. *Hon. Secretary*: E. Richards Bolton. *Assistant Hon. Secretary*: R. G. Pelly. *Other Members of Council*: H. Ballantyne, S. F. Burford, S. Elliott, B. S. Evans, E. M. Hawkins, Harri Heap, H. F. E. Hulton, Andrew More, A. E. Parkes, W. R. Schoeller, G. R. Thompson, and J. F. Tocher.

THE following officers and other members of Council of the Royal Meteorological Society were elected at the annual general meeting on January 17:—*President*: Dr. C. Chree. *Vice-Presidents*: Mr. R. H. Hooker, Dr. A. Crichton Mitchell, Dr. G. C. Simpson, Dr. G. T. Walker. *Treasurer*: Mr. W. Vaux Graham. *Secretaries*: Mr. J. S. Dines, Mr. L. F. Richardson, Mr. G. Thomson. *Foreign Secretary*: Mr. R. G. K. Lempfert. *Councillors*: Mr. C. E. P. Brooks, Dr. John Brownlee, Mr. David Brunt, Capt. C. J. P. Cave, Mr. J. E. Clark, Mr. R. Corless, Mr. F. Druce, Col. H. G. Lyons, Mr. H. Mellish, Sir Napier Shaw,

and Mr. F. J. W. Whipple. *Assistant Secretary*: Mr. A. Hampton Brown, 49 Cromwell Road, South Kensington, S.W.7.

THE Journal of the Camera Club, which first appeared in 1886 and was issued at regular intervals for twenty years, was one of the foremost of publications connected with photography. The authorities of the Club feel that the time is now ripe to begin a new series. It has been decided to issue the Journal quarterly, and that it shall contain summaries of lectures given before the Club as well as articles on photographic subjects. The first number has just been published, and contains among its many items technical articles by Dr. Alexander Scott, Mr. Chapman Jones, and others. The whole number is interesting, even to non-members of the Club, to whom its price is 6*d*.

THE Ministry of Agriculture is able to announce, as the result of conferences held at Washington in May and October last, that bulbs of Chionodoxa, Galanthus, Scilla, *Fritillaria imperialis*, *F. Meleagris*, Muscari, Ixia and Eranthis, have been added to the list of bulbs permitted unlimited entry into the United States, the permission holding good for a period of three years from January 1 last. The activities of the phytopathological service of the various countries at the ports continue to increase; bulbs now reach this country from Holland guaranteed by the inspection services of the Netherland Government. British potatoes may receive certificate of immunity after trial at the official station of the Ministry of Agriculture and Fisheries at Ormskirk, and the British phytopathological services receive increasing demands for inspection service before export. In the present state of our knowledge of plant pathology the requirements of these services raise many problems requiring further research; thus it is very difficult to say in the case of transplanted stocks, whether a swollen structure at the base is a somewhat excessive callus or a form of crown gall. Such questions seem to indicate the advisability of leisurely inspection at the nursery before despatch rather than examination at the port just before shipping. This plan is largely adopted, and recalls to mind the advantages and disadvantages of the Central Passport or Permit Offices which dealt with civilian travellers during the war.

THE eighth Bulletin of the Non-Ferrous Metals Research Association contains much valuable material. Good progress is being made with the systematic researches undertaken on behalf of the Association, and an extensive investigation is now planned, dealing with the subject of die-casting alloys. The scale of this investigation, which is of interest to the electrical as well as to the engineering industries, will depend on the amount of support received from firms making use of die-casting in some form. It is proposed to undertake work in three sections, dealing respectively with aluminium alloys, brass and bronze alloys, and alloys of low melting-point, the laboratories selected being the National Physical Laboratory, the Research Department of Woolwich, and the University of Sheffield. A new feature of the Bulletin is an article by Prof. Courtman on recrystallisation, with a bibliography of 73 items. Such summaries of published work are likely to prove valuable to members. Abstracts of important papers are also included, but in view of the extensive abstracting of the Institute of Metals it is intended to confine this part of the work to a small number of papers of special technical importance. The Association has adopted a very liberal policy in regard to publication.

Modern Wireless is a new magazine which promises to play an important part in popularising the art of radio communication, and guiding the development of methods of broadcasting. The first number, which was published in February, begins an interesting series of articles by Sir Oliver Lodge describing the method of transmission of wireless waves. There is also an important article by P. R. Coursey describing methods of receiving radio signals from electric lighting wires. It is not generally known that in many cases an aerial is an unnecessary adjunct to a broadcast receiving set. All that is necessary is to connect the set through a plug and a small condenser to any electric light fitting indoors. If a gas pipe or a water pipe is available we can use it for the earth, but in many cases, as Mr. Coursey points out, even this is not necessary. All that is required is to have access to the electric lighting wires whether the supply be direct or alternating. As an aerial is objectionable for several reasons, this method will help to popularise broadcasting, but it will make it difficult for the Post Office to enforce the purchase of a broadcasting license. There are many other interesting articles in this number. We congratulate the editor, Mr. J. Scott-Taggart, who is a well-known radio expert, on his success in making this issue interesting and easily understood, and yet maintaining high technical accuracy.

THE recent issue of the index parts of *Science Abstracts* completes Volume 25 of each of the sections —Physics and Electrical Engineering—for 1922. While the Electrical Engineering volume has nearly the same number of pages, 650, as last year, the Physics volume has increased by 90 pages, and now has nearly 1000 pages. The number of abstracts has increased by about 50 in the former and about 460 in the latter section, and there is a slight reduction in the average length, 0.486 page, of an abstract in the former and a considerable reduction, from 0.398 to 0.364 page, in the latter section. Ten years ago the figure was 0.317 page, and it is extremely doubtful whether the intrinsic value of scientific papers has increased in the interval to a sufficient extent to justify the increased length of the average abstract. Whatever opinion may be held on this question, there can be no doubt that *Science Abstracts* fulfils with conspicuous success its task of placing before its readers a short account of the advances made during the year in the subjects with which it deals, and that as a result it should receive every support from electrical engineers and physicists.

Research Items.

MENTAL AND PHYSICAL CHARACTERS IN RACE STUDY.—In the February issue of *Discovery*, Prof. H. J. Fleure discusses the influence of racial on mental characters. This region is, as he remarks, still uncharted by science, and the discussion is difficult because the material still remains to be collected. But racial peculiarities are strangely persistent, as, for example, in Wales, where the predominant type is in all probability due to descent, with modification, from the early Neolithic inhabitants, though it has been modified by emigration. At any rate, he rightly protests against the too common habit of treating mental characters, be it of French, Germans, or Britons, in the mass. "In each national group are many racial mosaics, and similar groups of characters occur in all. There are differences of social expression and lack of expression connected with social and historical facts, and these are apt to vary from century to century." But behind all these there are correlations of physical characters with psychical characters which at present we are unable to correlate scientifically.

THE FUTURE OF ARCHITECTURE.—In a recent issue of the *Sociological Review* (vol. xv. No. 1), Mr. S. C. Ramsey discusses the regional and vocational influences of architecture. The finest and most consistent architecture the world has ever seen was, he says, that of the ancient Greek quarryman. We can scarcely follow the writer in supporting the position that the sailor has been "the energiser and inspirer" of our buildings, nor in the assertion that "Victorian civilisation was essentially a miner's civilisation, the improvisation of the mining camp, and Victorian building was mainly of the camp or settlement variety, temporary and muddled, without real tradition, permanence, or ordered beauty." He sees hope in the houses erected under the Ministry of Health, where "mounting prices and the need for rigid economy have lopped off the extraneous and hideous features beloved of the Speculative Builder." He looks forward to the time when the person who expresses his individual pride in the building of a luxurious private house will not exactly be shunned, "but looked on a little critically," and "energy will be lavished on public buildings for the enjoyment and benefit of the community as a whole." It may be some time before this stage is reached, but meanwhile the writer's view of the position cannot safely be ignored.

CRIME AND POISONING.—Lt.-Col. J. A. Black, Chemical Examiner for the Punjab, has issued a report on the work of his department (Lahore: *Civil and Military Gazette* Press, 1921). The greater part of the report deals with matters involving the investigation of crime and especially of poisoning. Instead of expert witnesses being examined and cross-examined in a trial for poisoning as in England, the evidence of the Chemical Examiner is taken in Indian Courts, frequently in the form of a written statement. His report, therefore, contains a categorical account of the results of his analysis without indulging in probabilities or opinions, and leaving deductions, unless these are obvious, to the interpretation of the civil surgeon, whose duty it is to guide the Court. The Court does not appear to be otherwise guided in respect of matters purely chemical. The volume of work in connexion with cases of poisoning is considerable in the East, where homicidal poisoning is very prevalent, and suicidal poisoning, often from motives which appear perfectly inadequate to the Western mind, is very common. The difficulties are increased by the fact that cases of serious illness, and even of death, frequently occur without the attendance of qualified medical men, and the replies made by the police on the prescribed forms are frequently of little value. Col. Black enlivens his report by the narration of several picturesque cases which have come under his notice. The task is rendered somewhat easier by reason of the fact that the poisons available are mostly well-known, and on account of ignorance of the fatal dose, a large excess is usually administered, so helping to simplify the work of the chemist. For some of the poisons, when no chemical test is available, the microscopic appearance of the plant used is frequently quite diagnostic. Simple physiological tests are frequently made, and facilities have been afforded by setting up in Calcutta a laboratory for applying serological tests for the whole of India. Col. Black is of the opinion that no very subtle form of poisoning exists in India.

CHAPARRAL SCRUB IN CALIFORNIA.—The broad sclerophyll vegetation of California forms the subject of a communication by W. S. Cooper (Carn. Inst. Wash. Pub., No. 319) in which the ecological relationships of these types of vegetation are treated in some detail. The author is able to justify and develop the point of view of Schimper, that these types of vegetation, like the Mediterranean "maqui," develop in regions of winter rains and long dry summers. Thus the annual cycle of the "chaparral" scrub in California includes a summer period of four months in which the soil contains practically no available water, while the winter rains coincide with low temperatures. The growing period is thus limited chiefly to short periods in spring and autumn. Two main types of vegetation are compared in detail, the broad sclerophyll forest and the "chaparral," and it is shown that the habitat of the latter differs mainly in its more extreme water relations. Anatomical details of the plants in relation to habitat are well treated, a curious feature being the presence of mycorhiza in the roots of the dominant chaparral species, although the soils only average 0·1-0·3 per cent. of humus.

MITES AND ROTIFERS FROM SPITSBERGEN.—The Journal of the Quekett Microscopical Club, November 1922, contains an account by Mr. Julian Huxley of the Oxford University Expedition to Spitsbergen in 1921, followed by two reports on the collections of mites and rotifers. The aim of this expedition was primarily the study of Arctic life from an ecological standpoint rather than the search for new species, and the results promise to be of great general interest, especially from a biological point of view. Many new forms have, however, been discovered in addition to numerous new records for Spitsbergen, and as the work proceeds the number will be considerably increased. In the report on the mites, Mr. Soar describes and figures a species of Hydracarina, *Sperchon linearis* Sig Thor, taken in large numbers at Bear Island, hitherto known only from the high mountain districts of Norway and Sweden. He suggests that its appearance in Spitsbergen may be due to the agency of birds; the ova of the mites, which are deposited on stones, being probably conveyed there on the feet of birds. Mr. Bryce in his report makes similar suggestions for the occurrence of the rotifers—the agency of birds or transport by winds. He gives a valuable summary and revision of all the Rotifera found up to the present in Spitsbergen. The total number of species is now 81, of which 70 are actually more or less common in Great Britain. Twenty-eight species were taken by the

expedition, of which ten are new records, one being also new to science, but even this species shows no striking variation from already known European varieties. A list is given of mosses identified by Mr. H. N. Dixon, with their localities and details of the rotifers and tardigrades they harboured. The new species of rotifer and a new parasite are described and figured.

FUMAROLES IN ALASKA.—A volcanic eruption on a great scale in June 1912 smothered in half a foot of ashes the town of Kodiak in southern Alaska. This was traced to the Katmai volcano about 100 miles to the west in the long Aleutian chain of volcanoes. In 1915 the U.S. National Geographic Society sent a preliminary expedition to examine the region. The next year a larger expedition discovered to the west of Mount Katmai the remarkable valley of the Ten Thousand Smokes which was explored in 1917, 1918, and especially 1919. These explorations were conducted by Dr. R. F. Griggs, who describes them in "The Valley of Ten Thousand Smokes" (National Geographic Society, Washington). The valley, which has an area of about 30 to 40 square miles, is floored with Jurassic sandstones and shales overlain in places by volcanic rocks. Lines of fumaroles skirt the sides and cross the valley to the number of 10,000 or more. The fumaroles generally have a temperature of 200° C. to 300° C., but some records of over 500° C. are given. Analyses of the gases showed steam to be the principal constituent, but appreciable quantities of hydrofluoric acid were present. From earlier accounts of the district it is clear that these volcanic manifestations in the valley date from the eruption of Katmai in 1912. The text is admirably illustrated by photographs, maps, and coloured plates, and gives a full account of the valley and the work of the expeditions. It is written in a popular vein but embodies a great deal of scientific interest. The study of the vegetation in relation to the ash deposits is of particular value. The valley with Mount Katmai and the surrounding country, to the extent of 1700 square miles, has been declared by the United States Government a "National Monument" reserved from settlement or exploitation.

BACTERIA AND TRAVERTINE.—An interesting case of the promotion of rapid deposition of travertine by bacterial action has been described at some length by Mr. John Parry in a lecture given before the Diamond Fields Mining Institute at Kimberley, S. Africa (Report in *Chemical News*, vol. 125, pp. 225, 241, and 257, 1922). The organisms, which are compared in their action with Drew's marine *Bacillus calcis*, occur in water streaming down the shafts of Kimberley mines, and they produce deposits of fibrous calcium carbonate in iron pipes and crusts on planks and tunnel-floors. These deposits have a lustrous black surface, which is attributed to organic matter derived from decaying timber in the mines. Evaporation clearly plays no part in the accumulation.

THE UPPER AIR IN INDIA.—A presidential address by Mr. J. H. Field to the section of physics and mathematics of the eighth Indian Science Congress on "The upper air: objects and methods of research in India," is printed in the Proceedings of the Asiatic Society of Bengal, vol. xvii., 1921, No. 4. The subject of the address was chosen as the science of meteorology has during recent years attracted to its side physicists and mathematicians of eminence who are rapidly evolving order out of chaos. In contrast to the temperature changes experienced at the ground by day and night during summer and winter, it was pointed out that at the height of half a kilometre (1640 ft.) India enjoys an equable temperature throughout the twenty-four hours. Similarly with wind, both in direction and force, great changes very commonly occur within the lowest layer. Passing upwards through a range of many kilometres, the temperature, which has been falling more or less steadily to very low values, shows a sharp halt in its rate of fall, or the "lapse-rate" suddenly becomes zero. This startling change occurs in India at a height of about 10 kilometres; near the equator it lies at about 17 kilometres, and from the equator it falls continuously with increasing latitude toward the poles, where it seems to lie at a height of about 7 kilometres. Reference is made to observations of the upper air carried out in India by means of free-flying balloons and the theodolite and by means of balloons and kites carrying self-recording meteorological instruments; many clever devices have been introduced to adapt the observations to Indian climate. The solution of rainfall problems in India is alluded to as a matter of life and death, controlling as it does the dread spectre of famine. It is the business of the Indian meteorologist to forecast with all possible speed the rains both in the monsoon and in the cold weather.

THE GREEN RAY.—Instructor Lieut.-Commr. F. W. Shurlock, R.N., of H.M.S. *Royal Sovereign*, sends the following notes describing observations of the green ray: At Vigo, on January 21 and 22, the sun set behind an island. On January 21 one tip of the disappearing segment showed the green tint, while the other was indistinct, probably owing to irregular refraction. On January 23 the disc was red and changed to magenta. At sea, off Oporto on January 24, the two tips were green. The green portion broke up into irregular patches with colours resembling those of soap films. Just after sunset a row of irregular yellow patches appeared over the place where the sun's rim was last seen. At sea, off Cape St. Vincent on January 25, the sky being clear and the sun a golden yellow, a typical example was observed. The green colour started from the tips and flooded the exposed part of the disc. After sunset, a small diffuse patch of pale green appeared immediately above the place where the sun set and faded almost at once. The whole effect lasted about three seconds and was seen by a group of trustworthy observers. It is interesting to note that with a telescope (×30) the green afterglow was distinctly seen; with binoculars (×6) it was faintly seen; while unaided observers failed to detect it.

AN IMPROVED HYGROSCOPE.—Messrs. Negretti and Zambra have devised an improved hygroscope which indicates at a glance the percentage of moisture in the air. The hair hygrometer was originally constructed by Saussure, who used a hair to indicate changes of moisture, the hair elongating when moist and contracting when dry. Considerable improvements have been made by Messrs. Negretti and Zambra, and twelve or more hairs form the basis of the new instrument; human hair is specially selected and scientifically treated. The hairs are anchored by their lower ends and the upper ends are connected to a link which operates on a lever attached to the pointer spindle. The dial is graduated from 10 to 100 in percentage relative humidity. Readjustment of the instrument, if required, is quite simple. On the lower part of the dial is a scale to ascertain the dew-point if required. It is claimed that the instrument will be of especial value in many industrial processes, and various types are manufactured depending on the requisite conditions. A large type of the same instrument combined with a dew-point hygrometer has also been devised.

Comparative Embryology of Plants.[1]

IT is generally acknowledged that land-living plants have sprung from some algal source: that the land was invaded and that the invaders show form and structure adapted to sub-aerial life. If this be true, land-plants should still show features indicating their origin, and such characters should be expected to appear in their embryology. The higher algal structure is generally referable to the filament or row of cells with a free apex, and a base attached to the substratum. The individual commonly springs from such a source, amplified in various ways to form the adult. It is found that the comparative embryology of land-plants up to the seed plants themselves also suggest a filamentous origin. The apex is defined by the very first segmentation of the zygote: the base in bryophytes is the base of the sporogonium: in leafy plants it is the suspensor, recognised by Lang as a vestigial organ. He held that its presence is a last indication of the filamentous structure, a juvenile stage rapidly passed over in them, and often suppressed. The body thus visualised between apex and base may be called the primitive spindle.

Two distinct types of its orientation exist. In the first, the apex is directed to the neck of the archegonium (exoscopic). That is the characteristic of all bryophytes, and of Equisetum, Isoetes, and Tmesipteris. In the other, the apex is directed away from the neck (endoscopic), and it is found in lycopods, some primitive ferns, and in all seed-plants. An intermediate position is seen in certain ferns, including all the later types. In fact, with some exceptions, the distinction follows the major lines of affinity in the vegetable kingdom: therefore it is probably of high morphological importance. The interest will centre round the exceptions: and their explanation is probably to be found in the varying orientation of the archegonium.

The end of all higher embryology is the establishment of a leafy plant with its shoot pointed upwards. Where the archegonium points downwards, endoscopic orientation will lead directly to this result, but if the archegonium be inclined or inverted, the spindle will have to be inconveniently curved to secure that end. Many lycopods, selaginellas, and some ferns show awkward curvatures of the embryo to carry it out. But some of them have no suspensor: in these the awkward curves are absent. It is suggested that the inconvenience has been removed by abortion of the vestigial suspensor, which tied their ancestors down to the endoscopic orientation so inconvenient where the archegonium points obliquely, or actually upwards. The horsetails, Isoetes, and the leptosporangiate ferns would all be derivative in this respect. Having no suspensors, their initial polarity could be freely determined so that the apex would point from the first in the convenient direction.

Upon the spindle thus defined, whether complete or abbreviated by abortion, straight or curved, the appendages are attached. The leaves are possibly in phyletic origin, the results of distal dichotomy of the apex. But in fact they are attached laterally, and together with the axis they constitute the terminal bud. The first root is always of lateral origin in pteridophytes, and phyletically it is an accessory organ, absent in fact in the most primitive types. It is only in seed-plants that it appears to continue the axis downwards. Lastly, the "foot," which is so inconstant in its development, is clearly accessory also, in fact a sucker formed laterally where it is required. So the primitive spindle, defined by the apex of the shoot and with the tip of the suspensor as its base, appears to be a real and constant feature in the embryos of plants. But as it is liable to be abbreviated by the abortion of its base, and complicated at the apex and also lower down by the formation of lateral appendages of various sorts, it is often effectively disguised. Nevertheless, an adequate morphological and biological comparison of plants suggests that all their embryos are referable in origin to a filamentous source, such as is prefigured in the algæ.

[1] Abstract of the presidential address to the Royal Society of Edinburgh, delivered by Prof. F. O. Bower, F.R.S., on October 23, entitled "The Primitive Spindle as a Fundamental Feature in the Embryology of Plants" (Proc. Roy. Soc. Edin., vol. xliii. part i. p. 1).

Exploitation of South African Fisheries.[1]

By Prof. J. STANLEY GARDINER, F.R.S.

THE Union of South Africa has consistently endeavoured to pursue a far-sighted policy in reference to the exploitation of its seas. A survey with the S.S. *Pieter Faure* was made twenty years ago and resulted in the starting of a trawler industry, while a series of volumes were published dealing with the fauna of the grounds. In 1920 the Union hired a whaler, the *Pickle*, 102 feet long; 20 feet beam, and 11½ feet draught, equipped the vessel with trawls, warps, and sounding gear, and sent it to explore the fishing area, Dr. Gilchrist being the scientific adviser. The ship was commissioned for 20 months. It was singularly unsuited in many respects for trawling in commercial fashion, being of too shallow draught and not of the right build, only hauling an otter trawl of 40 feet head rope, whereas a trawler of its size could employ one of 120 feet with resulting catch at least six times as great. Notwithstanding these drawbacks excellent work was done, 543 stations having been investigated, generally by 1-hour trawls, distance traversed 4 miles. While the hauls are thus closely comparable, they are difficult to collate with commercial fishing. They deal entirely with unexplored grounds; we should have liked a few on the known grounds, already frequented by steam trawlers, for comparison.

Commercial trawling is now carried on down to 300 fathoms, and the total area within these depths off South Africa is about 120,000 square miles. The grounds may be divided into three areas—the eastern off the shores from Kosi River to Port Elizabeth, 625 miles; the southern from the latter to the Cape, 360 miles; and the western from the Cape to Cunina River, 1080 miles. The eastern is mostly a 10-mile belt, sloping off steeply from 60 fathoms; this is the region of the Agulhas Current, which causes in most places a roughness unsuited to trawling. The southern is that of the Agulhas Bank, a name given to the southern broad point of the continental slopes, its edge 150 miles from the shore. The western has a broad slope, not bounded by any marked steep, about 60 miles across, half within the 100-fathom line; it is on the whole smooth and regular ground, and lying on the colder side of the Cape—average difference 10° F.—should prove good trawling ground with fish of similar quality to those of our own shores.

The two most important deeper water fish proved to be the stockfish, or Cape hake, and Macrurus,

[1] Union of South Africa: Fisheries and Marine Biological Survey. Reports Nos. 1 and 2 for the years 1920 and 1921. By Dr. J. D. F. Gilchrist.

or Cape whiting, both of which have their centres of intensity at 150 fathoms, or even deeper. There is also the kingklip (in appearance like a ling), the dogfish, various soles and other flatfish, but the variety of economically valuable trawl fish so far obtained is not great. New fishing areas were discovered off Durban and off the Umvoti River, but neither of these are of sufficient size for steam trawlers. However, crayfish up to 12 inches occurred in immense numbers, a commercial trawler subsequently, in a haul of 1½ hours, taking more than 10,000. The results of the investigation indicate an abundance of life on all this eastern ground, and it must carry its due proportion of fish. Many small areas suitable for trawling appear likely to be disclosed by further survey, but it is not an area for steam trawlers, though, like the west coast of France, it should develop in time a considerable population of "long-shore" men.

Turning to the south and west the reports give indications here of the possible development of an immense fishery. The *Pickle* demonstrated to the local trawlers the potentialities of deep-sea fishing, and new areas were found within a few hours' steaming of Cape Town. The most northerly trawlings were off Luderitz Bay, and it would seem probable that there is good ground right down to Cape Town; we should also expect similar ground further north as far as Union territory extends. Before such ground can be exploited commercially it must be surveyed, so that trawlers may avoid rough patches. To know the depth and nature of the bottom is not enough, and trawling tests are essential. Doubtless the fish migrate at different seasons, so that the latter tests will have to be undertaken at least twice over. It is an expensive business, of course—the running expenses of a trawler would be about 1000*l.* per month—but the encouragement of food production is a vital necessity to all States, while fish-meal is a bye-product of high value. In any event it is clear that South Africa has to the south and west an area more than capable of supplying all the fish that can at present be consumed; the western grounds alone may well prove as rich as those to the south of Ireland of about the same area, which in 1910 produced 1·35 million cwts.

With these potentialities in mind it is extraordinary to find that the fishery vessel is to be given up. In substitution a survey vessel, *Crozier*, is to be used at intervals for fisheries work. To employ a twin-screw vessel with a complement of 80 hands for such work is wretched economy, work which can be better done with a trawler and a crew of 14. The phase of using such Admiralty vessels for fishery work is one which nearly every country of Western Europe has passed through and abandoned; surely South Africa would be well advised to learn by their experiences. In any event we trust that the series of special reports on the fauna obtained by the *Pickle*, commenced in report 2, will be proceeded with; they are of high scientific value.

The Teaching of Elementary Geometry.[1]

THE Assistant Masters' Association recently appointed a committee to consider the teaching of elementary geometry; the report of this committee, backed by the authority of the Executive Committee of the Association itself, that of the Assistant Mistresses' Association, and that of the Educational Institute of Scotland, has now been published. The outstanding fact, and one of no little importance, is that the committee was appointed to produce an agreed sequence of propositions and has not done so. The terms of reference were:

(*a*) To examine the case for an agreed sequence;

(*b*) To suggest the best means of attaining the general adoption of the sequence agreed upon.

The most definite conclusions are:

VII. The committee does not feel that it is either desirable or possible at present to stereotype a sequence; and

I. No formal proofs should be required of Euclid I. 13, 14, 15, 4, 8, 26, 27, 28, 29. . . . The teaching of formal geometry should be based upon the quasi-axiomatic acceptance of these results.

The committee is unquestionably right in its belief "that the main difficulties due to variety of sequence will be removed if the first of its recommendations [*i.e.* I. just quoted] is generally accepted," and possibly the most valuable feature of the report is the extended currency it will give to this principle.

For the rest, the committee is concerned not so much with principles as with giving what help it can to the "very large number of teachers who do not claim to be experts in geometry" and who need "guidance amid the welter of sequences and methods . . . published during the last twenty years." From this modest and reasonable point of view little fault will be found with the detailed recommendations, though, as is freely admitted, there is room for difference of opinion on many points. A teacher who followed their scheme exactly would come to no harm.

The committee follows in the main the "Cambridge Schedule," with some expansions (which some will not think improvements) apparently designed to show exactly how it intends the propositions to be dealt with. For example, the section on areas begins with the rule for measuring the area of a rectangle and the section is more detailed than in the Schedule, clearly indicating a treatment different from Euclid's. It is pointed out at the end of Section VI. that Pythagoras's proposition and Euclid III. 35, 36 should be dealt with by the use of similarity as well as by Euclid's method. The report contains a needed warning (Recommendation IV.) against the slovenly use of the "method of limits" in dealing with tangency; and another (Recommendation V.) against ignoring the existence of incommensurables; "at the proper stage," the committee says, "the attention of the pupil should be called to the fact that the proofs given do not cover all cases."

A very important feature of the report is that certain propositions are marked with an asterisk, indicating that formal proofs of them should not be required in examinations. Some are marked also with a (†), indicating that no formal proof should be attempted in the class-room.

On this point the practice of Examining Bodies differs; most of them asterisk propositions, but some more, some less. It would undoubtedly be of great assistance to the schools if uniformity could be reached, and for this purpose the selection made by the committee might well be taken as the standard.

Altogether, the committee may be congratulated on its work; it has not set up obstacles to further progress, as with its terms of reference it easily might have done; on the other hand, the report will probably reach many teachers who need help and will give them much of the assistance they need.

Photograph of a Bright Meteor.

CONSIDERING the great frequency of the appearance of bright meteors which flash across the night sky, it is astonishing how few photographs of them have been obtained. The actual photographing of a meteor is really quite a simple matter, but the whole success of the operation depends on whether the camera is pointed to the position in the sky where a meteor happens to pass.

FIG. 1.—Photograph of a Taurid fire-ball.

While any camera will serve the purpose, a suitable instrument is one having a large aperture and short focal length. In a communication to the Royal Astronomical Society (Monthly Notices, vol. 83, p. 92) Dr. W. J. S. Lockyer describes a very interesting photograph which he has secured, and also the instrument used. The lens is an old portrait doublet having an aperture of five and a quarter inches and a focal length of twenty-eight inches; quite a suitable lens. This lens is mounted in a home-made box camera which carries a plate 8½ × 6½ in. The field of the lens covers about 16 degrees.

For the purpose of photographing meteor trails, the camera is fixed firmly on a stand and pointed directly at the pole star. This direction is chosen because the stars make their trails completely on the photographic plate, these trails being portions of small circles. By comparing such trails with a star atlas all the stars can be easily identified and the position of the meteor trail accurately deduced. It is Dr. Lockyer's usual practice, when working at night with the 9-inch prismatic camera of the Norman Lockyer Observatory, always to expose as long as possible one plate in this meteor camera, which is erected just outside the dome.

During the night of November 16 last, the plate (Marion's "Record," H.D. 500) was exposed from $8^h\ 58^m$ to $11^h\ 12^m$ G.M.T. In the course of development the first images to appear were the trail of the pole star and a long streak across the plate which was the trail of a bright meteor. A reproduction of a portion of this plate (reduced by one-quarter) is shown in Fig. 1. The photograph shows practically the complete length of the meteor trail.

Considering the slowness of the movement of the image of the pole star (the short brightest trail near the pole) due to the earth's rotation, and the relatively great speed of the meteor—probably in any portion of its trail only a very small fraction of a second—the brilliancy of the latter must have been very great, judging by the great density of the trail.

The most striking feature of the meteor's trail is the great differences in intensity along its path. In some portions it is so bright that it has produced halation on the photographic plate (unbacked) as strong, if not stronger, than the pole star itself. These intensity differences are due most probably to the unequal volatilisation of the material forming the meteor.

It is interesting to note that the meteor trail, when traced on a celestial globe, passes close to a star named κ Tauri, the radiant point, for that date, of slow-moving bright meteors, as determined by Mr. W. F. Denning. Evidently the meteor here photographed was a Taurid fire-ball and the brilliancy of its image was due to its comparatively slow motion.

An Australasian Biological Collecting Expedition.

THE native animals and plants of Australia are of exceptional interest, and many of them are likely to disappear, or at least to become rare, as the result of the extension of the settled areas of the country—a process which has already been in operation for many years. The Trustees of the British Museum, recognising the importance of securing an adequate representation of this remarkable fauna and flora while there is yet time, have made arrangements for a collecting expedition, which started from London a few days ago. Mr. G. H. Wilkins, to whom the leadership has been entrusted, has special qualifications for carrying out his task with success. He is Australian by birth, and he has a good knowledge of the country, where he has many friends from whom he may expect to receive valuable assistance. He has travelled extensively in various parts of the world, and he has already acted as naturalist to several important expeditions. He spent four years, 1913–1917, on the coast of Alaska and in the Beaufort Sea, as a member of the Stefánsson Canadian Arctic Expedition. In 1920 he visited Graham Land with the Cope Expedition, and in 1921–22 he was with the Shackleton-Rowett Expedition, in the *Quest*, visiting South Georgia and the Antarctic Quadrant from Enderby Land to Coats Land. On the return journey valuable collections were made at Gough Island.

Mr. Wilkins expects to be able to obtain assistance, partly voluntary, in Australia, and thus to be provided with a scientific staff among whom the various branches of the work will be distributed. A special effort will be made to obtain good series of mammals, birds, insects, and other members of the land fauna, and to spare some time for the collection of plants. He will collect first in Queensland, at one or two selected stations, going south when the rainy season commences, revisiting Queensland in 1924, and reaching the Cape York Peninsula in one or both years.

A preliminary survey, on a smaller scale, by a collector employed by the Godman Exploration Fund Trustees, has shown that the representation of Australian mammals in the national collection is by no means so complete as it should be; and there is good reason to believe that the projected expedition will add considerably to existing knowledge. This preliminary work has been rendered possible by a generous gift made by Dame Alice Godman and her

daughters, in memory of the late Mr. F. du Cane Godman, a trustee of the British Museum. The fund thus created will enable the Museum to do much useful work of a similar character, and its utility would be greatly increased if it were to be augmented by the contributions of other benefactors. It is not sufficiently realised that the work of the Museum is hampered in many directions by the want of funds which would perhaps be supplied from private sources if its needs were more generally known.

University and Educational Intelligence.

ABERDEEN.—Mr. W. W. M'Clelland, additional lecturer on education, has been appointed principal lecturer on education in the Edinburgh Training Centre.

The statutory meeting of the council of the Association of University Teachers of Scotland was held in Aberdeen on Saturday, February 10. Prof. F. O. Bower was appointed chairman of the council for the ensuing year, and Dr. W. W. Taylor, honorary secretary.

BRISTOL.—The following appointments have been made at the Agricultural and Horticultural Station at Long Ashton: Mr. H. Briton-Jones, as lecturer in mycology; Mr. Edward Ballard, as adviser in plant pathology, and Mr. H. P. Hutchinson, as organiser of research in willow growing.

Arrangements are being made for holding a summer school on August 3-17. Prof. Lloyd Morgan will again be president of the school, and Mr. W. W. Jervis will act as director of studies.

Geography will, in future, be included as a subject for the final part of the curriculum for the degree of B.Sc.

CAMBRIDGE.—Mr. G. E. Briggs, St. John's College, has been re-appointed demonstrator in plant physiology.

A further report of the Syndicate appointed to draft Ordinances to carry out the new statute for the admission of women to degrees has just been issued. In one very important point the report has now been modified; the women students are to be given the right to admission to University instruction effectively on the same terms as members of the University. It looks as though one chapter in this long-standing controversy is drawing to a close.

Revised regulations for the medical examination have been submitted to the Senate for approval. The transference of organic chemistry from the First M.B. examination to the Second M.B. examination will facilitate the process by which the First M.B. examination is passing from the University to the schools.

EDINBURGH.—The University Court has accepted with much gratitude a gift by Mr. James A. Hood, of Midfield, Lasswade, of the sum of 15,000*l.* to endow a chair of mining. It is proposed that the chair should be established by the University and the Heriot-Watt College in co-operation.

The following appointments have been made: in the faculty of science, Dr. Malcolm Wilson to be reader in mycology and bacteriology, and Dr. H. Robinson reader in experimental physics; in the faculty of arts, Dr. G. A. Carse to be reader in natural philosophy.

The Cameron prize in the faculty of medicine, which is given annually in recognition of some important and valuable addition to practical therapeutics, has been awarded for 1923 to Prof. J. J. R. Macleod, of the University of Toronto.

LONDON.—A course of three free public lectures on "Recent Work on Inborn Errors of Metabolism" will be given by Sir Archibald E. Garrod, in the Robert Barnes Hall of the Royal Society of Medicine, at 5.30, on Wednesdays, February 28, March 7 and 14.

OXFORD.—On February 13, Congregation had before it a proposal to establish a new final school in science and philosophy. The scheme was introduced by Prof. C. J. Webb and Mr. H. B. Hartley, and supported by Profs. H. H. Joachim and J. L. Myers. It was opposed by the Warden of Wadham and Mr. H. W. B. Joseph, and thrown out on a division by 66 to 38. Many will regret that an opportunity for bringing scientific and philosophical studies into closer relation has thus been lost. The arguments of the opposition that carried most weight were probably those that were concerned with matters of practical difficulty rather than of principle.

The reports of the Delegates for Forestry and of the Committee for Rural Economy were presented to Convocation on February 20. The former report gives the number of students at the beginning of the year as 76. Lectures were delivered on silviculture, general and tropical, forest management, mensuration, protection, policy, valuation, utilisation, botany, entomology, surveying, and engineering, by Prof. Troup, Sir William Schlich, and others. Parties of students were taken for practical instruction to France, Austria, and various stations in England. Full use was made of the practical training ground of Bagley Wood. The first of the Oxford Forestry Memoirs was issued during the year.

The Committee for Rural Economy reports the number of students of agriculture as 134. Lectures have been given by Prof. Somerville and others. The University farm has been largely used for practical demonstrations, and other farms have been visited and important papers have been published. A special study of farm management has been conducted under the auspices of the Institute for Research in Agricultural Economics. A research on soils is in progress by Mr. G. R. Clarke.

Both of these departments show evidence of great activity and efficiency. They have come to take an important part in the present life of the University.

AN engineering scholarship, of the annual value of 70*l.*, tenable for three years, provided by the South Wales Institute of Engineers, is being offered for competition by the University College of South Wales and Monmouthshire. Further information, and the form of application, may be obtained from the Registrar, University College, Cardiff. Applications must be received by, at latest, March 19.

THE annual general meeting of the Association of Technical Institutions will be held at the Carpenters' Hall, Throgmorton Avenue, London, E.C., on Friday and Saturday, March 2 and 3. At the opening meeting the president, the Right Hon. Walter Runciman, will introduce the president-elect, Sir Alfred Herbert, who will deliver his presidential address. The following papers will be read on the Friday afternoon and Saturday morning: "Modern Systems of Apprenticeship and Training of Young Workmen with reference to Technical Education," Mr. W. Calderwood; "The Guilds of London and Technical Education," Mr. C. C. Hawkins; "The British Colour Industry—its Dependence on the Place of Research in the Scheme of Higher Education," Dr. H. H. Hodgson; "The Dyeing Industry, Research Work and Technical Education," Dr. Levinstein.

Societies and Academies.

LONDON.

Royal Society, February 15.—E. R. **Speyer**: Researches upon the Larch Chermes (*Cnaphalodes strobilobius*, Kalt.), and their bearing upon the evolution of the Chermesinæ in general. Alternation of form is the normal course of biological development in all Chermesinæ, but it breaks down in *Cnaphalopes strobilobius*, Kalt. The Progrediens type of all Chermesinæ is potentially a winged form, and is not a true dimorphism of the Sistens type. The Sexuales are different morphologically from all other generations and are probably a new production in evolution. Species which are purely parthenogenetic have ceased to develop from an evolutionary point of view, and show the probable course of evolution in the various genera. Migration from one species of conifer to another is responsible for a duplication in the series of form-alternating, parthenogenetic generations; the series upon one conifer has become morphologically different from that on the other through the action of Natural Selection in two different environments. In existing species with two host-plants, that portion of the cycle which now takes place upon the definitive host-plant has arisen through a stimulus given by a recent return to sexuality, this accounting for the linking up of the two cycles and a duplication of the series of parthenogenetic generations.—G. V. **Anrep**: The irradiation of conditioned reflexes. Experiments were performed with tactile conditioned reflexes, the parotid gland being taken as the effector organ. The tactile reflexes established on one side of the animal irradiate without a measurable decrement into the other side of the animal. The conditioned inhibition is in broad limits a cruder form of inhibition than the differential inhibition. The irradiation of the conditioned inhibition follows in the main the rules established for the irradiation of the differential inhibition and that of the reflex itself. The short trace reflexes take an intermediate position between the simultaneous and the long trace reflexes.—M. **Dixon** and H. E. **Tunnicliffe**: The oxidation of reduced glutathione and other sulphydryl compounds. The reduction of methylene blue by the sulphydryl compounds, reduced glutathione, cystein, and thioglycollic acid, is an autocatalytic reaction. The active agent producing this catalysis is the disulphide form R.S.S.R. The disulphide compounds also catalyse the oxidation of the sulphydryl compounds by atmospheric oxygen. The form of the reaction curves is not autocatalytic. The reaction velocity in the cases of glutathione and cystein shows a sharp optimum at a *p*H of 7·4. Thioglycollic acid does not show this. The bearing of these results on the conception of the function of glutathione and related compounds in tissue oxidation processes is discussed.—J. C. **Bramwell**, R. J. S. **McDowall**, and B. A. **McSwiney**: The variation of arterial elasticity with blood pressure in man. A method is described by which the extensibility of an artery in living man may be measured at all internal pressures up to the diastolic pressure. As in the case of an isolated artery, the extensibility decreases as the internal pressure is increased.—L. J. **Harris**: On the existence of an unidentified sulphur grouping in the protein molecule. Pt. I.—On the denaturation of proteins. Pt. II.—On the estimation of cystine in certain proteins. The conditions under which the grouping reactive to nitroprusside is liberated from ovalbumin and other proteins, and of its survival in the proteose, peptone, and polypeptide molecule, were examined. The nitroprusside reaction, attributed by Arnold to cystein, may be due to the presence of a grouping of the thiopeptide type. Gravimetric estimation of cystine in proteins by a new method indicates that whereas in serum albumen the cystine accounts for 89 per cent. of the total sulphur content, in ovalbumin 86 per cent. of the sulphur still remains to be accounted for.—N. B. **Laughton**: Reflex contractions of the cruralis muscle in the decerebrate and spinal frog. In the decerebrate frog there was a prolonged tonic after-effect in the contraction of the cruralis muscle on reflex stimulation of the ipsilateral sciatic nerve. No such tonic effect was observed in the cruralis muscle of the spinal preparation. A shorter latent period and a more rapid increment of height were marked in the spinal preparations. During spinal shock the height of the reflex contraction in the spinal frog is not maximal. In half the experiments the height of the myogram was greater in the decerebrate than in the spinal preparations.

British Mycological Society, January 20.—H. **Wormald**: Crown gall on nursery stock. Résumé of crown gall investigations and account of crown gall on apple stock in this country.—Miss W. **Ridler**: The fungus present in *Lunularia cruciata*. The fungus is not constant in occurrence, but when it occurs, it is definitely localised. There is no evidence that the fungus has any effect on the production of sexual reproductive organs or gemmæ or on the size of the plants. The association is regarded as harmless parasitism on the part of the fungus.—A. S. **Horne**: The systematic characters of closely allied strains of Fusarium were described. Spore shape, dimensions, and septations have proved exceedingly variable and of less relative value in classification than occurrence of sclerotia, chlamydospores, colouring principles, relation to active hydrogen, etc. "Sectoring" often occurs in culture and has resulted in increase in the number of strains from 6 to about 14.—W. **Brown**: Experiments on growth rate and cultural factors of the same species of Fusarium. The amount of "staling" varied in different strains. Practically any cultural characteristic can be developed in any one strain by choosing suitably the composition of the various constituents of a synthetic medium.—J. **Ramsbottom**: Berkeley and Broome: An account of the way in which these two mycologists became interested in the study of fungi and associated together, as shown by their correspondence in the British Museum (Natural History).

Geological Society, February 7.—Prof. A. C. Seward, president, in the chair.—G. Vibert **Douglas**: Geological results of the Shackleton-Rowett (*Quest*) expedition. The more detailed work commenced in South Georgia, which lies 900 miles east of Cape Horn and is 100 miles long by 20 miles in width. It is an upland dissected by glacial action. The glaciers in general show signs of withdrawal. The island consists of sedimentary rocks and, at the south-eastern end, igneous rocks. The sediments may represent two periods of deposition, divided by an unconformity. The rocks all show signs of metamorphism, and the strike of the folds and lamellæ of the phyllites indicate that the pressure came either from the south-south-west or from the north-north-east. Elephant Island is situated in the Powell group of the South Shetlands and is an ice-covered plateau rising to 1200-1500 feet above sea-level. The Tristan da Cunha Group, 1500 miles west of the Cape of Good Hope, are of volcanic origin. Gough Island, more than 200 miles south of the Tristan da Cunha Group, is 8 miles long by 3 miles

in width. It is a monoclinal block, with dip-slopes to the west and escarpments to the east. The lavas forming these features are basaltic, and intrusive into these lavas is a trachytic stock. Following this intrusion the basalts were cut by a series of dolcritic dykes. In general, it is similar to Ascension and St. Helena Islands.

DUBLIN.

Royal Dublin Society, January 23.—Prof. J. A. Scott in the chair.—J. **Joly**: Isostasy and continental drift.—H. H. **Dixon** and N. G. **Ball**: The structure of the vascular supply to the storage organs of some seedlings. According to the view that the tracheæ convey material only in an upward direction, and are not functional in the downward transport of organic substance in the plant, the organs connecting the stores of organic substances with embryos would either contain no tracheal (woody) strands, or would possess only vestigial traces of this tissue. In the seedlings of *Lodoicea sechellarum*, *Phœnix canariensis*, *P. dactylifera*, *P. silvestris*, and of *Vicia faba*, the petiole of the cotyledon transports the stored organic material to the growing embryo, and in the bundles the tracheal or woody strand is normally developed, and in some cases, at least, the tracheæ are differentiated earlier than the sieve-tubes. Hence the structure of these seedlings is in agreement with the view that the wood transmits organic materials.

PARIS.

Academy of Sciences, January 29.—M. Albin Haller in the chair.—Georges J. **Rémoundos**: The iteration of multiform functions.—A. **Angelesco**: A class of polynomials and an extension of Taylor's and Laurent's series.—E. **Gau**: The study of invariants relating to the characteristics of partial differential equations of the second order with two independent variables.—Birger **Meidell**: The probability of errors.—Paul **Piketty**: Cold hardening by drawing. The method of M. Seigle for increasing the strength of metal bars by extension up to the elastic limit was utilised by the author in 1911 for reducing the weight of steel in reinforced concrete construction.—Jean **Chazy**: The expression of Einstein's law in Cartesian co-ordinates.—MM. **Huguenard, Magnan**, and A. **Planiol**: A compensated hot wire anemometer. The most convenient way of mounting a hot wire anemometer is to measure the fall of potential over a resistance placed in the circuit containing the hot wire. The curve showing the gas velocity as a function of the potential differences is nearly parabolic, and as a consequence accurate measurements can be made only over a narrow field. If the shunt be replaced by a fine platinum wire of variable resistance, the conditions can be arranged to give a linear relation between the potential differences and the gas velocity.—Rodolphe **Soreau**: The laws of variation of the characteristics of standard air with altitude. A new formula is deduced for the pressure as a function of the altitude in which the temperature of the air is eliminated. The pressures calculated from the equation agree well with the experimental results, the latter being computed from 89 observations with balloons at heights ranging up to 20,000 metres.—L. **Décombe**: The theory of gravitation.—M. de **Broglie** and J. **Cabrera**: The gamma rays of the radium and thorium family studied by their photo-electric effect. The apparatus described in an earlier communication has been applied to determine the wave lengths of the gamma rays of the mesothorium group.—A. **Portevin** and P. **Chevenard**: The dilatometric study of the alloys of aluminium with magnesium and silicon. The coefficients of expansion of the alloys were obtained by a differential method against a standard of pure aluminium.—Mlle. G. **Marchal**: The dissociation of silver sulphate. The dissociation was studied over the temperature range 820° C.-1220° C., and the partial pressures of oxygen, sulphur dioxide, and sulphur trioxide calculated for 28 temperatures between these limits.—Paul **Mondain-Monval**: The law of solution. Sodium nitrate obeys the solubility law of Le Chatelier very closely.—Edouard and Remy **Urbain**: The atmolysis of a gaseous mixture containing several constituents. Application to the mixture utilised in the sulphuric acid industry by the contact method.—F. **Loewinson-Lessing**: A relation between the atomic numbers and atomic weights of the chemical elements. Starting with helium, for the first twenty elements the atomic weight is equal (within one unit) to the sum of the atomic number of the element and of that immediately succeeding it.—L. J. **Simon** and G. **Chavanne**: A new method of preparation of monochloracetic acid. The preparation is based on the hydration of trichlorethylene by sulphuric acid (90-93 per cent.) at a temperature of 170° C. The yield is more than 90 per cent. of the theoretical.—M. **Tiffeneau** and Mlle. J. **Lévy**: Pinacolic and semi-pinacolic transpositions. Comparison of the aptitude to migration of various radicals. In these transpositions the migrating tendency of the ethyl and benzyl groups is much more marked than with the methyl radical. No satisfactory explanation for this can be given.—A. **Briquet**: The invasion of the sea on the coast of Berck and the teachings of recent geology. The encroachments seriously threaten the Haut-Banc light and the City of Paris Hospital. The causes and possible engineering remedies are discussed.—F. **Raspal**: Temperature measurements in trial borings 1700 metres deep near Molières (Gard). At 1674 metres depth the temperature was 82°·5 C. A rise of 1° C. per 24·3 metres was found as an average over the range 300 metres to 1674 metres.—Pierre **Bonnet**: The existence of the upper Silurian and lower Devonian in southern Transcaucasia.—G. **Pontier**: The presence of *Elephas planifrons* in the red crag (English Upper Pliocene). An account of a detailed examination of a molar of *E. planifrons* found north of Felixstowe in 1922.—J. **Thoulet**: Relation between the depth of the line of appearance of mud and the depth of the waves.—Ph. **Wehrlé** and R. **Cordebas**: The notion of phase in the study of the undulatory perturbation of pressure.—Marcel **Mirande**: Special elaborating organites (sterinoplasts) of the epidermis in the scales of the bulb of the white lily.—Robert **Stumper**: New researches on the venom of ants. Determinations of the percentages of formic acid from three species of ants (*Cataglyphis bicolor*, *Camponotus æthiops*, and *Camponotus maculatus*). Formic acid was proved to be the only free volatile acid present.—E. **Aubel**: The microbial metabolism of lactic and pyruvic acids.—René **Legendre** and Maurice **Nicloux**: A mask designed for administering oxygen in artificial respiration. After poisoning by carbon monoxide or other gases, the efficiency of the usual methods of artificial respiration is much increased if oxygen is simultaneously administered. The mask described resembles those used in administering anæsthetics, and leaves the eyes uncovered. It is furnished with two valves and is of small capacity. Schafer's method of artificial respiration is recommended.—Georges **Mouriquand** and Paul **Michel**: The experimental conditions of the action of cod liver oil. Its osteodystrophic power in the presence of an insufficient food regime.

Diary of Societies.

SATURDAY, FEBRUARY 24.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (2).

BRITISH PSYCHOLOGICAL SOCIETY (at Bedford College), at 3.—Prof. T. H. Pear: An Examination of some Current Beliefs concerning Muscular Skill.—Miss M. MacFarlane: The Use of Mental Tests in American Schools and Clinics.

MONDAY, FEBRUARY 26.

VICTORIA INSTITUTE, at 4.30.—Dr. A. T. Schofield: The Voices behind Spiritism.

INSTITUTE OF ACTUARIES, at 5.—P. H. McCormack: Damaged Lives and Options.

FELLOWSHIP OF MEDICINE (at Royal Society of Medicine), at 5.30.—C. Rowntree: Cancer of the Breast.

INSTITUTION OF MECHANICAL ENGINEERS (London Graduates' Section), at 7.—Prof. E. G. Coker: Photo-Elastimetric Researches on Mechanical Engineering Problems.

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—Adjourned Discussion on: Dental Sepsis as an Œtiological Factor in Disease of other Organs.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Lt.-Col. T. T. Behrens: The Brenner Pass Boundary and Italy's New Province.

TUESDAY, FEBRUARY 27.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Arthur E. Shipley: Life and its Rhythms: (1) Life and its Attributes.

BRITISH SCIENCE GUILD (at Mansion House), at 3.30.—Sir Ronald Ross, Rt. Hon. Sir Joseph Cook, and others: The Importance of promoting Efficiency and Economy in Industry, Commerce and all Imperial Affairs by the Progressive Use of Science and Scientific Method.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. W. G. Savage: Canned Foods in Relation to Health (2).

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—Eng.-Comdr. R. Beeman: Auxillary Machinery.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—R. Chislett: Bird Life in the North Isles of Shetland.

CIRCLE OF SCIENTIFIC, TECHNICAL, AND TRADE JOURNALISTS (at Institute of Journalists).—J. L. Greaves: Paper: Some developments in its Manufacture.—Discussion on the Requirements of Art, Trade, Technical and other Journals.

WEDNESDAY, FEBRUARY 28.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—S. H. Warren: The Late Glacial Stage of the Lea Valley (Third Report). With a Report on the Arctic Flora by Mrs. Eleanor Mary Reid and Miss Marjorie Elizabeth Jane Chandler.—S. H. Warren, with Appendices by Dr. C. W. Andrews, Mrs. E. M. Reid, and Miss M. E. J. Chandler, A. S. Kennard, B. B. Woodward, and M. A. C. Hinton: The *Elej has-antiquus* Bed of Clacton-on-Sea (Essex), and its Flora and Fauna.

ROYAL MICROSCOPICAL SOCIETY (Industrial Applications of the Microscope Section), at 7.—Demonstrations and Exhibits.—C. Baker: The R.M.S. Microscope (New Model).—C. Beck: Mercury Globules under Polarised Light, with Special Reference to Dr. Owen's Communication read at the last Meeting.—A. Gallenkamp and Co., Ltd.: The Gallenkamp Electrometric Titration Apparatus, an "End Point" Indicator for all Acid, Alkali and Oxidation Titrations.—Adam Hilger, Ltd.: Interference Accessory for testing the Stands and Fine Adjustments of the Microscopes—Vertical Illuminator for the Microscopical Examination of Opaque Objects.—Ogilvy and Co.: Silverman Illuminator for Opaque Objects and Standard Illuminator, both showing Similar Specimens for Comparison of Image—W. Watson and Sons, Ltd.: A Petrological Binocular Microscope for Glass Examination, illustrated by Lantern Slides.—H. J. Denham: Some Mounting Media for Microscopic Objects, especially for Cotton and other Hairs and Fibres, and for general Microscopical Work.—T. Terrell, junr.: The Use of the Microscope in the Gas Mantle Industry.

ROYAL SOCIETY OF ARTS, at 8.—Prof. W. E. S. Turner: Heat Resisting Glasses.

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at Medical Society of London), at 8.30.—Dr. J. A. Hadfield: Some Observations and Criticisms of Psychotherapeutic Methods.

ROYAL SOCIETY OF MEDICINE (Social Evening), at 9.—Sir William Hale-White: Pasteur in Relation to Medicine.—Prof. T. M. Lowry: Pasteur in Relation to Chemistry.—Dr. G. Monod: Pasteur as an Artist.

THURSDAY, MARCH 1.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—T. Stevens: Water Power of the Empire (1).

INSTITUTE OF CHEMISTRY at 4.30.—Annual General Meeting.

ROYAL SOCIETY, at 4.30.—A. Mallock: The Effect of Temperature on some of the Properties of Steel.—Prof. C. H. Lees: Inductively Coupled Low Resistance Circuits.—Lord Rayleigh: Studies of Iridescent Colour, and the Structure producing it. I. The Colours of Potassium Chlorate Crystals. II. Mother of Pearl. III. The Colours of Labrador Felspar.—Dr. L. V. King: The Complex Anisotropic Molecule in Relation to the Dispersion and Scattering of Light.

ROYAL COLLEGE OF SURGEONS OF LONDON, at 5.—Dr. W. G. Savage: Canned Foods in relation to Health (3).

LINNEAN SOCIETY OF LONDON, at 5.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—Major F. M. Green: Helicopters.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Prof. L. Hill: The Sun and Open-Air School.

INSTITUTE OF ELECTRICAL ENGINEERS, at 6.—Report presented on behalf of the British Electrical Research Association by S. W. Melsom and E. Fawssett on Permissible Loading of British Standard Paper-insulated Electric Cables.

CHEMICAL SOCIETY, at 8.—N. V. Sidgwick: Co-ordination Compounds and the Bohr Atom.—W. H. Gray: Silver Salvarsan.—Prof. H. B. Dixon: On the Propagation of the Explosion-wave through Gaseous Mixtures.

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section), at 8.—S. Forsdike: The Treatment of Hæmorrhage at the Menopause by Radium, with a report upon 45 cases.

CAMERA CLUB, at 8.15.—G. B. Clifton: My Method of making Bromoil Prints.

FRIDAY, MARCH 2.

ASSOCIATION OF TECHNICAL INSTITUTIONS (Annual General Meeting) (at Carpenters' Hall), at 11 and 2.—Sir Alfred Herbert: Presidential Address.

EMPIRE FORESTRY ASSOCIATION (at Guildhall), at 3.—Annual Meeting.

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 4.45.—Dr. J. Horne: Tumours in the Inter-Arytenoid Space of the Larynx.

PHILOLOGICAL SOCIETY (at University College), at 5.30.—C. T. Onions: Dictionary Evening.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—C. Saxton: Glass-forming Machines.

BRITISH MEDICAL ASSOCIATION (Marylebone Division), (at Medical Society of London), at 8.—Dean Inge: Religion and Medical Sociology.

ROYAL SOCIETY OF MEDICINE (Anæsthetics), at 8.30.—Dr. W. G. M'Cardie: General Anæsthesia in ordinary Dental Surgery (to be followed by a discussion).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. G. C. Simpson: The Water in the Atmosphere.

SATURDAY, MARCH 3.

ASSOCIATION OF TECHNICAL INSTITUTIONS (Annual General Meeting) (at Carpenters' Hall), at 11 and 2.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (3).

PUBLIC LECTURES.

SATURDAY, FEBRUARY 24.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—S. H. Warren: The Interplay of Land and Sea.

TUESDAY, FEBRUARY 27.

LONDON SCHOOL OF ECONOMICS, at 5.—Sir Josiah Stamp: Statistics, before, during, and after the War: Income and Wages.

WEDNESDAY, FEBRUARY 28.

LONDON SCHOOL OF ECONOMICS, at 5.—Prof. Graham Wallas: The Competition of the Sexes for Employment (Stansfeld Lecture).

KING'S COLLEGE, at 5.30.—Principal L. P. Jacks: The Limitations of Natural Science.

ROYAL SOCIETY OF MEDICINE, at 5.30.—Sir Archibald E. Garrod: Recent Work on Inborn Errors of Metabolism. (Succeeding Lectures on March 7 and 14.)

THURSDAY, MARCH 1.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 5.—Sir Ryland Adkins: Architecture and the Countryside (a Layman's Question).

UNIVERSITY COLLEGE, at 5.30.—Prof. A. E. Richardson: The Public Buildings of Sir Christopher Wren.

FRIDAY, MARCH 2.

KING'S COLLEGE, at 5.30.—C. E. M. Joad: The Case for Pluralism (1). (Succeeding Lectures on March 9 and 16.)

SATURDAY, MARCH 3.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Legends of the Gods of Ancient Egypt.

NEGRETTI & ZAMBRA
38, HOLBORN VIADUCT, E.C.1.
LONDON.

UNIVERSITY OF LONDON.

A course of four lectures on "ELECTRIC FIELDS IN ATOMIC PHYSICS" will be given by Professor E. T. WHITTAKER, F.R.S. (Professor of Mathematics in the University of Edinburgh), at UNIVERSITY COLLEGE, LONDON (Gower Street, W.C.1), on MARCH 13, 15, 20, and 22, 1923, at 5.15 P.M. At the first lecture the Chair will be taken by Professor L. N. G. FILON, F.R.S. (Goldsmid Professor of Applied Mathematics and Mechanics in the University). ADMISSION FREE, WITHOUT TICKET. Syllabus on application to the undersigned.

EDWIN DELLER, Academic Registrar.

KEBLE COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIP, 1923.

An Examination will be held in this College on March 13 for two SCIENCE SCHOLARSHIPS of the annual value of £80, with laboratory fees £20.

Subjects: Chemistry *or* Biology, with elementary Physics, and for Biologists elementary Chemistry as well.

Intending candidates should apply to Dr. HATCHETT JACKSON, the Science Tutor, for information.

BEDFORD COLLEGE FOR WOMEN
(UNIVERSITY OF LONDON).
POST-GRADUATE SCHOLARSHIP IN SOCIOLOGY.

The Council of Bedford College for Women invite applications for the above scholarship. Value £150 for one year. Open to women only.

For further information apply THE SECRETARY, Bedford College, Regent's Park, N.W.1.

APPOINTMENTS BOARD
OF THE
IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,
SOUTH KENSINGTON, S.W.7.

EMPLOYERS requiring men who have received a thorough training in Science and Technology, and who are Diplomates or Associates of the Imperial College, or of one of its three constituent Colleges, are asked to make use of the services of the Board. No fees.

The Imperial College includes The Royal College of Science, The Royal School of Mines, and The City and Guilds (Engineering) College. The Associates of the Colleges receive thorough training in Science and Technology, including Aeronautics, Applied Optics and Optical Engineering, Biology, Chemical Technology, Chemistry (all branches), Engineering (all branches, including Metallurgy, Mining, Mining Geology and Oil Technology), Geology, Mathematics and Mechanics, and Physics.

BATTERSEA POLYTECHNIC.

Principal—* ROBERT H. PICKARD, D.Sc., F.R.S.

University Courses, day and evening, under Recognised Teachers of the University of London are provided in Science, Engineering and Music.

CHEMISTRY.—*J. KENYON, D.Sc., F.I.C.; *J. L. WHITE, D.Sc.

PHYSICS.—* S. MARSH, B.Sc., Ph.D.; * A. E. EVANS, B.Sc.

MATHEMATICS.—* F. M. SAXELBY, M.Sc., B.A.; * F. W. HARVEY, B.Sc., M.A.; * W. G. BICKLEY, M.Sc.

MECHANICAL AND CIVIL ENGINEERING.—* W. E. M. CURNOCK, M.Sc., B.Eng.; *J. B. SHAW, A.R.C.S., Wh.Ex.; * H. M. EDMONDS, B.Sc.; * V. C. DAVIES, B.Sc., A.M.I.Mech.E.; * H. L. DINGWALL, B.Sc.(Eng.); K. HAMILTON, B.Sc.(Eng.); A. WATSON, B.Sc.(Eng.).

ELECTRICAL ENGINEERING.—* A. T. DOVER, M.I.E.E., A.Am.I.E.E.; * H. C. MANN, A.M.I.E.E.; * H. W. HARTRIDGE, A.M.I.M.E.; * A. M. PARKINSON, B.Sc.(Eng.).

MUSIC.—* H. D. WETTON, Mus. Doc., F.R.C.O.

* Denotes recognised teacher of University of London.

There are also:—

Day Technical College in Engineering and Science. Day Training College of Domestic Science. Day Department of Hygiene and Physiology. Day School of Art and Crafts.

Evening Courses in Engineering, Chemistry, Physics, Mathematics, Bacteriology, Chemical Engineering, Hygiene and Physiology, Art, Matriculation Subjects, Domestic Economy, Music, Physical Training.

Hostels for Women Students. Large playing fields at Merton.

ST. SAVIOUR'S AND ST. OLAVE'S GRAMMAR SCHOOL FOR GIRLS,
NEW KENT ROAD, LONDON, S.E.1.

WANTED, for September, SCIENCE MISTRESS to take Zoology in Advanced Course and assist in Botany to Matriculation standard and in General Elementary Science in Middle School. Good degree and experience in teaching in Secondary School essential. Training preferred. Burnham Scale for London.—Apply to HEADMISTRESS.

CHELSEA POLYTECHNIC,
CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.** Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.** Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement, Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.** Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

SIDNEY SKINNER, M.A., Principal.

Telephone: Kensington 809.

BIRKBECK COLLEGE.
(UNIVERSITY OF LONDON.)

Principal—GEORGE SENTER, D.Sc., Ph.D., F.I.C.

EVENING COURSES for the Degrees of the University of London in the Faculty of Science and for the Geography Diploma.

Facilities are also provided during both day and evening for Post-Graduate and Research Work.

Calendar, 1s.; by post, 1s. 5d. Prospectus free.

For full particulars, apply to the SECRETARY, Birkbeck College, Fetter Lane, E.C.4.

LOWESTOFT SECONDARY SCHOOL.
APPOINTMENT OF HEADMASTER.

Applications are invited for the vacant post of HEADMASTER of the Lowestoft Secondary School. The successful candidate to take up duties on September 1, 1923.

The School is a day school of 430 boys and girls, governed by a Joint Committee appointed by the East Suffolk County Council and the Town Council of the Borough of Lowestoft, and is recognised by the Board of Education under the Secondary Schools Regulations. A copy of the Articles of Government can be obtained from the undersigned. Price sixpence.

Applicants must hold a *good Honours Degree* of a British University, and must not be over 45 years of age.

Salary £700 per annum.

Form of Application can be obtained on receipt of a stamped addressed Foolscap Envelope. Applications to be sent in to the undersigned on or before March 28, accompanied by copies of not more than three recent testimonials.

Canvassing members of the Joint Committee, either directly or indirectly, will disqualify candidates.

R. BEATTIE NICHOLSON, Town-Clerk, Lowestoft, and Secretary to the Joint Committee.

Education Offices, Town Hall, Lowestoft, February 21, 1923.

UNIVERSITY OF ST. ANDREWS.
CHAIR OF CHEMISTRY IN UNITED COLLEGE AND DIRECTORSHIP OF CHEMISTRY RESEARCH LABORATORY, ST. ANDREWS.

The University Court of the University of St. Andrews invite applications for the Vacant CHAIR OF CHEMISTRY in the United College of St. Salvator and St. Leonard, and for the Directorship of the Chemistry Research Laboratory at St. Andrews. The Professor to be appointed will enter upon his duties at October 1. Further particulars will be furnished by the undersigned, to whom applications, with at least three references, should be sent, not later than May 15.

ANDREW BENNETT, Secretary and Registrar.

The University, St. Andrews, February 1923.

EXCITING SEA EXPEDITION—Vacancies for scientific men. Capital essential. LEGION, 6 Adam Street, Adelphi, London, W.C.2.

X-RAY TUBE STAND FOR SALE—Also Casettes, Screen, etc. Write for list. Box No. 60, c/o NATURE Office.

NO. 2783, VOL. 111]

Sequence in School Geometry.

THERE is discontent as to the condition of geometry teaching in schools, and in the search for remedies the question has been reopened whether there should be an "agreed" sequence. It appears from the report summarised in NATURE of February 24, p. 271, that 90 per cent. of those members of the Assistant Masters' Association who replied to a questionnaire voted for such a sequence, but there is the significant note, "The figures cannot be more than approximately correct, as some of the replies were difficult to interpret." It may be worth while to consider the question itself: what is meant by a "sequence"; for, unless we are clear about this, the question is ambiguous, and discussion, to say nothing about voting, may be wide of the mark.

Fifty, forty, even thirty years ago the pathway through school (and even college) mathematics was beset with the notice "Verboten." A boy might not use algebra in doing arithmetic; analysis was forbidden in geometry papers; calculus in doing analytical geometry or mechanics; while to mention a sine or cosine in the natural philosophy paper of a certain examining body would have been to pull the very whiskers of death.

Such, at least, were the facts as understood by those still *in statu pupillari* and as impressed upon them by their immediate teachers, whatever liberty the higher powers—the examiners—may have exercised in practice. But, above all, there must be no departure from the order of Euclid, and to use a later proposition in the proof of an earlier was mortal sin.

Now, here a distinction should be made: in part Euclid's order is essential to his general argument; but in part it is not and is merely matter of chance or convenience. For example, I. 16 (that the exterior angle of a triangle is greater than either of the interior opposite angles) of necessity comes before I. 32 (that the exterior angle is equal to the two together); and to use the latter to prove the former is a real error, betraying want of grasp of Euclid's argument.

On the other hand, his Sixth Book (on proportion and similar figures) does not depend on any proposition subsequent to I. 36 and I. 38 (that parallelograms and triangles on equal bases and between the same parallels are equal). Consequently, to use VI. 8 to prove I. 47 would not have been false logic, or an essential departure from his system, but merely a variation from the particular method he chose to adopt.

By sequence, then, we may mean either essential sequence, departure from which destroys the validity of the argument, or merely the arrangement of the subject-matter in an order dictated by convenience

or taste, not by logic. Now, what is in the mind of those who desire a uniform sequence, whether agreed or imposed? We do not know; but it may be useful to consider the case for both kinds of sequence—that of logic and that of convenience. We will take the latter first.

It would, no doubt, be convenient, as boys frequently move from school to school, if all followed the same general order—taking, for example, the circle before similarity or vice versa. But agreement on an open question like this is unlikely, for each of the equally admissible orders would find strong advocates, and teachers keenly interested in their work would not willingly surrender their liberty.

The graver question, of course, is as to the logical sequence. But in fact, the current practice of schools has eliminated the question in this form; for the practice is now widespread (and the Assistant Masters' Association's Report will give it further currency) of beginning the formal study of geometry at a point where a sufficiently broad quasi-axiomatic basis has been established, namely, the conditions of congruency of triangles and the angle properties of parallel lines.

This means in effect the abandonment, or at least the postponement, of most of Euclid's propositions up to I. 32. Experience has shown that many of these individual propositions are not really grasped by the ordinary boy, and if these are omitted others become unnecessary, as they are mere links between the others. The advantage of the omission is that a boy can begin where the work is easy instead of where it is most difficult.

Two questions of great importance emerge, however, and it is probably to these that those who are, quite justly, dissatisfied with the present state of things should address themselves. First, how can we recover anything that we have lost by departure from the strict traditional system; and second, when, if at all, should boys be introduced to the initial difficulties which have been evaded?

As to the former, it is suggested that the proper guiding word is not "sequence," but "interconnexion"—that the idea required is not so much that of a single thread, as of a network of argument. It is an excellent practice to take a known proposition and trace its connexions backward. Thus the property of a cyclic quadrilateral depends on the relation between the angle at the centre and that at the circumference; this, again, depends on two early propositions, namely, the exterior angle of a triangle is equal to the two interior angles, and the angles at the base of an isosceles triangle are equal; the former depends on the angle properties of parallels, the latter on congruence. Following this process, wherever we begin, we always get back to one or both of these fundamental principles.

This illustration shows how grasp of sequence can be strengthened; as illustration of interconnexion take Pythagoras's proposition. It may be proved, as in Euclid, by use of parallelograms and congruent triangles; or by variants, using parallelograms only, which, however, depend on congruent triangles; but again it may be proved by the use of similar triangles (Euclid VI. 8). But similar triangles rest on the angle properties of parallels and on Euclid VI. 2, or the equivalent proposition as to the segments made on transversals by parallels, and this, again, depends on congruence. Similarly, it seems unwise to neglect either of the proofs of Euclid III. 35, 36 (rectangles contained by segments of chords); the proof by similarity is the easier and shows the inwardness of the proposition better; Euclid's proof brings out the important fact that the rectangle is equal to $k^2 - r^2$, the "power of the point." Illustrations might be multiplied; but these will suffice to indicate what is meant, the habit of tracing connexions which gives mastery of the whole, and, it may be added, greatly increased power in what, after all, is the essential thing, the art of doing riders.

The second question does not, perhaps, as yet admit of so definite an answer: when and how far should pupils be asked to face the initial difficulties—congruence, parallelism, and the link propositions (*e.g.* inequalities) necessary for dealing with them? A partial answer may be given with some confidence: not until they have mastered the rest of the work and have gained power in solving problems. Beyond this it is not safe to dogmatise, but if geometry is worth studying for its own sake, for its beauty and essential interest, and not merely as an exercise in logic, it is quite possible, and, indeed, for most boys probable, that they will gain more by going on—by studying the ordinary developments not contained in Euclid, *e.g.* coaxal circles, pole and polar, inversion, etc., and geometrical conics, to say nothing of solid geometry—than by going back to examine first principles. Still in sixth form work, possibly in favourable circumstances in a fifth form, time might well be found for this; properly handled it would arouse great interest and would certainly be well within the power of the boys—as it is not within that of a third form. It involves, above all, the parallels axiom and some consideration of the relationship between axioms and definitions; in fact, it is quite as much a philosophic as a mathematical question. Its treatment would be rendered more effective by some knowledge of non-Euclidean geometry on the part of the teacher.

The Development of the Quantum Theory.

(1) *Molecular Physics.* By Dr. James Arnold Crowther. (Text-books of Chemical Research and Engineering.) Third edition. Pp. viii+189. (London: J. and A. Churchill, 1923.) 7*s.* 6*d.* net.

(2) *The Quantum Theory.* By Prof. Fritz Reiche. Translated by Dr. H. S. Hatfield and Henry L. Brose. Pp. v+183. (London: Methuen and Co., Ltd., 1922.) 6*s.* net.

TO give an intelligible account of the modern theory of "quanta" is a difficult, if not an impossible, task. Many of the ideas involved are unfamiliar, and between them and the laws of orthodox physics lies an unbridged gulf. Our sympathy must therefore be extended to the authors of the two volumes under consideration in the attempts they have made to explain and elucidate the theory. Dr. Crowther has added an interesting chapter of an elementary character on quanta to his book on molecular physics, and although his treatment is, perhaps necessarily, somewhat didactic he has succeeded in bringing out clearly the difficulties to be faced and the method of meeting them. "The merit of Planck's theory is not so much that it removes our troubles altogether, but that it packs them all together into one bag, so to speak, so that they become easier to handle." Prof. Reiche has given an exceptionally lucid exposition of the origin and development of the quantum theory, and the translation of his book, which appears to have been carefully carried out, may be recommended to English-speaking students of the subject. It is to be regretted that the bad example of the German original has been followed in collecting together indiscriminately mathematical notes and references to the number of 325 in an appendix of more than fifty pages.

The birth of the quantum theory was December 14, 1900, when Dr. Max Planck, professor of theoretical physics in the University of Berlin, made a communication to the German Physical Society on the distribution of energy in the normal or "black body" spectrum. He described a new method of obtaining the formula (which he had announced a few weeks earlier), representing the way in which the energy is divided between the various frequencies which go to form the complete continuous spectrum of the radiation. In order to secure agreement with experimental results Planck was led to the hypothesis of energy quanta, according to which the radiation energy of any assigned frequency ν can be emitted and absorbed only as an integral multiple of an element of energy $\epsilon=h\nu$, where h is a constant of Nature, now known as Planck's constant. The numerical value first given by Planck was $h=6{\cdot}55\times10^{-27}$ erg. sec., a value which is in remarkably good agreement with later determinations by several widely different methods. The fundamental relation of Planck's theory may be written in the form $\epsilon/\nu=nh$, where n is a positive integer. Thus h is a quantity of the dimensions of energy multiplied by time, that is of "Action" as that term is used in connexion with the Principle of Least Action, and the universal constant h represents a true *atom* of Action. Jeans remarks that "an attempt to imagine a universe in which action is atomic leads the mind into a state of hopeless confusion." Perhaps the attempt would be less bewildering were it possible to visualise more clearly the four-dimensional space-time world of Minkowski, in which action rather than energy is conserved. An element of this world may be regarded as an element of action.

In dealing with the radiation problem an incandescent body may be pictured as containing a large number of small oscillators, or Hertzian resonators, which are capable of acquiring energy and emitting radiation. In the first form of Planck's theory the fundamental hypothesis was that each resonator can acquire or lose energy only by sudden jumps, in such a way that its store of energy must always be an integral multiple of the quantum $h\nu$. Thus a resonator of high frequency can avail itself of energy only in large units, while a resonator of low frequency can absorb or emit energy in small quantities. It is not difficult to see that consequently the radiation will contain comparatively little light either of very short or of very long wave-length. There must be some intermediate value of the frequency corresponding to *maximum* emission of radiation, as is actually found to be the case in experiments on the distribution of energy in the spectrum of a "black body." By combining this conception of energy elements with Boltzmann's definition of entropy, Planck arrived at his celebrated radiation formula, which is found to agree closely with the results of observation. To minimise the difficulties associated with the discontinuous emission and absorption of radiation, Planck put forward modified forms of his theory later on, but many writers, including Poincaré, prefer the more drastic treatment originally proposed.

The failure at low temperatures of the law of Dulong and Petit, which assigns a constant value to the product of atomic weight and specific heat of a solid, may be explained if we abandon here, as we have already done in dealing with radiation, the principle of the equipartition of energy and make use, in some form or other, of the idea of a quantum. Einstein in 1907 was the first to attempt to solve this problem by applying the unitary theory of energy to the vibrational energy of the atoms of a solid. A more com-

plete and satisfactory theory was put forward in 1912 by Debye, who, instead of assuming a definite frequency characteristic of a particular substance, imagined the solid capable of vibrating so as to yield a whole spectrum of frequencies from zero up to an assigned maximum. Still better agreement with experiment was secured by a modification of Debye's theory proposed by Born and Kármán. Prof. Reiche gives an excellent account of this theory, which regards the solid not as a continuous elastic substance, but as an arrangement of atoms in a space lattice.

Perhaps the most startling application of the quantum theory is found in the remarkable connexion between moving electrons and electromagnetic waves. When light of sufficiently short wave-length is allowed to fall upon a polished metal plate, negative electrons are set free with a velocity v which depends upon the frequency ν of the exciting light. The maximum kinetic energy of an electron ($\frac{1}{2}mv^2$) increases with frequency in agreement with a formula first suggested by Einstein on the basis of the hypothesis of "light quanta." This fundamental law of photo-electric activity may be written

$$\tfrac{1}{2}mv^2 = h(\nu - \nu_0),$$

where ν_0 is a definite frequency characteristic of the metal on which the radiation falls. The equation possesses a very high degree of generality, for it applies not only to ordinary light, but also to X-rays, and appears to be valid not only in the case of emission of electrons under the influence of light, but also when emission of radiation is brought about in consequence of the impact of electrons. The extraordinary problem involved in this reciprocal relation has been well put by Sir William Bragg: "It is as if one dropped a plank into the sea from a height of 100 ft., and found that the spreading ripple was able, after travelling 1000 miles and becoming infinitesimal in comparison with its original amount, to act upon a wooden ship in such a way that a plank of that ship flew out of its place to a height of 100 ft. How does the energy get from one place to another?" "In many ways the transference of energy suggests the return to Newton's corpuscular theory. But the wave theory is too firmly established to be displaced from the ground that it occupies. We are obliged to use each theory as occasion demands, and to wait for further knowledge as to how it may be possible that both should be true at the same time."

The quantum theory of spectral series, with which the name of the Danish physicist Niels Bohr will always be associated, is based on two fundamental ideas. The first is a natural extension of the principle involved in the photo-electric effect. Bohr argued that when an atom emits monochromatic radiation of frequency ν, it must be because the atomic system has lost energy of amount $h\nu$. But a second application of the quantum principle is required in order to fix the "stationary states" of the atomic system, that is, to determine the *permissible* orbits. By the application of these hypotheses Bohr was brilliantly successful in deducing Balmer's and certain similar series emitted by hydrogen, and the series in the enhanced spectrum of helium.

The later and more general formulation of the quantum theory put forward by Wilson, Sommerfeld, Ishiwara, and others, has linked together the various interpretations given for the quantum constant, and has made further progress possible in different directions. Sommerfeld, taking into account the dependence of the mass of the electron upon its velocity, has been able to explain and even to predict the fine structure of the lines in the simpler series, and has obtained results of great interest in connexion with X-ray spectra. Much light has also been thrown by the theory on the resolution of spectral lines under the influence of an electric or a magnetic field.

Attempts have been made with a certain measure of success to apply the quantum theory to explain the facts of magnetism, and the existence of discrete tubes of magnetic induction of strength h/e (where e is the electron charge) has been suggested. To meet the demands of the principle of relativity it may be necessary to postulate discrete electromagnetic tubes, or "calamoids," in four dimensions. Theoretically there is much to be said for the introduction of the "magneton," as one of the ultimate constituents of atomic structure. Here we are brought face to face with one of the outstanding problems of physics. Is the atom a solar system in miniature in which electrons are in rapid orbital motion about a massive nucleus, or is it possible to employ stationary electrons or magnetons to give an approximately statical model? The quantum mechanism imagined by E. T. Whittaker may yield an answer to this question. Then what are we to say as to the bearing of the quantum theory on the still more difficult question of the structure of the nucleus itself!

Prof. Reiche heads his last chapter "The Future," and propounds a series of questions still awaiting solution. "That there are discrete mechanical and electrical systems, characterised by quantum conditions and marked out from the infinite continuity of 'classically' possible states, appears certain. But where does the deeper cause lie which brings about this discontinuity in nature? . . . Is radiation really propagated in the manner claimed by the classical theory, or has it also a quantum character? Over

all these problems there hovers at the present time a mysterious obscurity. In spite of the enormous empirical and theoretical material which lies before us, the flame of thought which shall illumine the obscurity is still wanting. Let us hope that the day is not far distant when the mighty labours of our generation will be brought to a successful conclusion."

H. S. ALLEN.

History of Medicine.

(1) *The School of Salernum: Regimen Sanitatis Salernitanum.* The English Version, by Sir John Harington. History of the School of Salernum, by Dr. Francis R. Packard, and a Note on the Prehistory of the Regimen Sanitatis, by Dr. Fielding H. Garrison. Pp. 216. (London: Oxford University Press, 1922.) 14*s.* net.

(2) *Life and Times of Ambroise Paré* (1510–1590): *With a New Translation of his Apology and an Account of his Journeys in Divers Places.* By Dr. F. R. Packard. Pp. xii+297. (London: Oxford University Press, 1922.) 28*s.* net.

(3) *The Gold-Headed Cane.* By Dr. W. Macmichael. New edition. Pp. xxvii+261. (London: Oxford University Press, n.d.) 16*s.* net.

THE growing interest in the study of the history of medicine to which the recent congress held in London testified (see NATURE, August 26, 1922, p. 296), is further exemplified by the publication of these three fine volumes from the Oxford University Press under the editorship of Dr. Francis S. Packard, editor of "The Annals of Medical History." All the works in question are classics, and perusal of them forms an attractive introduction to the study of medical history, illustrating as they do the development of medicine at different periods.

(1) The "Regimen Sanitatis Salernitanum" is a handbook of domestic medicine written in verse for the benefit of laymen and particularly for Robert, Duke of Normandy, the eldest son of William the Conqueror, who on his way to the Holy Land passed a winter at Salerno in 1096. He visited it again on his return from the Crusades in 1099, to seek relief, it is said, for a poisoned wound of the arm which he had received in the war. As Dr. Garrison points out in an introductory note, in the 14th and 15th centuries there was a veritable flood of hygienic rules addressed to great lords and ladies for their use in travel, campaigns, or pregnancy, all dealing with dietetics, oral hygiene, care of the hair, sleep, etc. The authorship of the "Regimen" is doubtful. Although Daremberg, who published the most complete modern edition in 1830, regarded it as the work of several hands, it is generally attributed to John of Milan, who was head of the School of Salerno at the end of the 11th century. The text of the various copies in existence differs considerably in length. Thus the text annotated by Arnold of Villa Nova (1235–1311), which is used in the present edition, contains 363 lines, whereas some manuscript editions contain less; and others more than a thousand lines. The translation in this edition is that published in 1607 by Sir John Harington, a well-known scholar and courtier of the time of Queen Elizabeth, under the title of "The Englishmans Doctor or The Schoole of Salerne or Physicall Observations for the perfect Preserving of the Body of Man in Continuall Health." The English text is accompanied by notes and embellished by curious illustrations taken from old editions of the "Regimen." A list of the more readily accessible works dealing with the School of Salerno is appended.

(2) The volume dealing with Ambroise Paré will by many readers be found to be the most attractive of the three books under notice. It contains not only a translation in which the spirit of the original is well preserved, of one of Paré's most remarkable writings, but also an admirable sketch of the period in which he lived, including an account of the Faculté de Médecine, the Confrérie de Saint Côme, and the community of barber surgeons, as well as a chronological description of Paré's works. The "Apologie et traite contenant les voyages faits en divers lieux," of which Dr. Packard offers a new and complete translation, was written in answer to a book published in 1580 by Etienne Gourmelen, dean of the Faculté de Médecine, who attacked Paré for his treatment of wounds and his use of the ligature. After showing that he had been preceded in the use of the ligature by a host of great authorities, including Hippocrates, Galen, Avicenna, Guy de Chauliac, Vesalius, Jean de Vigo, and others, Paré relates the histories of cases in which he had applied the method with success. The rest of the work consists of a description of the campaigns in Italy, France, Germany, and Flanders in which Paré took part, and of those whom "he dressed and God cured." The book is copiously illustrated, there being 27 full page plates, 22 text illustrations, and two folded maps of Paris of the 16th and 17th centuries.

(3) A cane in previous centuries was the appanage of every physician, and was usually crowned with a hollow knob of gold, silver, or ivory containing aromatic substances to keep off contagion. The gold-headed cane which has given its name to this volume had a crutch-shaped handle. The book consists of the supposed narration of a gold-headed cane which originally belonged to Radcliffe; and passed successively into the hands of Mead, Askew, Pitcairn, and Baillie, whose

professional careers it describes. On the death of Baillie, whom Sir William Osler regarded as in many ways the most distinguished possessor of the cane, his widow gave it to Sir Henry Halford, who presented it to the Royal College of Physicians, in the library of which it now reposes.

The memoirs of the cane give a vivid account of the social and professional life of the leading London physicians in the seventeenth and eighteenth centuries, including descriptions of the early meetings of the Royal Society. Of special interest is the life of Dr. Mead, of whom it is said that "of all physicians he gained the most, spent the most, and enjoyed the highest fame not only in his own but in foreign countries." Apart from their professional attainments, Mead and Askew were highly accomplished scholars and ardent bibliophiles, the extent of their acquisitions being shown by the fact that the sale of Mead's library took twenty-eight days and that of the *Bibliotheca Askeviana* twenty days. The real author of "The Gold-Headed Cane" was Dr., afterwards Sir William Macmichael, censor to the College of Physicians on two occasions and subsequently physician-in-ordinary to the King. Macmichael also wrote a small and entertaining volume entitled "Lives of British Physicians." The first edition of "The Gold-Headed Cane" was published in 1827, two years after the opening of the present home of the Royal College of Physicians in Pall Mall, and the second edition appeared the following year. A third edition was published in 1884, or forty-five years after Macmichael's death, by Dr. William Munk, registrar of the College, who continued the narrative down to 1871.

Frontier Tribes of Assam.

The Lhota Nagas. By J. P. Mills. With an Introduction and Supplementary Notes by J. H. Hutton. (Published by direction of the Government of Assam.) Pp. xxxix+255. (London: Macmillan and Co., Ltd., 1922.) 25*s.* net.

MR. MILLS'S monograph on the Lhota Nagas is a worthy supplement to the accounts of the Angami and Sema branches of the Naga tribes published by the enterprise and liberality of the Government of Assam, and written by Mr. J. H. Hutton, who has contributed a valuable introduction and notes to the present work. The volume contains a full description, pressed down and running over, of the life of this interesting people, who are now losing their identity by the influence of Christian and Hindu propaganda. A pleasant feature in the writer's work is the sympathy he shows for this childlike people, fully reciprocated by them, who showed their loyalty in the great war and claim to have defeated the Germans under the leadership of their white chief.

The most important part of the book is the introduction, in which Mr. Hutton, with unrivalled knowledge, sums up the latest conclusions on the ethnography of the Nagas. It gives a final blow to the methods pursued by the late Sir H. Risley and his school in dealing with the problems of Indian ethnology. Risley assumed that groups like Brahmans and Rajputs were homogeneous entities, and that it was possible by the measurement of a few skulls, collected haphazard, to

FIG. 1.—A Lhota warrior in full dress. From "The Lhota Nagas."

decide their position in his ethnological scheme. It has now been proved that these groups are in no sense homogeneous, and Mr. Hutton shows that the Naga tribes represent the convergence and assimilation of at least three streams of immigrants. "No Naga tribe is of pure blood, but the area which they inhabit has been the scene of immigrations from north-east, north-west, and south, and the different stocks introduced in this way have entered into their composition. Indeed, in view of the struggles that have taken place for the fertile plains of Burma to the east and India to the west, it is inevitable that some elements worsted in these struggles should have been pushed up into the hills." This is good sense and well expressed, and there is now no justification for accepting a hasty, ill-

considered generalisation, or for assuming the division of the Indian races into a series of water-tight compartments, a view contradicted by the whole course of Indian history.

Among the elements which contribute to the formation of the Naga group of tribes must now be recognised the Negrito, because Mr. Hutton has detected among them examples of a type "with a decidedly dark-brown skin and fuzzy hair." But it is to the Mon-Khmer races, deriving their origin ultimately from China and later from Burma, that we must look for the main constituents of the Naga

FIG. 2.—A medicine man (*Ratsen*) in a fit. From "The Lhota Nagas."

type. Mr. Hutton is possibly pushing the evidence a little too far when he suggests a comparison between a form of spear with ornamental barbs curving outwards from the shaft, a peculiar dao knife, and a shouldered hoe, with similar weapons and implements used by the Igorots of the Philippine Islands, as proving the common origin of these races. The general conclusion is quite acceptable, but it will need much further exploration to bring to light that amount of material by which so wide a generalisation can be established. But Mr. Hutton, who writes in a scholarly way and without any trace of dogmatism, is clearly working on scientific lines, and his admirable introduction throws much-needed light on the connexion of the races of eastern India with those of the Malay Peninsula and the islands farther east. It thus marks a decided advance towards the settlement of some of the most urgent problems of Indian ethnology.

Mr. Mills's work is an excellent example of field-work in ethnology, and it only remains to say that his monograph is furnished with a fine series of photographs, maps, and an admirable index compiled by Lieut.-Col. J. Shakespear.

Our Bookshelf.

An Introduction to the Chemistry of Plant Products. By Dr. Paul Haas and T. G. Hill. Vol. 2: Metabolic Processes. Pp. viii+140. (London: Longmans, Green and Co., 1922.) 7*s.* 6*d.* net.

THE first volume of this work is already well known to students of plant physiology; first issued in 1912, it is already in its third edition. In this third edition the more physiological problems were left for treatment in this second volume, which is in effect a completely new book. In the brief preface the authors describe their choice between the alternative methods of treatment, and every student will be grateful for their courageous decision to attempt a connected account of the present state of our knowledge rather than an encyclopædic digest of the literature. The result is a book much more open to criticism but infinitely more valuable.

After a brief introductory section, devoted mainly to modern methods of measuring and expressing hydrion concentration, the synthetic metabolism of fats, carbohydrates and proteins is briefly considered, and two long chapters dealing respectively with respiration and growth conclude a short but exceedingly suggestive volume.

In the reviewer's opinion, the authors have done a great service to botany by their clear, concise and eminently readable treatment of their subject. The brevity of the section devoted to fats probably adequately reflects our ignorance of their metabolism in the plant, though one would have liked to see reference to the recent investigations of Neuberg and his collaborators. The section on photosynthesis forms an admirable complement to the monograph upon carbon assimilation by Jorgensen and Stiles, which considers the same problems from a more physical point of view.

The treatment of protein metabolism is somewhat scanty, again a correct reflection of our ignorance, but an introduction to the recent work upon the relation of hydrion concentration to the chemical and physical behaviour of the amphoteric protein would have been very valuable for the English reader. The emphasis given to the dehydrase mechanism in the treatment of respiration seems to the reviewer entirely sound; until oxidase mechanisms can be proved more effective upon sugars, their significance as a general respiratory mechanism must remain under suspicion. The chapter

on growth is very clear and well balanced; it is probably too early to hope for a critical treatment of the metabolic machinery of growth—at present there is very little metabolism in this chapter.

Among the Head-hunters of Formosa. By Janet B. Montgomery McGovern. Pp. 220+plates. (London: T. Fisher Unwin, 1922.) 15*s.* net.

ALTHOUGH Mrs. McGovern's interesting account of the aborigines of Formosa is written for the general public rather than the scientific reader, it is welcome as a first instalment of the information she acquired during her two years' stay on the island. Our knowledge of these peoples is very defective, and the more detailed study which she promises will be awaited eagerly. In this book the author draws an attractive picture of a people of many virtues, notwithstanding their head-hunting proclivities. Their culture and social organisation are of considerable interest, not the least noteworthy feature being the existence of a matriarchate vested in priestesses. Their religion consists mainly in reverence for their ancestors, but among the Taiyals, whose mountainous country is subject to violent rain-storms, the rain-devil is naturally of much importance. They do not, however, propitiate him, but avert his unwelcome attentions by a ceremony in which the priestesses, armed with knives, engage in what is clearly a combat with the spirit.

The aboriginal tribes show no traces of totemism or exogamy, although the marriage of first cousins is strictly prohibited. Their language belongs to the Malayan family, and the author considers that the affinity to the Indonesian peoples, which has been suggested by other writers, is supported by the occurrence of the nose-flute and pile-dwellings among them. In this connexion it may be noted that the prominence of priestesses in religious ceremonies, the sacred character of certain jars, and the significance of birds as omens, find a close parallel in the customs of certain tribes of Borneo.

Bureau of Education, India. Occasional Report No. 9. The Planning and Fitting up of School Laboratories. By M. C. S. Anantapadmanabha Rau. Pp. vii+40+8+18 plates. (Calcutta: Government Printing Office, 1921.) 1.4 rupees.

WORKS upon the material requirements of laboratories are very few, and as this subject is growing in importance published information is always to be welcomed. The first sixteen pages of the report deal with the general planning and relation of rooms and the arrangement and characters of the fittings they contain. In the remarks on construction it is surprising to see "brick nogged" partitions recommended as light suspended walls; in this country it has become rare even to find such construction in re-modelling buildings. The author proceeds to describe the fittings in detail, and while he gives a valuable summary every one will not agree with all his recommendations; thus he suggests lead for the bottoms of fume cupboards, and that the gas jet operating the draught should be placed at the top of the ventilating shaft near the exit, which would usually be a very inconvenient location. The plates which occupy the greater part of the volume give a series of good diagrammatic figures of fitting and plans of rooms, showing how these are laid out. These drawings are fully dimensioned and should prove of service in designing, though here again some difference of opinion may arise on the use of details; for example, metal handles, indicated for bench drawers, seem open to question. These are small criticisms and the volume will undoubtedly prove of considerable service.

A Summer in Greenland. By Prof. A. C. Seward. Pp. xii+100+29 plates. (Cambridge: At the University Press, 1922.) 7*s.* net.

Two months in west Greenland, where he went to collect fossil and recent plants in the summer of 1921, taught Prof. Seward the fascination of polar regions. Every chapter of this charming little book shows that the country has cast its spell over him. He does not attempt to justify his publication, but no justification is necessary. The book is a welcome addition to the literature of polar regions, for very little on Greenland has appeared in English in recent years. The author deals mainly with the botany and geology of the country, but there are some notes on its people and history, and a number of excellent illustrations and two maps. In the comparison of Arctic and Antarctic floras a correction may be made. Prof. Seward is mistaken in saying that not a single flowering plant has been discovered within the Antarctic Circle. The grass *Deschampsia antarctica*, which he cites from lat. 62° S., where, by the way, a true Antarctic climate occurs, was found, along with *Colobanthus crassifolius*, in lat. 68° S. in the west coast of Graham Land by the French Antarctic expedition in 1909. Another small point may be noted. Thule, in lat. 76° 35′ N., on the west coast of Greenland, is not the most northerly settlement in existence. Even if the Eskimo camp of Etah in lat. 78° 20′ N. be passed over, there is the large Norwegian coal-mining settlement of Nyaalesund in King Bay, Spitsbergen, in lat. 78° 55′ N.

Stories from the Early World. By R. M. Fleming. Pp. 156+12 plates. (London: Benn Bros. Ltd., 1922.) 15*s.* net.

THE success which has attended Miss Fleming's book, "Ancient Tales from Many Lands," has encouraged her to publish a second collection of tales dealing with the early world. In an interesting summary of the conclusion Prof. H. J. Fleure tells us that folk tales "have as their basis the interest of men in one another's ways when even neighbour people had very distinct civilisations." These tales cover a wide area and represent various phases of ancient life. One from America illustrates life before the domestication of animals, but recent investigation shows that cultivation is in many regions as old as herding. Many stories indicate the beginnings of trade and the social value of craftsmanship in the earlier development of settled life. That of Crœsus suggests the conflict between farmer-fishery in the Ægean and the warrior tribes of Media. That of Bilkis, Queen of Sheba, shows the Hebrews from the point of view of Islam, but Miss Fleming might have given the incident when Solomon hears that the Queen's legs were hairy, and forces her to raise her skirts in passing over the glass floor of his palace, believed to be a river, one incident which has parallels from India, strangely omitted in this world-wide survey. But folk

tales must not be pressed too far as evidence of prehistoric or ancient life. They have wandered too much to be distinctive of special types of culture—what is permanent is the incident, which is combined in many ways according to the fancy of the story-teller. The book, as a whole, is interesting and suggestive, and supplies excellent reading for children.

Marine Works: a Practical Treatise for Maritime Engineers, Landowners, and Public Authorities. By E. Latham. Pp. xii+174. (London: Crosby Lockwood and Son, 1922.) 16*s.* net.

THE scope of Mr. Latham's book is fairly wide, as may be seen from the following brief list of subjects treated: waves, maritime structures, tidal berths, pile-driving, marsh lands, coast defence, navigable rivers, scour and deep-water quays. There is also an appendix on legal aspects of maritime engineering. The treatment of these subjects is a little uneven. Some parts of the volume are detailed and contain much useful information, particularly in regard to unit cost prices of work actually carried out. Elsewhere, there is a superficiality a little out of keeping with the title of "Treatise." For example, in the first chapter the author states that "the theory of wave action is of little practical value," and dismisses the matter with some scanty reference to certain writers who would scarcely claim that their contributions to the literature of the subject are as weighty and authoritative as those by others whose names are ignored. This rather slighting allusion to theory is scarcely justified by the facts. There are other opinions and views expressed, to which exception might be taken, but apart therefrom, there is much that is useful as an addition to technical knowledge. The book is stated to be the outcome of sixteen years' professional practice, and as such should be of value to practical engineers.

(1) *Second Year College Chemistry.* Pp. xi+311. 15*s.* net. (2) *Second Year College Chemistry: a Manual of Laboratory Exercises.* Pp. vii+115. 7*s.* 6*d.* net. By Prof. W. H. Chapin. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.)

(1) PROF. CHAPIN'S book has, for English readers, a somewhat misleading title. It is not an elementary treatise on inorganic chemistry, but a clear and very interesting introduction to general and physical chemistry—"the general principles which are the framework of our science." The gas laws, atomic and molecular theories (including the periodic system, radioactivity and the structure of the atom), solutions, equilibrium, and electro-chemistry, are all reviewed from the modern point of view, and the result is a readable, accurate, and stimulating book for junior students in universities.

(2) This is a companion volume to the "Second Year College Chemistry." The experiments include an elementary course in practical physical chemistry, and some of them are new. Although the practical courses in English institutions are differently arranged, Prof. Chapin's book will be found useful by teachers in the physical chemistry laboratory, as well as by lecturers on this subject.

Secret Sects of Syria and the Lebanon: a Consideration of their Origin, Creeds, and Religious Ceremonies, and their Connection with and Influence upon Modern Freemasonry. By B. H. Springett. Pp. 351. (London: G. Allen and Unwin, Ltd., 1922.) 12*s.* 6*d.* net.

MR. SPRINGETT'S aim is to show that the rites of Freemasonry are derived from the mystic religions of the East. These, in turn, he holds, can be traced through the ancient religions of Egypt and Mesopotamia to the stellar and solar cults of prehistoric times. He attempts to prove his case by a statement of the esoteric beliefs to which initiates were introduced by a regular gradation in such early cults as the Eleusinian mysteries, Mithraism, Zoroastrianism, the doctrines of Pythagoras, the Gnostics, and the Manicheans, as well as in Mohammedanism and its various sects. He suggests that Freemasonry can be connected with these beliefs through the Knights Templar who, he holds, had probably adopted the tenets of the Manicheans and had been influenced to a considerable degree by the Ismæli, the followers of the Old Man of the Mountains, known to the medieval world as Assassins. It may be pointed out that in many cases our knowledge of these secret tenets is of doubtful accuracy, while the evidence against the Templars is of little value. Owing to the author's lack of archæological knowledge, many of his arguments will not bear critical examination, while they embody a number of errors in matter of detail.

Química Experimental. By Prof. Roman Galarza. I: Mineral. Curso de Química Científica, con los Principios Recientes de la Físico-Química, para Uso de las Escuelas Normales y Colegios Nacionales. Pp. 128. (Córdoba: Angel Alvarez, 1922.)

THE volume before us is an introductory treatise on a very original plan. There is a full account of laboratory arts, with many useful recipes and practical hints; a very interesting historical narrative, which embodies a good deal of material not usually met with; and a description of some of the common elements, including physical chemistry. The book would be found very interesting and useful by chemical students learning Spanish. There are some trifling errors: Newton "nacido en Voolsthospe," which reminds one of the English Alchemist "Germspreiser" [James Price] of Figuier.

More Beetles. By J. Henri Fabre. Translated by A. Teixeira de Mattos. Pp. viii+322. (London: Hodder and Stoughton, Ltd., 1922.) 8*s.* 6*d.* net.

THIS is the fourth and last volume on beetles in the collected English edition of Fabre's entomological works. It is of special interest in containing the complete account of the habits of the dung-beetle *Minotaurus typhæus*, which, almost alone among insects, presents the phenomenon of the male collaborating for many weeks with the female in providing accommodation and provisioning the larder for the offspring. In several chapters Fabre's scorn of the theory of evolution is strongly in evidence, notwithstanding that he adduces numerous instances of exquisite adaptations of structures to the habits of individual species, and at least one of sexual selection.

Letters to the Editor.

The Function of Mendelian Genes.

IN NATURE for January 20, p. 74, Prof. MacBride makes a statement which appears to me to rest upon a fallacy. Since this fallacy is not uncommon, and since it concerns a very fundamental problem, I feel that perhaps a discussion of it in these columns may serve a useful purpose.

Prof. MacBride, in the review referred to, writes as follows: "Prof. Reinke encounters the Mendelian 'gene' and in our opinion takes it far too seriously. . . . It is becoming every day clearer *that a 'gene' is not a definite unit of structure at all, but simply the measure of the amount of pathological damage which the hereditary substance has undergone.* [Italics in the original.] It is a measure, in a word, of the 'imperfection of regulation.'"

The fallacy involved is simply this—that Prof. MacBride is using the word "gene" as if it meant "mutant gene." A mutant gene is, strictly speaking, that portion of the hereditary constitution which is responsible for the characters of a mutation observed to arise in Nature or in the course of experiment. I take it, however, that Prof. MacBride is considering all definite variations which are inherited according to Mendel's laws, whether their origin was observed or no; this at any rate is now a legitimate extension, and I shall employ "mutant gene" to denote the altered portion of the hereditary constitution responsible for variations inherited in a Mendelian way.

Now in point of fact, as Morgan himself and other writers have taken great pains to point out, the discovery of each new Mendelising variation, of each new mutant gene, implies also the discovery of an allelomorphic "normal gene" responsible for the production of the "normal" structure and function of the part or parts affected by the mutation.

The work on Drosophila has completely proved that Mendelian genes are carried in the chromosomes. Prof. Bateson, for long sceptical on this point, finally conceded it last year after seeing the work of Morgan and his pupils at Columbia University, New York. Further, it has proved that within each chromosome the genes are arranged in a definite way; the observed facts are intelligible if we assume that the genes are arranged in a constant and linear order, while no satisfactory alternative hypothesis has been put forward.

In any case, the order is identical for all the homologous chromosomes of the species which are tested. A mutant gene, therefore, occupies a similar position in one particular chromosome to that which is occupied in the corresponding chromosome of the normal wild strain by an allelomorphic gene which has not mutated. The mutant differs from the non-mutant gene by some definite alteration, presumably of a chemical nature: the existence of series of multiple allelomorphs, together with other evidence, proves that a recessive gene is not a mere total absence of the something we call the dominant gene. That is to say, in the chromosomes of the normal wild-type animal or plant there exist a large number of genes or factors the chemical constitution of which cannot be altered without giving rise to "mutations." Some of these mutations are pathological; others (*pace* Prof. MacBride!) are not.[1]

[1] See *Science Progress* for 1921, where Prof. MacBride, in answer to two letters of mine, eventually admitted that not all were pathological. This question, however, does not concern the present argument at all.

But even if they were *all* pathological, this would not alter in the very slightest the fact that their non-mutant allelomorphs constitute an orderly series of discrete units distributed in heredity by the chromosome mechanism (*i.e.* according to the laws of Mendel as extended by later research), and *all* necessary for the *normal* development of the individuals of the species. Of course, if all mutations were pathological, Mendelian genes would have no significance for evolution. However, they would even so continue to have the most fundamental significance for normal heredity.

Perhaps my meaning may be made clearer by a brief example. In the wild house-mouse, each hair is black with a yellow band across it, the yellow and black blending to give an appearance of grey; grey of this type is technically called "agouti." Black mice are mutants in which the yellow band is absent; this condition is recessive to normal. Yellow mice, on the other hand, have the yellow pigment extending the whole length of the hair; and yellow is dominant to grey (agouti). It is also dominant to black. The three types of colour and their behaviour in crosses can only be explained if we suppose that there is a definite gene responsible for the production of yellow pigment, and that this exists in three separate states—a "strong" state when a great deal of the pigment is produced, a "medium" state in which a moderate amount is produced, and a "weak" or non-effective state in which no yellow pigment is formed at all. The gene in its medium state is responsible for the particular proportion of yellow which we see in the hair of wild house-mice. The three states are all allelomorphic to each other, the "normal" being a Mendelian recessive as against yellow, a Mendelian dominant as against black. It is impossible to escape from the idea of a discrete unit of definite composition helping to determine coat-colour in the normal animal, strictly comparable to the homologous units responsible for the two "mutations."

This example is also of service as regards the abnormality or otherwise of mutations and mutant genes. The alteration productive of all-yellow is decidedly pathological. Even a single dose of this gene leads to excessive fatness, and two doses cause death of the fœtus *in utero*. The recessive "black" gene, on the other hand, does not appear to be responsible for any pathological effects. What is more, there is no evidence against the view that this mutant black is strictly comparable to the black of melanistic mammals in Nature, and the similarity is so great that the onus of proof lies on those who would dispute this homology.

In any event, there are two quite distinct aspects of the gene question—the genetic or hereditary, and the evolutionary. Mutations in Mendelian genes may or may not have been responsible for variation which has played a part in evolution. This I do not propose to discuss here, except to say that I know from many conversations that Prof. MacBride's views are too sweeping for a number of zoologists. But as regards inheritance within the species, the Mendelian gene—once the fallacy of confusing "mutant gene" with "gene" is seen and avoided—is clearly and obviously of importance.

We are to-day in a position to make a calculation of the order of magnitude of the number of genes in the chromosomes of Drosophila. It is certainly more than 1000; probably more than 2000; certainly less than 20,000. The effects of alterations in more than 200 of these genes (*i.e.* mutations) have been observed and studied; there is no sign that the rapid stream of new-discovered genes is slackening. With such a number of genes responsible for keeping the development of a little fly in the straight and narrow path of normality,

there seems very little room or need for subsidiary mechanisms of heredity. The cytoplasm presumably has its functions in this regard; but the absence of accuracy in cytoplasmic division, together with the presence of this large battery of genes in the accurately divided chromosomes, make us sceptical as to its possessing many "heredity-determining" substances. Finally, there is no reason to doubt and a good deal of reason to believe that all higher animals and plants possess chromosomal gene-complexes similar in essentials of structure and working to that so thoroughly analysed in Drosophila.

Age and Area and Natural Selection.

I AM not especially eager to defend Dr. Willis's theory of "Age and Area." My chief interest in Dr. Willis's views is that they agree with those of Dr. W. Bateson and myself in accepting and confirming the conclusion that the distinctions of species have as a rule nothing to do with adaptation, and therefore nothing to do with Natural Selection.

Dr. Clark states (NATURE, February 3, p. 150) that every systematic zoologist whom he knows believes in Darwin's theory. But I long ago became convinced that the knowledge of systematic zoology, however profound and however accurate, confers no right to, and affords no justification for, the expression of opinions on questions of evolution, or at least on the causes and processes of evolution. To form a judgment on such questions requires certainly knowledge and experience of systematic zoology, especially of its principles and of the species in some particular group or groups of animals, but it also requires a practical knowledge of modern researches in genetics, of cytology, of certain branches of physiology, and of the life and habits of some group or groups of animals.

At the present time zoologists are usually specialists, and each specialist gives forth conclusions about problems of evolution based almost exclusively on the phenomena of his own special study. Dr. Bateson believes that no facts are of any great importance except those of genetics, that is to say, of the behaviour of characters in experimental breeding, and pays little or no attention to the question of adaptation. Prof. MacBride, on the other hand, a specialist in embryology, asserts that the characters and mutations studied by geneticists are merely pathological, and that all natural varieties are distinguished by differences of adaptation, due presumably to the action of external conditions. Dr. Clark apparently believes that diagnostic characters are all adaptive and to be explained by Natural Selection.

Dr. Clark states that his own special group is that of echinoderms. I wonder whether he has studied the mode of life of the species and varieties of echinoderms in Nature, and if he could bring forward any evidence to show a correlation between specific differences and differences of habit and mode of life. Many of the older systematists, holding no brief for any theory, recognised (and I think correctly) that there is a general distinction between characters which show natural affinities and are therefore most important in classification, and adaptive characters which are related to habits and conditions. Natural Selection is a theory of the origin of adaptations, and in my judgment there is ample evidence that specific differences are not as a rule differences of adaptation. Therefore Natural Selection does not explain specific differences. It is recognised now that in the cultivation of animals and plants the marked and constant characters which distinguish races are not, as Darwin believed, the gradual result of continued selection, but are mutations which have arisen spontaneously in definite form, not by successive stages. Does any one believe now that the rose comb in fowls is the result of a series of stages due to artificial selection?

If Dr. Clark would do me the honour of reading my book "Hormones and Heredity," he would find these matters more fully discussed, and would perhaps understand better why I consider the theory of Natural Selection to be obsolete. That conclusion, of course, is not disproved by the fact that many naturalists still believe in the theory, in America and elsewhere. But there are specialists in evolution as well as in systematic zoology and in other branches, and I venture to say that few who have made a special and practical study of evolution and are well acquainted with recent progress in that study, have much faith in Natural Selection.

It is evidence which is important rather than opinions, and I would ask what evidence Dr. Clark can bring forward to prove the adaptive value of specific and other diagnostic characters in echinoderms. Personally I am not interested in the explanation of the origin of species, but in the origin of the particular characters which distinguish one species from another.

The Value of e/m.

IT is quite customary, at the present time, to use as the most probable value of e/m that derived by Paschen from spectroscopic data, as given by equations (12) and (13), page 272, and (15) and (16), page 275, of Sommerfeld's "Atombau," third edition. Taking Paschen's own estimate of the error in R_{He} and R_H, we have a probable error in e/m of about 0·2 per cent. But I have shown by a more detailed consideration of all available data (*Physical Review*, 17, 589, 1921) that Paschen's estimate of error for R_H ($\pm 0{\cdot}06$) is certainly too small, and that the true probable error is nearer $\pm 0{\cdot}2$. The latter figure leads to an error of 0·5 per cent in e/m, and the Paschen data, combined with the best data on atomic weights (4·002 and 1·0077 for He and H) result in $e/m = 1{\cdot}768 \pm 0{\cdot}009$, where the error in R_H has alone been considered.

Paschen used older and less accurate values for the index of refraction of air, in his reduction to vacuum. With the new values Bell (*Philosophical Magazine*, 40, 489, 1920) has shown that the value of R_{He} is raised 0·17 to 109,722·31. Since the calculation of this constant is independent of any particular assumptions as to the relative intensity of fine structure components, it is probable that this revised value is quite trustworthy, and I shall assume Paschen's own estimate of error, $\pm 0{\cdot}04$. The calculation of R_H is much more uncertain. Using the original Sommerfeld theory, as Paschen did, but all available data and the newer values for the reduction to vacuum, I have shown (*loc. cit.*) that Paschen's value of R_H is raised 0·14, to 109,677·826. But experimental results agree more closely with the more rational Bohr theory as to the intensity relations, and this theory yields a value of R_H lower by 0·21. Any lowering of the 2 to 1 intensity ratio of the Balmer series components leads to a lower value of R_H. I have suggested 109,677·7 as the most probable value of R_H, this being the mean value yielded by various theories. This value, combined with Bell's revised value of R_{He} gives 1·762 for e/m.

Finally, the new data by Wood (*Philosophical Magazine*, 44, 538, 1922) on the extended Balmer series makes possible a new computation of R_H. I find that these new measurements are entirely consistent with the previous data, and yield 109,677·6, with an assumed intensity ratio of 5 to 4. (A 1 to 1 ratio lowers this result 0·08.) There seems to be no question that the two fine structure components, with the exception of H_α and H_β, are of nearly equal intensity. I am therefore inclined to consider 109,677·6 as a preferable value for R_H, and this yields 1·758 for e/m, a value for which the probable error is fully 0·5 per cent. The point I should like to emphasise is that the newer experimental results for hydrogen indicate that $R_{He} - R_H$ must have a larger value than that computed by Paschen, and hence e/m must be smaller, but that the probable error is much greater than that assumed by Paschen. I have previously (*Physical Review*, 14, 363, 1919) used 1·773 as the most probable value of e/m, and while this value may be slightly too large, I still feel that it is more trustworthy than the spectroscopic value of 1·758. Without a considerable advance in our experimental knowledge of the fine structure of the hydrogen lines, it is scarcely possible to diminish appreciably the uncertainty in this latter value. New experimental data on the value of e/m, derived from deflection experiments or from the Zeeman effect, are greatly to be desired.

Sir Christopher Wren's Science Museum.

At the present time, when the thoughts of all are being directed to the fifty churches and innumerable other buildings that are associated with the name of Wren, reference may appropriately be made in NATURE to his epoch-making work for science during the best twenty years of his life, to his scientific instruments, and to his Science Museum (Fig. 1). His instruments, after having been piously preserved for many years in the repository of the Royal Society at Gresham College, have now vanished, but his building, the Old Ashmolean Museum, is still standing, though no longer used for the purpose for which it was intended.

FIG. 1.—Wren's Science Museum at Oxford. (After Mackenzie and Le Keux, Memorials, 1834.)

Since the destruction in 1767 of Gresham College, the venerable seat of learning and science, where the original members of the Royal Society used to hold their meetings, no existing building is more closely associated with the spirit of the time of the foundation of that society than is the Old Ashmolean Museum.

On the occasion of the 300th anniversary of the birth of Ashmole, this building was described in NATURE of May 17, 1917, as our first public Museum of Natural History, and now, on the occasion of the bicentenary celebrations in honour of Sir Christopher Wren, we would emphasise the intimate connexion it has with the great architect, who owed much of his surpassing merit in the arts to the preliminary training that he had in Oxford as a man of science.

Elmes, in his "Life of Wren" (1823), attributes the Ashmolean Museum to him, but as some recent writers have cast a doubt upon the matter, I have examined all available materials, and have come to the conclusion that there is every reason for upholding the correctness of Elmes' attribution. According to the Vice-Chancellor's Accounts, the building of Dr. Ashmole's Repository took about four years (1679–83), during part of which time Wren was engaged on other important works in Oxford. It was erected only a few yards from the Sheldonian Theatre, his earlier work: a science museum would scarcely have been placed so near without having consulted Wren. There is no record of any fee having been paid to him, but he would have known that the University was barely able to meet the building expenses of the new Museum, and it is known that on occasions he gave his services free. As president of the Royal Society, and as builder of some half-dozen churches in London, he was fully occupied elsewhere during the construction; and the work of supervision was entrusted to Mr. Davis, the University Bailiff, who received 80*l.* for this service. Wood, the stone-cutter, received 1912*l.* 5*s.* 5*d.* for the masonry work, and the accounts of the carpenters, plaisterer, plumber, painter, and glazier were settled separately.

A finely designed portal, flanked by columns and opening under a richly ornamented canopy, leads into a large room running the whole length of the building, about 58 ft. 6 in. long by 24 ft. 10 in. wide. It is lit by five high windows on the north side. On the upper floor a similar room has been divided into two, which are perhaps the best lit rooms in Oxford, having large windows on three sides, N., S., and E. or W. It is necessary to emphasise this point, because a contrary statement, disparaging Wren's building, appeared in the *Times* for December 2, 1922. The windows are about 10 ft. high by 4 ft. 6 in. wide, and there are no dark corners anywhere.

The illustration printed with this letter shows the balustrade round the roof of the building. It is the counterpart of the contemporaneous work at Christ Church, and of the earlier work on the Sheldonian Theatre. Wren was very partial to balustrades. Moreover, it stands within the railing that was undoubtedly designed by him.

When recalling the connexion of the Museum with two of the first fellows of the Royal Society—Wren

and Ashmole—the link with the founder of the Society should not be forgotten; the monogram of Charles II.—"C. II."—is carved over the fine balcony window in the middle of the front of the building.

It is on account of these various associations with British science and the early days of the Royal Society that a petition has been laid before the Hebdomadal Council of Oxford, requesting that the vacant rooms in the old Museum may be once more used for the purposes of natural science for which they were built.

Magdalen College, Oxford.

Tesla Spectra of Complex Compounds.

IN NATURE of January 27, p. 115, a very interesting letter appeared by J. K. Marsh and A. W. Stewart on "Tesla Spectra and the Fraunhofer Effect in Complex Compounds."

More than a year ago I began an investigation of the band spectra of benzene vapour under the action of high-frequency discharges. Both the absorption and emission spectra were examined. Other more complicated substances were also tried in a state of vapour.

Upon varying the capacity, and more especially the self-induction, as well as altering the vapour pressure between wide limits, *emission* bands can very clearly be seen. Each substance has a characteristic spacing of the emission bands; they appear in a perfectly definite order. Nitrogen is a very good example of this.

In the case of benzene, I photographed a whole series of emission bands which lie very close to its absorption and fluorescence bands. I referred briefly to this in my article on "Spectres d'absorption et de fluorescence du benzene" (*Journal de Physique et le Radium*, Juin, 1922, p. 210).

J. K. Marsh and A. W. Stewart express the wish to reserve for themselves the further examination of Tesla spectra. I should only like to say here that we have been working for a long time on similar ground, but one thing is certain, that we have been working from entirely different points of view. Our principal object is to work out the structure, size and shape of the molecules from their band spectra.

Our investigations, and those of Messrs. Marsh and Stewart, should therefore be of mutual advantage one to the other.

The subject is so vast that the more it is investigated, the sooner will the question of the band spectra be solved.

VICTOR HENRI.

Institute of Physical Chemistry,
University of Zürich,
February 2.

WHEN our letter to NATURE of January 27 was written, we were under the impression that we were the only workers in this field, as the researches of Wiedemann, Eberts, and de Hemptinne in 1897 and earlier years had led to no results in the particular region which we were investigating. Prof. Henri has courteously sent us a private communication as well as the above letter, and has forwarded also a copy of the paper which he mentions. In this paper occurs the following sentence: "Nous avons entrepris une série de recherches pour étudier la fluorescence et la luminescence de la vapeur de benzène sous différentes conditions, en particulier sous l'influence de décharges électriques diverses." As was natural in the case of a long paper, this sentence was not reproduced in the abstract which appeared in the Chemical Society's Journal; and as we had no access to the *Journal de Physique et le Radium* itself, we were quite unaware that any one was working in the field. Thus our work and the unpublished results of Prof. Henri are entirely independent of each other; and we are anxious that the mere accident of our having been first in actual publication of detailed results should not in any way deprive Prof. Henri of his full share in the credit of the discovery and investigation of these new spectra.

As Prof. Henri says in his letter, the subject is being approached along two separate lines, as we are mainly interested in the relation between the chemical constitution of substances and the spectra produced by them, whereas he is working back from the spectra as a basis to the machinery which produces the spectra within the molecules and is investigating also the variations produced by different electric wave-lengths—a subject which we have no intention of entering upon now, since it is in his hands. Our lines of research therefore supplement each other; and we cordially agree with Prof. Henri that there is more than enough room for both our laboratories to work in this interesting new field. We should like to express our appreciation of the courtesy which Prof. Henri has shown in this matter.

Calendar Reform.

DURING the 16th century Pope Gregory XIII. effected a very necessary rectification of the Julian Calendar, which was not, however, legally adopted in England till 1752. The effect of the correction was to bring forward the dates of the solstices from about the tenth to the twenty-first of June and December; but the climatic significance of this astronomical dislocation in the calendar was not serious, and the calendar months retained the same distinctive seasonal characters as heretofore. As, therefore, the present calendar is the same in essentials as that instituted by Julius and Augustus Cæsar some 2000 years ago, it must have come as a surprise, possibly a shock, to many readers of NATURE (December 2, p. 747) to learn that we may shortly be asked to suffer all the inconvenience and confusion of a catastrophic alteration in the calendar on grounds which seem altogether trivial. In the first place, the calendar months now in use have by long association become enshrined in literature as the very impersonation of definite stages in the seasonal progression and retrogression of natural phenomena, and it would be sheer vandalism to break this association, and renounce our literary heritage, without far graver practical cause than can possibly be shown.

In the second place, every calendar system must be framed with reference to the four natural landmarks of the year, namely, the solstices and equinoxes, and it is eminently desirable that the two solstices, and the two equinoxes, which stand opposite one another in the natural year, should not be assigned dates which are unsymmetrically disposed to one another. In the proposed system of 13 months, the solstices would stand 6½ months or time-units apart, instead of a whole number as in the present system, and no month would be located diametrically opposite another as at present, viz. December to June, March to September, and so on, along the earth's orbit round the sun. This arrangement would offend the artistic sense of any one with a vivid appreciation of the fact that our fundamental division of time, the year, is not an arbitrary unit but one based on a grand cycle of Nature.

Thirdly, it is said that meteorologists and astronomers would welcome months with equal numbers of days, and no doubt they would, one and all, if they could order everything to perfection. But apart from the labour that would be involved in preserving the continuity of the climatological record, involving the translation of one calendar into the other, think of the confusion that would arise in making comparisons between two systems which both have the same names of months! We should be perpetually having to think and specify whether it is the old *January* or the new *January* we are considering, and so forth. It would be just as though, when the new barometer unit the *millibar* was instituted to replace the *inch*, the name "inch" had been retained for the new division. Far better would it be to have an entirely new set of calendar names so that the old names would retain their habitual meanings. It is always open to astronomers and meteorologists to invent a system for any special technical purpose for which it may be required; but probably not many of them would take the narrow view and wish to disorganise the world on that account.

This country can, when it likes, be very much to the fore when issues of real importance are involved: but with a sane respect for tradition it is scarcely likely to countenance interference with a system of time-measurement the correction of which by Pope Gregory XIII. was designed to hold good for a very long period ahead. L. C. W. BONACINA.

January 27.

Time Relations in a Dream.

I WAS much interested by Dr. Atkins's letter in NATURE of January 27, p. 117, about time-rate in dreams, and more especially by what he says of the metallic nature of the sound as heard in the dream. This fits in with an observation I made a couple of years ago when I was in lodgings close to a bell-tower. It happened that for other reasons I was not sleeping well at the time, and was frequently waked by the bell ringing hours and quarters. It always seemed then of much higher pitch when I heard it in a dream, or even when I was just awake enough to recognise the source of sound, than when I was fully awake. Several times I could follow the same sound repeated during my transition from sleep to waking, and then found that I really heard the upper notes of the bell in their true pitch, the lower notes being completely blocked out.

Though I have since been able to verify this interpretation nearly to my own satisfaction, I should be glad if any one else could confirm it in any way, as, in the nature of the case, it is difficult to be certain of one's judgment. Can the physiopsychologists help towards an explanation, assuming I am right?

H. F. BIGGS.

The Electrical Laboratory,
Oxford, January 29.

The Ascent of Elvers in Egyptian Waters.

IN connexion with Dr. Schmidt's article on the "Breeding Places and Migrations of the Eel" (NATURE, January 13, p. 51), it may be of interest to give the results of further observations upon the arrival and ascent of elvers in Egyptian waters. The records were made at the pumping-station mentioned in Dr. Schmidt's article. The station is exceptionally favourable for such observation, since skilled observers were (and are) present day and night (in connexion with other fishery work) throughout the year. There can be no doubt, therefore, that when elvers were reported absent there were in fact none to be seen. Since the pumping-station ceases to work early in the summer, this fact may bring the ascent artificially to an end; but, as a rule, there are signs that the main run is over before the pumps stop. The numbers transported are given as an indication of the extent of the "runs."

All the early "runs" consist of transparent elvers; from the middle of April onwards about 50 per cent. are pigmented.

The observations are as follows:

1919–1920 Season: No observations prior to January 20, 1920, on which date transparent elvers were abundant and remained so until April 15, when the pumps stopped working. Reappeared in large numbers on the nights of July 2, 3, and 4. Total transported, 6,260,000.

1920–1921 Season: First observed December 15, 1920 (also on some date in Lake Menzaleh, near Port Said); remained few till January 30, when they appeared in large numbers for two nights only; then disappeared completely until April 7, when they were present for three successive nights. Appeared again April 19–May 24, when pumps ceased working. Total transported, 1,797,000.

1921–1922 Season: First observed on November 11, 1921, in small quantity till January 20, 1922; remained abundant till February 20, 1922; disappeared till March 23, continuing in decreasing numbers until April 10, when pumps stopped. Total transported, 2,484,000.

1922–1923 Season: First observed October 25; remained in small numbers until December 4, when they were abundant for two nights; remained few in number to date, January 24, 1923.

From the above, it may be observed:

(1) That elvers may make their first appearance at a given place nearly two months later in one year than another.

(2) That the dates of first appearance in Egypt are the same as those recorded for the West of Ireland, France, and Spain—say, 1500 miles nearer the suggested centre of dispersal in the Western Atlantic.

(3) That the main "runs" occur in the same months (February–April) in rivers as widely separated geographically as the Severn, the Po, and the Nile, notwithstanding the very different climatic conditions obtaining in these months in the last-named region.

G. W. PAGET.

Coastguards and Fisheries Service, Cairo.

Transcription of Russian Proper Names.

IN order to conclude the discussion which followed my proposal to use letters of the Czech alphabet for the above purpose (NATURE, April 29, 1922, p. 552)—a proposal which was opposed by Lord Gleichen and Mr. J. H. Reynolds and defended by Messrs. Druce and Glazunov (NATURE, November 11, p. 635, and October 14, p. 512)—I tried to find out the opinion of the Academy of Petrograd about this matter. At last, only recently, I have succeeded in obtaining from one member of the Russian Academy of Sciences a copy of a publication: "Memorial book of the Imperial Academy of Sciences for 1914—published March 20.—S.-Peterburg 1914." This contains on p. 180 a "Transcription of Russian Proper Names, approved by the Imperial Academy of Sciences (accepted in the Conference at the meeting of December 2/15, 1906)." To this table six notes are added containing rules concerning the cases in which

to use or not to use for transcriptions of vowels the Czech *j*, referred to in the table under (1)-(5).

а	б	в	г	д	е[2]	ё[5]	ж	з	и[3]	і	й
a	b	v	g	d	e, je	ë	ž	z	i, ji	i	j
к	л	м	н	о	п	р	с	т	у	ф	х	ц	ч
k	l	m	n	o	p	r	s	t	u	f	ch	c	č
ш	щ	ъ	ы	ь[4]	ѣ[2]	э	ю[1]		я[1]	о	ѵ
š	šč	–	y	ĭ	č, jě	e	ju, ĭu		ja, ĭa	f	i

For brevity's sake I do not translate the single notes.

I lived long enough in England to love the nation and appreciate its wonderful conservatism, and I quite understand that English geographers will scarcely give up the transcription once introduced by Lord Gleichen (of which I also possess a copy); yet a glance at the special Ordnance maps of countries of Central Europe, for example the excellent maps (1 : 75,000 or 1 : 25,000) of the late Austrian Empire, might convince everybody that the diacritic signs of half-a-dozen different languages are not a drawback in producing or using such maps even for military purposes.

Thus the nations outside Great Britain will have to choose between the mode of transcription defended by Lord Gleichen or the rules given by the Russian Academy of Sciences, which—up to this date having been unknown to me—happen to coincide with my proposal. BOHUSLAV BRAUNER.

February 1.

Herapath's Artificial Tourmalines.

I SEE that Prof. F. J. Cheshire (NATURE, February 3, p. 171), in his presidential address to the Royal Microscopical Society, urges "that the work of Herapath and others in the production of artificial tourmalines should be again taken up," and I wish strongly to support this hope. In my report in the War Office "Observations on Malaria" (1919) I showed that the Herapath test for quinine, especially as modified by Prof. W. Ramsden, is the most delicate test known for this alkaloid, and I feel certain that Herapath's method lends itself to many other applications. I have never found it to fail in the case of quinine, which I was able to detect even in dilutions of 1 in 15,000,000. M. NIERENSTEIN.

University of Bristol,
February 6.

The Mechanism of Audition.

IN connexion with the recent discussion in NATURE of the mechanism of the cochlea, and of the model of the cochlea designed by Mr. George Wilkinson (October 21, p. 559; November 11, p. 632), it seems well to point out another characteristic of hearing which will have to be taken into account in any comprehensive theory of audition. This is the abruptness of the changes which are found in the sensitivity of many ears when tested as a function of frequency. These are disclosed by the accurate determinations of the sensitivity-frequency characteristics of ears which have been made possible by the use of continuous ranges of pitch for acuity tests instead of the method of tests at discrete frequencies which has usually been used. A description of the apparatus used is given in an article soon to appear in the *Physical Review*. In some cases with apparently normal hearing people, changes as great as a factor of one thousand in the necessary intensity for audition are found with a change of pitch of a semitone, these occurring in connexion with depressions in the general level of sensitivity. Pictorially, this would seem to require the physical existence of a large number of elements each of which is concerned with the transmission of only a very narrow range of frequencies, these differentiated elements existing in the inner ear, in a possible cable from the ear to the brain, in the brain itself, or possibly in all three places, and of such a nature that the individual elements may be quite severely injured without seriously affecting neighbouring elements.

Spiranthes autumnalis.

IN NATURE of February 10, p. 185, Prof. Bower describes the finding of the orchid *Spiranthes autumnalis* near Carrbridge in the summer of 1921. I have to report the discovery of a single specimen of this orchid in the first week of September 1922, on Docharn Craig, a small hill (1250 ft.) four miles south-east of Carrbridge. The hill is under cultivation up to 1100 ft. on the southern side, but on the northern side there are the remains of a wood of magnificent wind-sown pines. The floor of the wood is covered with *Vaccinium* spp. (mainly *oxycoccus*), mixed in places with *Erica Tetralix* and *E. cinerea*: earlier in the season *Pyrola rotundifolia* and *Trientalis europea* were abundant. Only one plant of *Spiranthes autumnalis* was found, although the interest attaching to its unexpected discovery in this locality led to a careful search of the whole wood. The specimen was unfortunately lost in the transit to town, but when fresh it was quite unmistakable.

E. PHILIP SMITH.

46 Murrayfield Avenue,
Edinburgh, February 11.

PROF. BOWER'S letter in NATURE of February 10, recording the finding of *Spiranthus autumnalis* near Carrbridge, Inverness-shire, prompts me to record the presence of that orchid in the Island of Coll, Argyllshire.

Whilst surveying there in August 1921 my wife and I noted some half-dozen specimens. These, though undoubtedly of the genus Spiranthus, did not tally exactly with the description of *S. autumnalis* as given in Hooker's Flora, but the difference was not sufficient to make them a variety.

Unfortunately we have not preserved a specimen, but we were so surprised at the time at finding that species in Coll that we sent one specimen to a competent field botanist who confirmed our identification.

The Drayson Paradox.

THE writer of the first paragraph in the astronomical column of NATURE of January 20, page 94, refers to my pamphlet (Wm. Pollard and Co., Exeter, 1*s.* 6*d.*) in a way which might lead an incautious reader to suppose he had seen it, which evidently he has not, or he would scarcely speak of "wresting a few isolated observations to suit their preconceived views" in face of the statement on its nineteenth page that

"the *general consensus* of the stars supports the result given." A proof of that statement, a quantitative proof, will be found on pp. 42-44. I cannot encroach on your space to quote it here, but may briefly indicate its nature: P being the pole of the heavens and E the pole of the ecliptic, let P E C be a spherical triangle having E C 6°, P E 23° 27′, and P E C 174° 28′. Describe a small circle with C as centre and C P as radius: then will W, where E C produced cuts the circumference of the circle, be that spot where is situated the so-called "Apex of Solar Motion." The sides and angles given are not arbitrary but depend upon the rate of precession and of the decrease in the obliquity at the commencement of this century, as is shown on page 44 of the pamphlet.

This is a geometrical problem the significance of which your astronomical readers will readily appreciate. The facts it rests on are undeniable, and no alternative explanation to that suggested has hitherto been forthcoming. A. H. BARLEY.

Leppington House,
Hertford.

MR. BARLEY'S "incautious reader" would be quite correct in supposing that I had not only "seen" his pamphlet but read it carefully. It is not my practice to review works that I have not seen. I have, indeed, followed Draysonian publications with a melancholy interest from my youth up, and I cannot but regard them as an example of ingenuity misapplied.

Mr. Barley in his letter does not touch on the points I made (1) that if the proper motions of stars were due to any shift of the earth's axis, all the stars in a given direction would move together, and there would be no relative shift among them. But in examining photographs of the regions round stars with sensible proper motions (say Capella) the P.M. star is clearly seen to be moving among the faint stars in the background at practically the same rate as that given by the meridian observations. Indeed, Prof. Furuhjelm was enabled to detect a very distant companion to Capella by its sharing in its rapid motion relatively to the neighbouring stars. What is it then but "wresting" evidence to deny the reality of Capella's motion. (2) Mr. Barley denies the fact that the ecliptic is moving among the stars, and quotes Drayson as having tried to establish from the observations of Hipparchus that such motion did not exist. This to me appears another flagrant example of wresting isolated observations.

Hipparchus's results were liable to errors of several minutes of arc, whereas modern results are accurate to a second or thereabouts. Hence we can get a better result from 50 years using modern observations, than from 2000 years using those of Hipparchus. The modern observations show unmistakably that the ecliptic is shifting. Of course it is impossible to give all the evidence for this in the course of a letter, but I have arranged a small number of observations in a way that will show an unbiassed reader that such is the case.

The following table gives the North Polar Distance of the star 1 Geminorum as observed at Greenwich in different years, and also the North Polar Distance of the sun interpolated for the moment that its Right Ascension was the same as that of the star. It is to be noted that the N.P.D. of the star is referred to the mean equator of the year, that of the sun to the apparent equator affected by nutation; we can correct for this approximately by combining observations made about nine years apart when the nutation is opposite in direction and amount.

NORTH POLAR DISTANCE

Year.	Star.	Sun.	Star South	Mean.
1836	66° 44′ 7·71″	66° 32′ 39·05″	11′ 28·66″	11′ 22·18″
1844	66 44 5·51	66 32 49·42	11 16·09	
1855	66 44 1·70	66 32 39·92	11 21·78	
1876	66 43 55·85	66 32 39·54	11 16·31	11 5·04
1885	66 43 54·99	66 33 1·23	10 53·76	
1902	66 43 51·90	66 33 2·57	10 49·33	10 54·79
1911	66 43 51·65	66 32 51·40	11 0·25	

It will be seen that in sixty-one years the sun's path has moved southward relatively to the star 27·4″. The star itself is moving south 10·8″ per century (Boss), so this has to be added to the southward movement of the ecliptic. It will be understood that I give these figures merely to demonstrate the reality of the movement of the ecliptic, not to determine its exact amount, for which further refinements would be necessary. I chose a star near the solstitial colure (1) because difference of N.P.D. practically agrees with difference of latitude, thus saving reduction; (2) because this is the neighbourhood where the ecliptic is moving south most rapidly. I reiterate my advice to Mr. Barley to study the whole of modern astronomy of position, instead of confining himself to a few selected portions, which he interprets in a way that further study would show to be untenable.

THE WRITER OF THE NOTE.

The Naming of Elements.

SURELY the time has come to abandon the practice of attaching to elements fancy names arbitrarily selected by individuals. When names concerned nobody but a small clique in constant personal communication, and when they had nothing more important to record about an element than the personality of its discoverer, there may have been something to say for the system. Nowadays neither condition is fulfilled. Thousands are interested who have no means of expressing their opinion: and there is something definitely scientific to be said about elements. The new element was discovered as a consequence of a theory of the structure of the atom, and its discoverers should surely be glad to see a record left in the name that their discovery was no lucky fluke.

Dr. Aston, who has discovered at least twice as many elements as anybody else in the history of science, has set a good example; he has waived his right of naming, undoubted under the old dispensation. He has left them unnamed until a consensus of scientific opinion has established a scientific system of nomenclature. Will not others follow his lead? Until its isotopic constitution is discovered, let us simply call the new element 72.

NORMAN R. CAMPBELL.

Sarsen Stones.

REFERRING to the note on the discovery of the above near Maidstone, which appeared in NATURE of February 10, p. 195, may I direct attention to the fact that they occur in considerable numbers of large size, often in groups, near Faversham. The botryoidal concretionary surface-feature is frequently present, but what appears to be of greater interest is that many of the blocks are perforated by long, tubular holes suggestive of the work of marine annelids anterior to the consolidation of the rock. The gravel pits in this district yield large masses of sarsen occasionally. One stone I found recently weighs more than 2½ cwt., and can now be seen at the Twickenham Public Library. Full particulars appeared in the local press (*Richmond and Twickenham Times*, December 23, 1922). C. CARUS-WILSON.

Twickenham, February 19.

Poisoning by Illuminating Gas.

DURING the last few months much attention has been given in the public press to the question of the poisonous properties of illuminating gas and the risk to life which may be incurred if an escape of gas should take place in an ordinary dwelling. The only constituent of illuminating gas which has serious poisonous properties in this connexion is carbon monoxide.

Carbon monoxide has the property of forming a dissociable compound with the hæmoglobin of the blood just as has oxygen, but the affinity of carbon monoxide for hæmoglobin is about 240 times that of oxygen for hæmoglobin. The greater the extent to which the hæmoglobin becomes combined with carbon monoxide the less is its capacity to act as a carrier of oxygen between the lungs and the tissues of the body, and if sufficient of the hæmoglobin in the blood becomes combined with carbon monoxide the normal oxygen supply to the tissues must evidently be seriously affected. The effects produced by severe carbon monoxide poisoning are, in fact, those of slow or rapid asphyxiation.

If blood is exposed outside the body to air containing both oxygen and carbon monoxide the partition of the hæmoglobin between the two gases follows the laws of mass action, being determined by the relative partial pressure of the gases, allowance being made for the difference in their affinities. The air in the lungs with which the blood undergoes gaseous interchange contains in man about 14 per cent. of oxygen when he is breathing ordinary air. If human blood is saturated *in vitro* at body temperature with an atmosphere containing 14 per cent. of oxygen and $\frac{1}{240}$ of this proportion of carbon monoxide, *i.e.* 0·058 per cent., the hæmoglobin will finally become equally divided between the two gases, or 50 per cent. saturated with carbon monoxide and 50 per cent. with oxygen. If the concentration of oxygen is kept constant and that of carbon monoxide is varied the degree to which the hæmoglobin will become saturated with carbon monoxide is as follows:

IN THE PRESENCE OF 14 PER CENT. OF OXYGEN.

Percentage of carbon monoxide.	Approximate final percentage saturation of hæmoglobin with carbon monoxide.
0·015	20
0·03	33
0·06	50
0·12	67
0·17	75
0·23	80

If a person is exposed to ordinary air containing carbon monoxide the hæmoglobin in his blood will gradually become saturated with carbon monoxide just as in the experiments *in vitro*, and the degree of saturation will finally attain a steady value dependent on the precise concentration of carbon monoxide in the air that he is breathing. The symptoms that result will vary with the degree to which the hæmoglobin is saturated with carbon monoxide. If the hæmoglobin is 20 per cent. saturated the effects are practically unnoticeable to a normal healthy man, though headache may be caused by prolonged exposure or appear subsequently after reaching fresh air: even with 33 per cent. saturation nothing of a really serious nature occurs, though nausea and headache may be felt after some time, and transitory giddiness and confusion will occur after any short and severe muscular exertion. As the saturation of the hæmoglobin with carbon monoxide gets higher the symptoms rapidly become serious. With 50 per cent. saturation, giddiness, weakness and inco-ordination of muscular movement, failure of mental power, and diminution of acuity of vision and hearing are pronounced; slight muscular exertion causes palpitation of the heart and undue breathlessness, and will probably result in partial or complete loss of consciousness for a time. Such a degree of saturation must therefore be regarded as definitely disabling, but, so far as is known, it will not prove fatal. If the affected person is removed to pure air the mass influence of the oxygen will gradually expel the carbon monoxide from the blood, and the more urgent symptoms will subside fairly rapidly, though nausea, severe headache, and malaise may persist for many hours. With still higher saturations complete paralysis and unconsciousness will supervene, and the end may come with a painless death from sheer failure of the oxygen supply to the tissues of the body.

The minimum concentration of carbon monoxide that will prove fatal is not known with certainty, but the available evidence points to the conclusion that death will ensue after an exposure for several hours to air containing 0·2 per cent. of the gas. Much depends on the length of time that the blood has been highly saturated with carbon monoxide, for the longer grave shortage of oxygen is maintained the more serious is the damage to the tissues of the body, particularly to the nervous system, and the more difficult is recovery. Bearing this in mind it is not improbable that 0·15 per cent. of carbon monoxide in the air breathed might prove dangerous to life in the case of prolonged exposures.

Exposure to relatively high concentrations of the gas leads, of course, to rapid loss of consciousness and death, but in accidental cases of poisoning the concentration of carbon monoxide is, as a rule, comparatively low, and in these circumstances the onset of symptoms will be gradual though progressive, for the gas owing to its low concentration will diffuse but slowly into the blood and it will be long before complete gaseous equilibrium can be established between the blood and the air in the lungs. Herein lies a great danger, for so insidious is the onset of the symptoms that the person affected may not realise that anything is amiss until he has lost so much power in his limbs as to render it impossible to withdraw from the danger. With 0·1 per cent. of carbon monoxide in the air breathed a resting person will become disabled in about two hours and a half, with 0·2 per cent. in little more than a hour, and with 0·4 per cent. in about half an hour. The acceleration of the respiration and circulation by muscular exercise will greatly hasten the rate at which carbon monoxide is absorbed into the blood.

At present there is no legal limitation of the amount of carbon monoxide that may be supplied in ordinary

illuminating gas. The Departmental Committee on the Manufacture and Use of Water Gas, 1899, recommended that the Board of Trade should have the power to limit the proportion of carbon monoxide in illuminating gas to 12 per cent. or such higher value as should be considered safe. This recommendation was not, however, made statutory. The Departmental Committee on Carbon Monoxide, 1921, reported "that it is not necessary or desirable to prescribe any limitations of the proportion of carbon monoxide which may be supplied in gas used for domestic purposes," though a suggestion was considered that a limit of 20 per cent. of carbon monoxide might be imposed. Pure coal gas contains 6-8 per cent. of carbon monoxide, water gas contains about 40 per cent., and carburetted water gas about 30 per cent. Water gas is often added for economic reasons to pure coal gas, and the illuminating gas supplied to the public not infrequently contains a quite considerable proportion of carbon monoxide. Occasionally so much as 50 per cent. of water gas has been mixed with the coal gas, with the result that the illuminating gas has contained 20 per cent., or slightly more, of carbon monoxide. As a rule, however, the proportion of water gas is considerably lower than this, and some companies still continue to supply pure coal gas.

An escape of gas is likely to be noticed and quickly remedied during the daytime, but far greater danger arises at night when a person may fall asleep in an ill-ventilated bedroom without noticing that the tap of a gas jet has been accidentally left turned on, or disregarding as trivial an escape of gas from some faulty fitting. He may then be disabled before he has any warning of the danger, and when once disabled he may not be found till many hours have elapsed and it is too late to save him. From the experimental data recorded by Dr. J. S. Haldane in the report of the Water Gas Committee it is possible to calculate the concentration of carbon monoxide which will finally be attained in a room if there is a leak of gas into it, making the assumption that the carbon monoxide becomes uniformly mixed with the air. Even in the most unfavourable circumstances, when there are no special openings to admit of ventilation, there is always a considerable interchange of air through the walls, roof, and floor of any room. Even if the outside air is quite still a volume of fresh air equal to the cubic contents of the room will gain admission in 1·8 hours in a room of 500 cubic feet, in 2·3 hours in one of 1000 cubic feet, and in 2·9 hours in one of 2000 cubic feet, and these rates may be doubled if a strong wind is blowing or if the room is furnished with a fireplace the chimney of which is not blocked. Taking the most unfavourable case the following table shows what will happen in three different-sized rooms if there is a leakage of gas into these rooms at the rates respectively of 4 and 10 cubic feet per hour:

Capacity of room in cubic feet.	Carbon monoxide percentage eventually reached in the room when the illuminating gas contains the following percentages of carbon monoxide.				
A. Leak of 4 Cubic Feet per Hour.					
	5%.	10%.	15%.	20%.	30%.
500 . .	0·07	0·14	0·22	0·29	0·43
1000 . .	0·05	0·09	0·14	0·18	0·28
2000 . .	0·03	0·06	0·09	0·12	0·17
B. Leak of 10 Cubic Feet per Hour.					
	5%.	10%.	15%.	20%.	30%.
500 . .	0·18	0·36	0·54	0·72	1·04
1000 . .	0·12	0·23	0·34	0·46	0·69
2000 . .	0·07	0·15	0·22	0·29	0·43

The dotted lines mark the division into fatal and non-fatal percentages of carbon monoxide on the assumption that a concentration of 0·2 per cent. of carbon monoxide may prove fatal if maintained for several hours.

On testing the rate of escape of gas from an unlit gas-jet when the tap was turned on fully, four different burners chosen at random gave the following results. Under a gas pressure of 4 inches of water a properly regulated universal type of incandescent burner with inverted mantle passed about 4 cubic feet of gas per hour, and a Bijou burner of the same type about half that quantity. Under pressures of 1½ and 3 inches of water a No. 3 Bray flat flame burner passed about 6 cubic feet and 9 cubic feet per hour, respectively, and a No. 5 Bray burner about 8 and 11 cubic feet. Under the most adverse conditions, therefore, the risk of fatal poisoning would appear not to be very great in the case of escape from a single well-regulated incandescent burner so long as the proportion of carbon monoxide in the illuminating gas does not exceed 20 per cent., save in rooms of very small cubic capacity, though temporary severe symptoms might be caused. The real danger evidently lies in a leakage of gas considerably greater than that which might be obtained from such a burner. The pressure under which gas is supplied differs very greatly in different localities (under the Gas Regulation Act a minimum pressure of 2 inches water gauge has now to be maintained in the gas mains during the night), and an ordinary flat flame burner through which the rate of escape of gas will vary roughly as the square root of the pressure may clearly become a source of considerable danger if the tap should be accidentally turned full on. Some flat flame burners of improved type allow, however, much less gas to escape than the figures given above. Still greater risk attaches naturally to the grosser forms of leakage from unlit gas-rings, fractured pipes, accidentally disconnected unions and the like, provided that the escaping gas becomes sufficiently mixed with the air in the room. The Water Gas Committee found that with a large escape of coal gas the gas might collect mainly at the top of the room, and if the air in the room remained undisturbed it might be long before feeble convection currents could establish a fatal atmosphere at the level of a bed, but the case is, of course, quite different when the gas is rich in carbon monoxide.

It must be remembered that the table above intentionally depicts the most disadvantageous conditions for the occupant of the room. The majority of bedrooms possess a fireplace, and windows and doors often do not shut very tightly. The natural ventilation in a room might easily be double that on which the table is based without any special provision for ventilation, and the figures shown would then be halved. Under such conditions it would probably require a leak into a room of 1000 cubic feet capacity of 10 cubic feet per hour of gas containing 15 per cent.

of carbon monoxide to establish in the end a really dangerous atmosphere. That the risk in any case is bound to become far greater as the proportion of carbon monoxide in the illuminating gas is increased is evident. In the U.S.A., where much greater concentrations of water gas are used than in this country —indeed pure carburetted water gas is often supplied —the death rate from both accidental and suicidal gas poisoning appears to be far higher than in England. An article in a recent number of the *American Gas Association Monthly* conveys the impression that the gas companies are fully alive to the dangerous qualities of the gas that they distribute, for one of the New York Companies is stated to maintain in each of the districts it supplies a motor van with three crews working in eight-hour shifts ready to do ordinary repairs, and to proceed at any hour of the day or night when a case of gas poisoning is reported, not only to rectify the fault but also to resuscitate the victim of carbon monoxide if he can be reached in time, the crews having been specially trained for this purpose.

It is no use belittling the risks incurred by increasing the proportion of carbon monoxide in illuminating gas, but they should not be unduly exaggerated. It is evidently a case for striking a reasonable balance between the risk and the economic advantages of cheap light and heat for domestic purposes. The risk of accidental poisoning is greater the smaller the room in which an escape of gas occurs. The steady improvement in the housing of the poorer classes, the general use of more economical burners, such as incandescent burners, and the more widespread knowledge of the fact that illuminating gas does have poisonous properties undoubtedly justify a higher limit to be set to the concentration of carbon monoxide permissible in illuminating gas than was contemplated by the Water Gas Committee in 1899, but it may very reasonably be questioned whether the recommendation of the Carbon Monoxide Committee in 1921, that no limitation at all should be imposed by statute, is really justifiable. The report of the latter committee is certainly a most unconvincing document.

Imperial College of Science and Technology.

Opening of the New Botany Building (Plant Technology).

THE Imperial College of Science and Technology was founded to give advanced training not only in pure science but also in science in relation to industry. The close association of pure and applied science is exemplified in all the departments of the College, and under the direction of Prof. J. B. Farmer the botany department has been not the least conspicuous in the development of pure botany and of the various branches of applied botany which may be grouped together as plant technology. The department has for a number of years specialised in training men as economic botanists, and particularly for work in the great plantation industries of the tropics, such as rubber, cotton, sugar, etc. Ravages of disease caused by fungal and insect pests, and by other injurious agencies not yet so clearly defined, are particularly severe in these tropical industries, and without the control that science can supply their prosperity would be slight. A considerable proportion of the officers who are engaged in combating disease in tropical plantations have received their scientific training at the Imperial College.

By the rapid expansion of the work of the department in the direction of plant physiology, plant pathology, bacteriology, biochemistry, and plant technology generally, the accommodation provided by the present botany building became quite inadequate, though it was opened only so recently as 1914. Accordingly, an appeal for contributions towards the cost of an additional building was made to the members of the Rubber Growers' Association by Mr. Herbert Wright, an old student of the department and now chairman of the executive committee of the governing body of the College. Thanks to Mr. Wright's untiring zeal and energy and to his personal generosity, the magnificent sum of 30,000*l.* was raised.

FIG. 1.—New botany (plant technology) building, Imperial College of Science and Technology.

The new building was designed by Sir Aston Webb, and is a substantial and well-planned structure of five floors. The basement and ground floors are allocated

to biochemistry, and the first floor to the bacteriological side of plant pathology. The biochemical department is well fitted for modern work in biochemistry and includes, besides a laboratory for ordinary class instruction, a large and lofty general laboratory, a number of special research laboratories and private rooms, a laboratory for physical work, a balance room, and a machine room with grinding mills, presses, vacuum distillation apparatus, etc. The bacteriological laboratories are not only fitted for cultural work in microbiology, but also for chemical work in relation to fermentation by yeasts, moulds, and bacteria. On the first floor there is also to be a permanent rubber museum dealing especially with the diseases to which Hevea is subject.

The new building was opened on the afternoon of February 16. The ceremony was performed by the Duke of Devonshire, Secretary of State for the Colonies, Lord Buckmaster (chairman of the governing body) being in the chair. Mr. Herbert Wright, in an introductory speech, explained that the development of the department was due to the foresight and genius of Prof. Farmer, who many years ago realised how much could be done for the development of tropical industry by men with a proper training in such branches of botany as plant pathology and plant physiology. The response to the appeal to the Rubber Growers' Association was so encouraging because the members knew that the College had year after year trained men qualified to advise on vital problems relating to parasitic fungi, insect pests, and other problems of importance to tropical estates. The past pupils of the botanical department were scattered everywhere in the tropical regions of the Empire.

FIG. 2.—New botany (plant technology) buildings, Imperial College of Science and Technology. Main biochemical laboratory.

Prof. Farmer gave a brief survey of the work of the department, and stated that the number of students had increased from 78 in 1914–15 to 137 in 1922–23, a very large proportion of these being research students. This increase, together with the development of such branches of plant technology as biochemistry and bacteriology, had made urgent the further accommodation which the new building now provided. In the scientific education of plant technologists for tropical regions no attempt was made to give such men any detailed knowledge of tropical agriculture; that could only be satisfactorily done on the rubber estate, the sugar plantation, etc. What was aimed at was a thorough grounding in the fundamental sciences on which plant technology was based.

The Duke of Devonshire said that it gave him much pleasure to come to the College and open the new botany building. He well recognised the importance of tropical agriculture. In tropical Africa alone the area of the British dependencies was many millions of acres, with a population of thirty millions, practically all of whom were dependent on agriculture, which was, however, at present but imperfectly developed. Nothing could more surely contribute to the advancement of such dependencies than the application of science to the many problems of agricultural development. The Colonial Office, in establishing the Imperial Bureau of Entomology and that of Mycology, in founding the Imperial Department of Agriculture for the West Indies, and more recently the College of Tropical Agriculture in Trinidad, had shown a realisation of the importance of science in its application to the problems of the development of the agricultural resources of the Colonies.

A vote of thanks to the Duke of Devonshire was proposed by Sir Frank Swettenham (chairman of the Rubber Growers' Association) and was seconded by Sir Arthur Dyke Acland.

In connexion with the opening ceremony a large number of experiments and preparations illustrative of plant physiology and pathology were on view. One set of exhibits, which will form a permanent series, was arranged to show the diseases to which the rubber plantations are liable. It contained many large specimens which have been procured by skilled men and shipped direct from the plantations. It is safe to say that it forms the most complete exhibition of its kind that has ever been seen in Europe, and there is no doubt that it will be of considerable service to the new department for teaching purposes. Characteristic specimens of the obscure and much-dreaded disease, brown bast of rubber, were also displayed. The methods of investigating diseases were illustrated, and a large series of cultures of bacteria, fungi, and yeasts were on view.

A number of exhibits of physiological apparatus were also to be seen. These took the form mainly of instruments which recorded automatically (usually by an electrical device) the rate of some important vital process of the plant, such as growth, transpiration, change in the size of the pores (stomata) of the leaf, and so on. An apparatus for enriching with carbon dioxide at constant partial pressure the air supplied to growing plants was also included.

Obituary.

DR. C. P. GOERZ.

DR. CARL PAUL GOERZ, the founder of the well-known optical and instrument-making firm of C. P. Goerz, died at his home in the Grünewald, Berlin, on January 14, at the age of sixty-nine years. The record of his life is a remarkable one of industry and perseverance successfully exercised in the creation of a great establishment for the production of scientific apparatus of precision.

Although Dr. Goerz, to whom the honour of Doctor Ing. *honoris causa* was accorded by the Technical High School of Charlottenburg, had received no special academic scientific training, he realised the vital need for the exercise of scientific knowledge and research in such work as that to which he was devoted. His success is attributable to his commercial capacity, to his power of appreciating the value of the leaven of science in industry, and to his ability to utilise and encourage the efforts of those with whom he associated himself.

Towards the end of 1886 Dr. Goerz commenced business in Berlin as a small retailer of mathematical instruments, and later of photographic apparatus. In 1887 he engaged his first employee, the number of whom increased to many thousands during the recent war. The present firm dates nominally from 1888, when a small and simply equipped workshop was established in Berlin for the manufacture principally of photographic cameras. For the optical computation of the objectives he was fortunate in engaging the services of Carl Moser, who died in 1892.

Further progress resulted from the association of Paul Goerz with Ottomar Anschütz, whose pioneer work in the instantaneous photography of animal action had attracted much public attention. But the greatest advance in the fortunes of the firm is attributable to the introduction of the Goerz double anastigmat, designed by a casual applicant for scientific employment, Emil von Höegh.

Thereafter the progress was rapid. The present headquarters and well-equipped workshops were commenced in 1894. Numerous branches were established in foreign countries, and during the war a large mass-production factory was erected in the suburb of Zehlendorf. A separate works was devoted to the production of photographic film and kindred chemical work.

Realising the need for unrestricted supplies of optical glass, Dr. Goerz established on ground adjacent to his mass-production works at Zehlendorf the Sendlinger optical glass works, the origin of which can be traced through the laboratories of Steinheil at Sendlinger near Munich to the original glass works of Fraunhofer.

Dr. Goerz is survived by his second wife and by a daughter and two sons, the children of his first wife who died in 1897.

Through his death the German optical industry has lost a vigorous leader of striking personality, respected by all who were associated with him, and particularly by his many employees, in whose welfare he always exercised an active interest. J. W. F.

THE HON. R. C. PARSONS.

READERS of NATURE will have learned with regret of the death of the Hon. Richard Clere Parsons in London on January 26, in his seventy-second year. After a brilliant career at Trinity College, Dublin, where Mr. Parsons graduated in honours at twenty-two years of age, he was apprenticed to Messrs. Easton and Anderson, and it was during this period that his love of hydraulics developed and became the dominant factor in his life's work. In January 1875 he was asked by Mr. Anderson to make experiments upon centrifugal pumps, and the work culminated in the reading of a paper, entitled "The Theory of Centrifugal Pumps as supported by Experiments," before the Institution of Civil Engineers —a paper which gained him the Miller Prize. This was his first-fruits, and in his later work, both scientific and practical, he continued to be principally concerned with water-flow. Mr. Parsons read many other papers before the Institution, from which he received the Telford gold medal, the Manby premium, and the George Stephenson medal. His first important post was that of resident engineer of the South Hants Water Works; in 1880 he became a partner in the firm of Messrs. Kitson and Co., Leeds; seven years later he entered into partnership with the late J. F. La Trobe Bateman, F.R.S., and so commenced the consulting practice which he continued until his death.

Much of Mr. Parsons's work was carried out abroad; for example, the water supply and drainage of the city of Buenos Ayres, and the scheme which he prepared for the drainage of Petrograd. He held many important consultative appointments, and it was while acting in the capacity of engineer for the Water Works Company of Rosario that his inventive faculty exerted itself in producing an apparatus for automatically adding a coagulant to a water supply before filtration. To this he gave the name Tiltometer. It was followed by another invention called the Senfrot, for adding salt to water when under pressure.

Perhaps Mr. Parsons's most important invention was the Stereophagus pump introduced by him in 1911, and used for the pumping of sewage or water containing solid matter. In this, use is made of revolving blades, which cut up any solids, and thus prevent the possibility of choking. The description of this pump, and also of another, known as the Flexala, which was designed for dealing with fluids containing erosive substances, was given in a paper read before the Institution of Civil Engineers in 1919 entitled "Centrifugal Pumps for dealing with Liquids containing Solid, Fibrous or Erosive Matters."

Mention should be made of the interest which Mr. Parsons took in educational work. During his stay in Leeds he was connected with the development of the Yorkshire College, now the University of Leeds, and he was for thirty-three years connected with King's College, London, of which he was treasurer and vice-chairman. He was also, on the nomination of the University of London, a governor of the Imperial College of Science and Technology, and was a vice-president and manager of the Royal Institution.

MR. W. M. HUTCHINGS.

THE death of a well-known metallurgist, Mr. William Maynard Hutchings, occurred at Harrogate, at seventy-three years of age, on January 17. Mr. Hutchings' school-days were spent at a Moravian school on the Rhine, and he received his technical training in metallurgy and mining at Leipzig and Freiberg. After leaving the University he opened an assay office in Liverpool. Later he spent some years at the lead smelting works at Petrusola in Italy, and after a short period in South Wales became manager of Walker Parker and Co.'s Deebank Lead Works at Bagillt, North Wales, where he replaced the older Pattinsonian process by the then comparatively new Parkes process. In 1889 Mr. Hutchings joined the firm of Messrs. Cookson and Co., Ltd., at Newcastle, as their chief metallurgist and technical manager. In conjunction with the late Mr. Norman Cookson, he designed and installed a large Parkes desilverising plant, which was at the time a model of efficiency. He also introduced for them the first chamber white lead works in this country, which he operated with great success. He retired from active duties in 1915, but held a consulting post with this firm till the time of his death.

Throughout his busy life Mr. Hutchings found time to carry out investigations in other branches of science, and his numerous and lengthy papers on the petrology of shales, clays, and slates published in the *Geological Magazine* created great interest, and are evidence of his active mind and patient capacity for research. He also contributed frequently to several scientific periodicals, and at one time contributed a regular column to *Engineering*. He was an original fellow of the Institute of Chemistry and some time member of the Society of Chemical Industry.

Mr. Hutchings was essentially a strong man, thorough in all his work, a distinguished metallurgist, and a fearless advocate of his own convictions. He was of a retiring disposition, but a lover of Nature, and a notable characteristic was his intense love of animals.

WE regret to announce the following deaths:

Rev. J. C. P. Aldous, author of "An Elementary Course of Physics," and formerly chief naval instructor of the cadets in H.M.S. *Britannia*, on February 18, aged seventy-three.

Prof. E. E. Barnard, professor of practical astronomy in the University of Chicago, on February 6, aged sixty-five.

Prof. J. W. Caldwell, emeritus professor of chemistry in Tulane University of Louisiana, on January 2, aged eighty.

Dr. J. A. Elliott, professor of plant pathology in the University of Arkansas and pathologist in the Arkansas Agricultural Experiment Station, on January 18.

Dr. James Gow, formerly headmaster of Westminster School and author of "A Short History of Greek Mathematics," on February 16, aged sixty-nine.

Prof. S. Günther, emeritus professor of geography in the Technical High School of Munich.

Prof. S. S. Keller, head of the department of mathematics of the Carnegie Institute of Technology, on January 12.

Mr. F. J. Lloyd, agricultural chemist, for many years connected agricultural and dairy societies, on February 8, aged seventy.

Dr. F. Neesen, professor of physics in the Military Technical Academy of Berlin, and known for his work on the determination of trajectories by a photographic method, aged seventy-three.

Prof. W. N. Parker, emeritus professor of zoology at the University College of South Wales and Monmouthshire, Cardiff, on February 22, aged sixty-five.

Dr. Terano, director of the Aeronautical Research Institute in connexion with Tokyo Imperial University and formerly professor of naval architecture in the Engineering College of that University, on January 8, aged fifty-four.

Current Topics and Events.

THE council of the Royal Society has recommended for election into the society this year the following fifteen from the list of candidates:—Dr. E. D. Adrian, Dr. W. Lawrence Balls, Prof. Archibald Barr, Prof. C. H. Desch, Prof. E. Fawcett, Prof. F. Horton, Dr. R. T. Leiper, Prof. J. W. McBain, Prof. J. J. Rickard MacLeod, Dr. G. A. K. Marshall, Sir Douglas Mawson, Dr. W. H. Mills, Dr. J. S. Plaskett, Prof. H. R. Procter, and Prof. W. Wilson.

THE official opening of the new research laboratories of the General Electric Co., Ltd., at Wembley on February 27 was an interesting event. It is probable that this is much the largest industrial research laboratory erected by any firm in this country. The buildings have a total floor space of more than 80,000 sq. ft., and the tour planned out for visitors, comprising a passage through all the laboratories and workshops, involves a walk of something like three miles. There is a well-equipped library, and an organised system of abstracting and recording papers for reference has been devised. Throughout the building, pipes carrying gas, compressed air, a vacuum service, etc., have been installed, the taps being painted in distinctive colours. A feature is the arrangement whereby pipes and electric cables traverse a gallery at the top of the building so that none are carried under the floor, the outlets descending from the ceilings. In addition to the large number of rooms devoted to different sections of research work, there are wood and metal workshops, and a small experimental factory where new types of lamps can be made and tested on a small scale, so as to eliminate all manufacturing difficulties before manufacture in bulk is attempted. In these days, when demand for economy plays such an important part in the programmes of manufacturing concerns, it is interesting to note this enterprising departure, which will doubtless be well repaid.

A CONSIDERABLE amount of attention has been devoted in the daily Press to a paper dealing with various alleged dangers to eyesight of electric light, read by Mr. A. E. Bawtree before the Royal Photographic Society on February 13. One of the points raised, the high intrinsic brilliancy of filaments, has

a certain degree of justification, and various members of the Illuminating Engineering Society who were present at the discussion agreed that electric lamps, in common with other modern illuminants, require proper shading. The effects of ultra-violet light have been thoroughly studied, but it is now generally agreed that the possibility of injury to eyesight being caused by the small proportion of such radiation present in incandescent lamps is remote. Certainly the matter does not deserve to be regarded with alarm. Moreover, photographers should be well aware that the amount of ultra-violet light in natural light is considerably greater than that in most artificial illuminants. Of other problematical dangers such as "X-ray, electron, and undiscovered emanations," the author could present no confirmatory evidence and they were not regarded with any concern by the audience, the speakers dissenting from most of his suggestions. The matter is of interest as furnishing one of those cases in which alarmist statements are indiscreetly published in the daily Press, and relatively small difficulties, easily overcome by reasonable care, are magnified. A little prior consultation with experts in such cases would enable editors to avoid giving publicity to unconfirmed statements which are liable to cause misapprehension on the part of the public.

AMONG the resolutions adopted by the council of the American Association for the Advancement of Science at the December meeting at Cambridge, Massachusetts, is one referring to recent attempts in various parts of the United States to prohibit the teaching of evolution as applied to man. The council asserts its position and that of the Association with its 11,000 members clearly and emphatically in the following resolution: "(1) The council of the association affirms that, so far as the scientific evidences of the evolution of plants and animals and man are concerned, there is no ground whatever for the assertion that these evidences constitute a 'mere guess.' No scientific generalisation is more strongly supported by thoroughly tested evidences than is that of organic evolution. (2) The council of the association affirms that the evidences in favour of the evolution of man are sufficient to convince every scientist of note in the world, and that these evidences are increasing in number and importance every year. (3) The council of the association also affirms that the theory of evolution is one of the most potent of the great influences for good that have thus far entered into human experience; it has promoted the progress of knowledge, it has fostered unprejudiced inquiry, and it has served as an invaluable aid in humanity's search for truth in many fields. (4) The council of the association is convinced that any legislation attempting to limit the teaching of any scientific doctrine so well established and so widely accepted by specialists as is the doctrine of evolution would be a profound mistake, which could not fail to injure and retard the advancement of knowledge and of human welfare by denying the freedom of teaching and inquiry which is essential to all progress."

THE association of Sir Christopher Wren with the Old Ashmolean building at Oxford, to which Mr. R. T. Gunther directs attention in a letter published in our correspondence columns, is of particular interest at the present time, on account of the celebration of the bicentenary of Wren's death. Mr. Gunther's suggestion, that the upper rooms of the building should be used as a science museum, has received the support of practically all the leading members of scientific departments of the University, as well as of others. If this proposal is approved, it is hoped that the valuable collection of old astronomical and other scientific instruments offered by Mr. Lewis Evans to the University will be housed in the Old Ashmolean building, which, should Mr. Gunther's views be correct, will thus be restored to its ancient purpose.

H.R.H. THE PRINCE OF WALES has accepted the presidency of the Empire Forestry Association, and is presiding at the Association's annual meeting at the Guildhall at 3 P.M. on March 2. At this meeting the new council of the Association will be elected, consisting of 45 members—9 for the United Kingdom, 10 for the Dominions, 2 for India, 6 for the Crown Colonies and Dependencies, and 18 for affiliated societies—nine of these representing Overseas associations. The Prince of Wales is proposing the adoption of the report of the Empire Forestry Association, which has made remarkable progress since it was formed as an outcome of the post-war Imperial Forestry Conference. The Association is promoting a permanent exhibition of Empire commercial timbers in London, and will play an important part with regard to the timber section at the British Empire Exhibition in 1924.

A SPECIAL exhibit of abnormal growths taken from trunks, branches, and roots of trees and shrubs has been arranged in Museum IV. at Kew Gardens. The specimens include burrs, witches' brooms, deformed leaves, contorted stems, fasciated shoots, deformed roots, and other items. In some instances the deformity is due to injury at an early period of the plant's life; in others (as in fasciation) it may be caused by luscious growth, while deformed leaves may sometimes be a reversion to a former type. Witches' brooms are usually caused by irritation set up by fungus or insects. They are very common on birch, but occur on many kinds of trees. Burrs on trunks may follow a blow on the bark or the punctures of insects. Burrs are often very large, and the wood is prettily marked. It is in demand for furniture and cabinet work, and often commands a high price. Curved trunks (as in the pine stems exhibited) are brought about by the tunnelling of the larvæ of a small moth. Irregular annual rings are often caused by a tree being fully exposed to sun and air on one side and crowded on the other. Roots are often deformed by growing in gravel beds or between the bricks of walls, whilst the development of aerial roots on trees and shrubs may be due to an injury or to excessive moisture.

AN address on "Biological Contributions to Sociology," delivered by Prof. J. Arthur Thomson before the Sociological Society on February 20, Prof. G. Elliot Smith in the chair, raised a number of questions of wide interest. Knowledge of what may be termed the natural history of man is closely related to the study of social activities and changes, and it should be used to promote the healthy growth of civilised society. Among biological subjects which have a direct bearing upon this development are heredity and environmental influence, variation as the raw material of possible evolution, the relation of individuation and reproduction, population problems, the results of inbreeding and outbreeding in man, the selective influence of disease, and the preservation of the physically unfit in civilised life. As regards the physical characteristics of man, natural selection has ceased to operate in modern society, and the weak and morally or mentally deficient are encouraged to live at the expense of the strong. Society itself will eventually have to decide whether it will continue to promote the reproduction of the unfit or adopt measures of artificial selection with the object of eliminating them. Man can be the master of his own destiny, and is not altogether the creature of circumstances, as are other natural species. The race ought, therefore, to look to scientific guidance for human growth not only towards individual fitness but also towards a higher human perfection.

AT the Royal Asiatic Society on February 13, Mr. E. J. Holmyard delivered a lecture on Arabian alchemy and chemistry, in the course of which attention was directed to the large amount of material available in manuscript form in the libraries of Europe, especially Constantinople, and in Cairo. Mr. Holmyard also expressed the view that it was probable that the laboratory note-books of the chemists of Islam might prove, if they could be found, of at least equal importance with their more famous books. The question of Geber was considered, and some lantern slides, showing typical forms of apparatus, were exhibited. In the discussion which followed, Prof. E. G. Browne laid stress on the need for a thorough and adequate study of the development of chemistry in Islam. Dr. C. Singer disagreed with the lecturer's statement that the Arab chemists kept their chemistry free from astrology, and said that a belief in astrology was a normal part of the mental equipment of all educated men in the Middle Ages. Mr. Robert Steele showed the connexion between Arab chemistry and medieval European chemistry, and Prof. J. R. Partington brought forward further evidence in favour of Mr. Holmyard's views that Berthelot's arguments against the identity of Geber and Jābir ibn Ḥaiyān were unsound. Dr. Gaster pointed out the importance of Berthelot's work on the Greek alchemists, and Mr. H. S. Redgrove suggested that it was rash to assume that the mystical alchemical verse of Khālid ibn Yazīd had no practical meaning.

THE annual general meeting of the Institution of Heating and Ventilating Engineers was held on February 6, and Mr. John Watson was elected president for the year. In his presidential address he stated that they might be proud of the progress of the Institution, in membership and influence, during the twenty-five years of its existence. Several Government departments have representatives on the Institution's committees, showing that its influence is extending. Referring to the education of the engineer, Mr. Watson considered that the facilities now offered are much in advance of anything previously available. At the age of 21 or 22 years, any intelligent youth who has followed the prescribed 6-years course suggested in "Advice to Intending Students" would be well informed in general knowledge of elementary engineering science, and in the basic facts of heating and ventilation. Mr. Watson also referred to some technical matters. The question of super-power stations for the supply of cheap motive power had been discussed by the district heating committee in conjunction with a committee of the Institution of Electrical Engineers. The use of condensing engines in existing stations led to an enormous amount of heat being carried away in the condensing water, whereas by using some of these stations as combined heating and power stations, and utilising the exhaust steam for heating and hot water supply to buildings in the vicinity, something like 50 per cent. of the heat content of the fuel would be realised in useful work, instead of perhaps 12 per cent.

DR. W. H. MAW, president of the Institution of Civil Engineers and past-president of the Institution of Mechanical Engineers and of the Royal Astronomical Society, has been awarded the Bessemer gold medal of the Iron and Steel Institute. The medal was founded by Sir Henry Bessemer in 1873, and is awarded annually to any member or non-member of the Institute who may be (1) the inventor or introducer of any important or remarkable invention, either in the mechanical or chemical processes employed in the manufacture of iron or steel; (2) for a paper read before the Institute, and having special merit and importance in connexion with the iron and steel manufacture; (3) for a contribution to the Journal of the Institute, being an original investigation bearing on the iron and steel manufacture, and capable of being productive of valuable practical results. The medal may also be awarded for work not coming strictly under the foregoing definitions, should it be considered that the iron or steel trades have been or may be substantially benefited thereby. A diploma accompanies the award of the medal, in which it is formally stated that the award is "for eminent services in the advancement of metallurgical knowledge," or, alternatively, "for eminent service in the advancement of the application of iron and steel."

A DINNER to celebrate the twenty-fifth anniversary of the foundation of the Röntgen Society will be held on Thursday, March 15, at the Hotel Cecil, Strand, London, W.C.

THE annual meeting of the Royal Society for the Protection of Birds will be held at the Middlesex Guildhall, Westminster, S.W., on Wednesday, March 7.

MAJOR-GENERAL SIR WILLIAM B. LEISHMAN has been appointed Director-General, Army Medical Service, in succession to Lieut.-General Sir T. H. J. C. Goodwin.

THE degree of doctor of laws *honoris causa* has been conferred on Sir Frederic Kenyon, director and principal librarian of the British Museum since 1909, by Princeton University, New Jersey.

AT the Bristol Museum, according to the report for the year ending September 30, 1922, Mr. F. G. Pearcey has built up in an exhibition case the representation of a living coral reef. "A collection of typical reef corals has been covered with a thin gelatine layer, coloured as true to the living coral as possible, and arranged in natural fashion upon a modelled sea-floor, together with crustacea, mollusca, sea-urchins, and fishes." It sounds simple, but needs in the artist that knowledge of actual reef conditions which Mr. Pearcey possesses, thanks to his voyages in the *Challenger* and other exploring ships.

AMONG the books to be published during the spring and summer this year by the Clarendon Press and the Oxford University Press are: Vol. 5 of the translation of Suess's "The Face of the Earth," being the index of subjects and of persons and places; "The British Coal-mining Industry during the War," Sir R. A. S. Redmayne, comprising chapters on the pre-control period—1915–16, the period of government control—1917–18, de-control—1919–21, general survey of the coal-mining industry of the United Kingdom during the period 1914–21 and appendixes; "The Legacy of Rome," edited by C. Bailey, with the following contributions: Religion and Philosophy, C. Bailey, Family and Social Life, H. Last, Literature, J. W. Mackail, Language, H. Bradley, The Science of Law, F. de Zulueta, The Conception of Empire, E. Barker, Roman Architecture and Art, G. McN. Rushforth, Science, Dr. C. Singer, Administration, H. Stuart-Jones, Communications and Commerce, G. H. Stevenson, Agriculture, W. E. Heitland, and Engineering, G. Giovannoni; "Makers of Science," I. B. Hart, in which an attempt is made to present a survey of the broader movements in the history of the physical and mathematical sciences from Greek days to the present time.

Our Astronomical Column.

PARTIAL ECLIPSE OF THE MOON.—A partial eclipse of the moon will occur during the morning hours of March 3, and may be well observed if the atmosphere proves favourable. The moon will enter the denser shadow of the earth at $2^h\ 28^m$ A.M., the middle of the eclipse will be at $3^h\ 32^m$ A.M., and our satellite will emerge from the shadow at $4^h\ 36^m$ A.M. The fainter shade or penumbra will also involve the moon between $1^h\ 13^m$ A.M. and $5^h\ 51^m$ A.M. The northern or upper region of the disc will be obscured, and if we regard the whole surface as equal to 1·0 the proportion eclipsed will amount to 0·38, or nearly two-fifths. This eclipse is a return of that of February 19, 1905, when the magnitude was about three-tenths.

The cycle of recurrences in eclipses is equal to 18 years and 11 days and was discovered by the Chaldæans, who named it the Saros. It enabled the ancients to foretell the return of these phenomena with tolerable accuracy.

THE ATMOSPHERE OF VENUS.—Mention has been made in this column (May 6, 1922, p. 592) of the result obtained by Prof. St. John and Mr. G. B. Nicholson, at Mt. Wilson, demonstrating the absence of the lines of water-vapour and oxygen in the spectrum of Venus. A paper by them in *Astrophys. Journ.*, December 1922, gives full details of the investigation, with beautiful reprints of the spectra, which are arranged to make the Doppler displacement of the solar lines in the spectrum of Venus clearly visible, while it is absent for the water-vapour band, showing its telluric origin. It is stated that the spectra confirm Prof. Slipher's result that fifteen days seem to be an inferior limit for the period of rotation of Venus.

A review is given of former results. Vogel, Scheiner, and Arrhenius all concluded that water-vapour is present on Venus from the apparent strengthening of its spectral bands; but obviously the use of the Doppler principle with a high dispersion is far more decisive. It is concluded that the quantity of oxygen in the atmosphere of Venus can scarcely exceed a thousandth of that in our own, or it would have been detected.

The authors quote the suggestion of Arrhenius that the oxygen in our atmosphere may have resulted from plant life, so that if Venus had no organisms on it oxygen would not be present in its atmosphere. Proceeding to speculate on the conditions on the planet, they consider that the slow rotation would be likely to cause violent air circulation, owing to the great difference of temperature between the day and night hemispheres. It is supposed that the rotation, though slow, is not so slow as to put one hemisphere in perpetual night. The absence of water would make the ground very dusty, and high winds would raise dense clouds of it. It is suggested that this is the nature of the Venus clouds. According to Prof. Russell their albedo is less than that of our clouds. It is suggested that direct photographs through violet and infra-red filters, as used by Prof. R. W. Wood on Jupiter and Saturn, would give information about these clouds, and might even reveal the surface below in regions where they were thin.

THE RADIAL MOTIONS OF STARS OF TYPE N.—This type (Secchi's Type IV.) consists of red stars with carbon bands. Lick Observatory Bulletin No. 342 contains a study of the velocities of twenty-five of these stars in the line of sight by J. H. Moore. Twenty-three of these stars have well-determined proper motions, and a correlation of these with the radial velocities enables the mean parallax of the group to be determined. Three different methods of treating the data give the closely accordant values of the latter 0·0032″, 0·0028″, 0·0031″. The mean apparent magnitude of these stars at maximum is 6·1, which implies a mean absolute magnitude of −1·5, in good agreement with the value −1·3 found by Luplau-Janssen and Haarh from the proper motions alone. This gives confidence in the result.

It appears that these stars are giants, in an early stage of their career as stars. Till the Giant and Dwarf Theory obtained currency, the red variable stars were generally looked on as expiring suns, and compared to a candle flickering in its socket before extinction, but this new research combines with many others to show that this view is incorrect.

Research Items.

PSYCHOLOGY IN ENGINEERING.—In his Sidney Ball memorial lecture (Scientific Management and the Engineering Situation, Barnett House Papers, No. 7, Oxford University Press, 1922. Price 1s.), Sir William Ashley discusses the much debated problem of scientific management, with special reference to the engineering trade. He reviews its beginning in America, its development there, and the interest aroused in it in this country. He points out that, as it has arisen in the engineering trade, it bears the marks of people accustomed to think in terms of the exactly measurable, engineering being largely a matter of exact formulæ. Unfortunately for the mechanist, the human being is quite frequently influenced by motives which defy exact measurement. Aiming at increasing output and thereby diminishing the cost for each unit of work, it was attempted by time and motion study and a bonus system to settle the problem of wages. It has, however, introduced more complications to an already complicated problem, and just where it leaves the domain of mechanics to enter that of psychology, it breaks down. English psychologists criticise the so-called scientific management, not because it calls itself scientific, but because it is not sufficiently scientific. The application of science to industry is valuable, but it is not scientific to apply the principles of one science to problems belonging to another of a quite different order.

FLEAS AND PLAGUE IN INDIA.—One of the most striking features of the prevalence of plague in India is the relative immunity of Madras compared with, for example, Bombay or the Punjab. The Advisory Committee for Plague Investigation examined the problem at length, but failed to find any satisfactory explanation. It was believed at that time that the prevalent rat flea all over India was *Xenopsylla cheopis*. Röthschild, however, afterwards found that under that identification three very closely allied species—*X. cheopis*, *X. astia*, and *X. brasiliensis*—had been confused, and Hirst pointed out that the distribution of plague in India and Ceylon corresponded well with the hypothesis that the real *X. cheopis* was alone an effective transmitter of the disease. He now reports (*Indian Journal of Medical Research*, vol. x., 1923, p. 789) a full series of experiments confirming his earlier work, and showing that *X. astia*, the prevalent rat flea in Madras, will carry plague from one animal to another only with much more difficulty than *X. cheopis*, the rat flea of Bombay. Details of plague epidemics in Colombo, where plague has never become widely spread and where the fleas are mostly *X. astia*, with a few *X. cheopis*, bear out his thesis in a striking manner. It seems as if a considerable advance has been made in the epidemiology of plague which illustrates the fundamental importance of systematic zoology in these problems.

EFFECTS OF THE CONTIGUITY OF ORGANISMS.—In a series of experiments on the influence of density of population on longevity in the fly Drosophila, R. Pearl and S. L. Parker show (*American Journal of Hygiene*, vol. iii., 1923, p. 94) that the optimal density for duration of life is not the minimal density The mean duration of life increases with increase of density of population up to a certain point, and afterwards, as would be expected, declines. Thus, starting with about 2 flies per ounce bottle the average life is 28 days, which increases rather rapidly to about 40 days with 50 flies per bottle, declines again to 28 with a density of about 90, and to 17 and 13 with densities of 150 and 200. This favouring effect of organisms on one another recalls the observations of T. B. Robertson (*Biochemical Journal*, vol. xv., 1921, p. 612), who found that the rate of asexual multiplication of the infusorian Enchelys was much greater if the culture contained two individuals to start with than if only one was present. It is too familiar to most bacteriologists that the dispersion of a few bacteria in a large volume of culture liquid will often fail to give a successful growth which is obtained with certainty if the same number of organisms is sown in a small quantity of medium. All this suggests a general proposition that contiguity to like individuals is, up to a certain point, favourable to the life of organisms.

CORK FORMATION.—In a continuation of the useful physiological studies in plant anatomy carried out at the University of Leeds, Prof. J. H. Priestley and Miss L. M. Woffenden (*New Phytol.*, vol. 21, No. 5) have made a study of the causal factors in cork formation. A causal sequence can be traced both in the formation of wound cork and leaf scars, as well as in the natural internal origin of a cork layer. A parenchyma surface is first blocked by suberin deposits in presence of air. This is followed by the accumulation of sap at the blocked surface, and this in turn gives rise to the development of a phellogen or cork cambium in the area involved. In the absence of air, a meristematic zone may be artificially produced without the formation of cork in the cell walls.

GROWTH AND MATURATION OF THE SUGAR CANE.—Dr. Kuyper has described the physiology of sugar formation, and the methods used in Java to harvest the canefields at the exact moment of highest maturity in "The Formation of Sugar and the Ripening in Sugar Cane" (Suikervorming en ryping by het suikerriet), Archief voor de Suiker-industrie in Nederlandsch Indië, 1922, 2e deel blz. 195-321, Mededeelingen No. 5. Cultivation is so directed that the fullest use is made of the available light, and in this connexion the author discusses the questions of the optimum distance between the plants and rows, the effect of tying up the canes as a preventive against lodging, the influence of yellow stripe disease upon sugar production, and the relation between cellulose formation and sugar content. In Java the process of ripening of sugar cane is carefully watched by means of analyses of samples taken regularly every two or three weeks. The course of maturity can be judged by the relation between total solids and the quotient of purity (Brix and RQ) in the different parts of the stalk; the glucose ratio changes in a way which is the reverse of that seen in the percentage of available sugar. It has been proved that the time of planting and the age of the cane have much influence upon the maturation process, as if climatic conditions are favourable the sugar content of fields of different ages may reach almost the same final percentage, whereas under unfavourable conditions the late planted canes will not be so rich in sugar. Maturing is found to progress most regularly in places in which the rainfall is very low during the milling season, but where the soil contains sufficient moisture to prevent the cane from dying without permitting further growth to occur.

OCEANOGRAPHY OF THE SOUTHERN OCEAN.—A note by Commander F. A. Worsley in the *Geographical*

Journal for February gives some account of the hydrographical work of the *Quest* expedition. Thirty-two soundings were taken in the Southern Ocean. The first series was from a point 500 miles east of the South Sandwich Group to about lat. 60° 45′ S., long. 4° E., and then to lat. 69° 18′ S., long. 17° 11′ E. The position and details of the soundings are not given, but it would appear that water of practically 3000 fathoms was crossed in the supposed "deep" in the Biscoe Sea. Shoaling water towards the south, practically where Bellingshausen made his southern attempt in 1820, confirmed that navigator's belief in the occurrence of land not far off. A depth of 1089 fathoms might occur within 50 miles of the Antarctic continent. From this point an irregular line of soundings was carried westward across the mouth of the Weddell Sea towards Elephant Island. These confirmed the discoveries of the *Scotia* and *Deutschland*, which showed the Weddell Sea to be approximately 2500 fathoms in depth. No soundings were taken between Elephant Island and South Georgia, and only three were taken between South Georgia and Tristan da Cunha. None appears to have been taken in the uncharted waters to the east of the South Sandwich group. It is most unfortunate that heavy weather prevented oceanographical work exactly in those areas where the gaps in knowledge are widest. A search for a reported reef 350 miles E. by N. of Tristan da Cunha showed that it does not exist. The paper also contains a new map of Gough Island and some additional surveys in South Georgia.

OIL EXPLORATION IN NEW SOUTH WALES.—The Federal Government of Australia recently offered a reward of 50,000*l.* for the discovery of commercial deposits of petroleum within the continent, in order to encourage private enterprise in prospecting. Not content with this, the New South Wales Government has made a further offer of 10,000*l.* for the discovery and production of 100,000 gallons of natural mineral oil within the State, and so that such enterprise, if undertaken, should be carried out with at least a technical chance of success, a blue-book has been prepared by the Geological Survey of that State, which discusses petroleum and natural gas and the possibilities of their location within its confines. The publication is a credit to all concerned, but more particularly to its author, Mr. Leo J. Jones, who, writing primarily for the non-technical public, has set forth the principles of oil production in a commendably lucid manner. By following the text of the first five chapters of the pamphlet carefully, no ultimate failure can be set down to ignorance, and the "wild-catter," if unsuccessful, can reasonably plead ill-luck. The two concluding chapters review past operations for locating oil-pools in New South Wales and discuss the possible areas awaiting exploration. A complete stratigraphical succession for the State is quoted, and forms the basis of a brief survey of the oil potentialities of each formation. In the summary, however, we are acquainted with the official opinion regarding future oil possibilities, two extracts from which read as follows: "The prospects of obtaining commercial supplies of oil in New South Wales are by no means bright . . .," and again ". . . New South Wales will have to depend for its oil supplies, not upon deposits of crude petroleum, but upon the mining and distillation of oil shales . . ." already known to occur extensively in the state; with which observations we are in entire agreement. It would thus seem that the New South Wales Government is reasonably safe in offering the reward quoted, and, for that matter, the Federal Government is probably in a similar position.

METEOROLOGY IN MYSORE.—The twenty-ninth annual report for 1921 and a separate report on rainfall registration in Mysore for 1921, prepared under the direction of Mr. N. Venkatesa Iyengar, meteorological reporter, have recently been published by the Mysore Government. The annual report contains data for the four observatories, Bangalore, Mysore, Hassan, and Chitaldrug. Monthly means for the several elements are compared systematically with the respective normals for 29 years. Annual means of temperature at the four observatories differed by rather more than 4° F., Bangalore being the coldest with 69°·2 F. and Chitaldrug the warmest with 73°·6 F. Rainfall for the year was greatest, 36·62 in., at Bangalore, which is 1·43 in. more than the normal, the least, 24·37 in., at Chitaldrug, which is 0·50 in. less than the normal. According to the report on rainfall registration, rain is measured at 226 stations, the mean for the State being 36·19 in. against an average of 36·10 in. The greatest rainfall in 24 hours was 14·60 in. at Agumbi in the Shamoga District on July 30. The two heaviest falls of rain in 24 hours during 1921 are given for each of the rainfall stations. Percentage of the rainfall is given for each season in each district and for the State as a whole. For the State in the cold weather period, January and February, the percentage of the normal was 238; in the hot weather period, March to May, it was 3 per cent. deficient; in the south-west monsoon period, June to September, it was 5 per cent. deficient; and in the north-east monsoon, October to December, it was 11 per cent. in excess. The rainfall is given for the several river basins, and the departure from the normal. The detailed results are of considerable value to the world's meteorology.

CONCENTRATION OF MINERALS BY MULTIPHASE MAGNETS.—The problem of the utilisation of multiphase currents for the separation of minerals from ore continues to be developed by Mr. W. M. Mordey. An important paper on the subject, which he read in December 1921 before the South African Institution of Electrical Engineers, was dealt with in an article by Prof. Truscott, of the Royal School of Mines, in NATURE of April 29 last year. Experiments illustrating the physics of the method were shown last summer at the conversaziones of the Royal Society, and were repeated with some extensions on the occasion of the Silvanus Thompson Memorial Lecture at Finsbury Technical College on February 1. Meanwhile, in the Bessemer Laboratory of the Royal School of Mines the process is assuming a character approaching practical requirements. A stream of "pulp," consisting of crushed mineral in water, is passed down a launder, under which is placed a multiphase magnet. The magnetic field causes the mineral constituents to move gradually to one side of the stream, leaving the gangue on the other side. In this test the material principally made use of is an ore of Norwegian specular hæmatite, a crystalline oxide of iron, which, being almost *non-magnetic*, is not amenable to treatment by ordinary magnetic separators. Under the influence of the multiphase magnet, the particles of this material can be seen moving steadily across the stream, from one side of the launder to the other, in a way that will be understood by those who have witnessed these experiments with dry materials. The test has also been carried out with an ore of magnetite. This powerfully *magnetic* material is, for the most part, held stationary over the poles of the multiphase magnet; but when the field is reduced in strength, its action resembles that of specular hæmatite, *i.e.* the concentrate forms on one side of the stream, and the gangue is washed down on the other.

The Unit Activity of Animal Organs.

ONE of the most remarkable features of the animal body is the fact that each organ has more substance than is necessary to do its normal amount of work. Teleologically it is easy to see that some such arrangement is necessary for successful survival, but it is more difficult to imagine the mechanism by which it is kept in working order. If a muscle is used less it grows smaller, and if it is used more it grows larger. In each case it preserves the margin of power which is known as "reserve force," despite the definite general relation between quantity of substance and quantity of function. In a recent number of the *Journal of Pathology and Bacteriology* (vol. xxv. p. 414) Dr. V. R. Khanolkar makes some interesting speculations and observations which seem to throw light on the problem, and he extends them into suggestions which may clear up some obscure points in respect of the distribution of pathological lesions in organs. So long ago as 1871 Bowditch formulated the proposition that if the frog's heart responds at all to an artificial stimulus it responds with the greatest contraction of which the muscle is at the time capable. This principle of "all or nothing" has since been extended to other excitable tissues, most convincingly to muscle and nerve, and by implication to glands which receive their normal stimuli through the nervous system. On this basis, moderate activity of a skeletal muscle means maximal activity of a moderate number of the units, in this case muscle fibres, of which it is made up and not moderate activity of all the units.

In other words, in ordinary circumstances only a proportion of the units of any organ are active at any one time. How then do the other units escape the consequences of the rule that tissue which is not used atrophies and disappears? Marey in 1885 found that the responsivity of the frog's heart to external stimuli is least when it is actually contracting and is only gradually restored to normal after the contraction is over. Each period of activity is thus followed by a "refractory period" in which the tissue will not respond to a strength of stimulus which would normally rouse it to activity, the resistance to excitation fading away until the normal excitability is regained. This refractory phase has been closely studied in nerve muscle and sense organs, and Gotch described it as a general phenomenon of living substance. In this way a rotation of activity among the units of any organ is brought about: with moderate activity in response to moderate stimulation a proportion of the units are constantly in action, but as the refractory period of each one comes on it stops working and its function is taken on by another unit with its activity more remote and its refractory period completed. As the activity of the whole organ is increased owing to stronger stimulation, the refractoriness of units is broken through first in those the activity of which is remote, next in those which have functioned more recently. Finally, with maximal stimulation all the units are forced into simultaneous action.

It seems likely that these principles, elucidated by the classical method of "wiring frogs on to machinery," are applicable to other tissues in which their demonstration is more difficult. What constitute anatomical "units" is not known. In nerve and muscle they are the individual fibres, in the central nervous system probably nerve cells, in the kidney possibly the glomerular-tubal systems, in glands apparently groups of adjacent cells—but they might be parts of organs, cells, or even parts of cells. Dr. Khanolkar has specially concerned himself with the kidney, and supposing that each glomerulus with its efferent tubule is a unit, points out that the hypothesis would explain the irregular distribution of the lesions in the common chronic degeneration of that organ. Assuming that the original injury is due to some poison circulating in the blood, it follows that more of it will reach active than passive units since activity is always associated with a local increase in blood supply. On general grounds also it is quite likely that functioning cells are more reactive and hence more easily poisoned than cells at rest. In chronic general nephritis some glomeruli are destroyed while others appear to escape injury altogether, and the diseased and healthy units are found scattered uniformly all over the organ. It is suggested that the injured units are those which happened to be active when a toxic concentration of the poison was in the blood. Extending the idea to other organs, it follows that activity always renders a tissue more susceptible to poisonous substances, which may be the explanation of why the parts of the nervous system most constantly in heavy use are specially liable to suffer in general lead poisoning and other similar relations. Failure of an organ from over use might in part be due to this, in part to the absence of rest for any of the units. It is well recognised that hypertrophy of skeletal muscle is best secured by exercises which seem absurdly mild: on the hypothesis of unit activity it is easy to understand why light dumb-bells should keep more units in the best possible condition than heavy ones.

Dr. Khanolkar adduces experimental evidence that in the kidney during moderate activity only some of the glomeruli are in action, while more or all will excrete actively when the organ is strongly stimulated with diuretics. Incidental observations on the adrenal medulla, pituitary, pancreas, and salivary glands give histological evidence of the same partial activity. The whole fits in well with Krogh's recent demonstration that many capillaries in normal organs are at any one moment closed and out of action.

Climates of the Past.

W. R. ECKARDT, of Essen, has contributed a memoir, "Paläoklimatologie, ihre Methoden und ihre Andwendung auf die Paläobiologie," to Prof. Abderhalden's comprehensive "Handbuch der biologischen Arbeitsmethoden" (Urban und Schwarzenberg, Berlin), of which it forms Heft 3 of Abteilung 10. It is written in what may be called the *über Alles* type of German, without much consideration for the southerner or the stranger, and sentences containing more than 100 words are not uncommon. It embodies, however, a valuable and critical review of the way in which various classes of geological evidence may be used as indications of the climatic environment of the faunas and floras of the past.

The character and colour of fossil soils are discussed by Dr. Eckardt, equally with the distribution of

fossil organisms. It is pointed out that areas of bogland (*Sumpfflachmoor*) and peat may arise even in tropical conditions, moisture and low-lying land being the real necessities, and Wegener is cited as regarding all the great coal-basins as formed in a zone of equatorial rains. The important question of annual rings in wood, discussed recently in Deecke's "Paläophytologie" (see NATURE, September 16, p. 375), receives careful consideration, and the author concludes that these rings cannot be used by themselves as elucidating climatic conditions. Dr. Eckardt supports the view that seasonal changes of temperature have been felt in polar regions even when the climate was warmer over the whole earth; but at certain periods mild subpolar winters have been associated with summers much hotter than those of the present day.

A. Handlirsch is interestingly quoted as showing how the length of the anterior wing in insects may be used as an indication of prevalent temperature, since it increases at the present day from an average of 7 mm. in central Europe to 16 mm. in the tropics. The length in Lower and Middle Carboniferous strata in our latitudes is as much as 51 mm., but decreases in Upper Carboniferous and Permian times to 20 or to 17 mm. Little that bears on his subject has escaped Dr. Eckardt, and the correlation of scattered scientific observations, in the hope of solving problems, is aptly illustrated in his concluding sentence, where he quotes Eckholm as showing that great importance must be attached to the obliquity of the ecliptic in explaining the post-Glacial distribution of the hazel-nut in Scandinavia.

Dr. Eckardt points out that at the present day the relative distribution of land and water has an influence on climate only about a third or a quarter as important as that of latitude. Prof. E. W. Berry, however, in a paper on a possible explanation of Upper Eocene climates (Proc. Amer. Phil. Soc., vol. 61, p. 1, 1922), urges that a prevalence of low-lying land as against mountain areas, and an enlargement of oceanic areas, allowing of free circulation from broad equatorial basins to the poles, was a sufficing cause of the warmer, though still zonal, conditions revealed by Eocene vegetable remains. The Upper Eocene hazel, for example, came no farther south in Eocene times than lat. 45°, because the Atlantic basin resembled in breadth that of the present Pacific Ocean. The author even looks back to the views of Lyell, and suggests that "the distribution and altitude of the land and sea" may have accounted for the glacial epochs.

A. Brockmann-Jerosch, who is much quoted by Dr. Eckardt, has recently suggested that glacial conditions in Switzerland were favoured by an oceanic climate and a copious rainfall ("Die Vegetation des Diluviums in der Schweiz," Conférences de la Soc. Helvétique des Sci. nat., 1920, p. 73). Perhaps the proximity of the mountains in this area removed one of the factors relied on by Berry. There is clearly much philosophical discussion still before us in palæoclimatology. G. A. J. C.

Studies on Phytophthoras.

IN the *Mededeelingen v. d. Landbouwhoogeschool*, Wageningen, xxiv., No. 4, 1922, Miss de Bruyn publishes (in English with a Dutch summary) a paper entitled "The saprophytic life of Phytophthora in the soil." After reviewing the literature pertaining to fourteen species of the genus in relation to the question of their capacity for life as saprophytes in the soil, Miss de Bruyn describes her own work on the cultivation of the three species, *P. Syringæ*, *P. erythroseptica* and *P. infestans*, in soils of different types. Most of the experiments were carried out with soil which had previously been sterilised, and details of the growth in this medium are given in each case.

The general conclusion reached is that Phytophthoras are not such obligate parasites as was formerly supposed, and it is claimed that the experiments carried out prove that each of the species mentioned can actually live and grow in the soil. Cultures on sterilised soil as well as on other media were exposed out of doors to rather severe frost for several days, and it was found that *P. Syringæ* and *P. erythroseptica* survived such treatment. So far as the cultures in soil are concerned, however, it would appear that such survival may have been due to the presence of oospores. In the case of *P. infestans* (the oospores of which are still unknown in Nature) the results of exposure to similar conditions were not concordant, and the question as to whether this species can overwinter in the soil is regarded as unsolved. It was found, however, that when growing on sterile raw potato slices, *P. infestans* survived a temperature of −9° C., although at this low temperature the potato slices themselves were blackened.

Attempts were made to cultivate *P. Syringæ* and *P. erythroseptica* in non-sterilised soil, but the results do not appear to have been very satisfactory. It seems clear that further and more critical work will have to be carried out before it can be accepted as convincingly established that these two fungi are really capable of sustained growth and development in ordinary soil. No information is given as to whether *P. infestans* was found to live and grow in ordinary unsterilised soil; and speculation as to whether the survival of this fungus in the soil from season to season may account for primary outbreaks of potato blight seems therefore altogether premature.

Another recent contribution to our knowledge of this fungus is contained in a doctorate thesis presented to the University of Utrecht by Miss M. P. Löhnis, entitled "Onderzoek over *Phytophthora infestans* (Mont.) de By. op de aardappelplant." (Wageningen, H. Veenman, 1922.) An account of pure culture work with various media is given; immature oogonia and oospores were found twice in cultures on raw potato and Quaker Oat agar.

Experiments on the manner in which infection of the potato occurs are described, and in discussing the question of the propagation of the blight from season to season it is recorded that on five occasions a diseased tuber was found before any infection of the foliage was apparent. It is suggested that the fungus may perhaps subsist in the soil, but this point is not yet regarded as definitely established. Other matters dealt with are the influence of the stage of development of the plant on its susceptibility to infection, the mode of entry into the tubers and growth of the fungus in the subterranean parts of the plant, the formation of wound cork and varietal resistance to blight. The thesis is provided with a summary in English, and a more detailed abstract of it will be found in the *Review of Applied Mycology*, I. 8. Aug. 1922, p. 253.

Aeronautical Research Committee.

THE report of the Aeronautical Research Committee for the year 1921–22 (H.M. Stationery Office, 1922, 2s. 6d.) consists of two parts. The first—the report proper—gives a formal résumé of the activities of the committee, and of its sub-committees on air-inventions, aerodynamics, engines, materials and chemistry, meteorology, accidents, fire prevention, and load factors. A feature of great interest in this report is the reference to the loss of the Airship R38 and of the valuable lives thus cut short. The committee deprecates the tendency to make development in aircraft depend upon the investigation of accidents, and advocates strongly the method of systematic research directed to each element of the design. It asserts the necessity of employing the highly trained and skilled researchers that are now available for the scientific study of aeroplane and airship development, and on the question of finance counters the "axe" enthusiasts as follows: "The money which would have come to this country had R38 been a success would have maintained the research of the Committee in full activity for a period of five years. In another way it may be stated that, should the work of the Committee lead to a reduction by one of the aeroplanes written off per year as a result of crashes, it would have earned the cost to the Air Ministry of the fees paid to its members." This is a sufficiently cutting condemnation of so-called "economy," but one wonders how much effect it will produce in official circles.

The second part of the report consists of a supplement, giving in some detail an account of the researches that have been and are being conducted, with indications of their scope and results. In aerodynamics the chief topics studied have been control at low speeds, the general theory of aeroplane flight (investigated by Prof. G. H. Bryan), aerofoils, the circulation and vortex theory of Prandtl, etc. On internal-combustion engines work was done on trustworthiness, sparking-plugs, fuels, etc., while it is of interest to read that a beginning is being made (at Cambridge University and at Armstrong College, Newcastle) to bring University workers into contact with Government aircraft research. The meteorological work dealt with the structure of the atmosphere and the formation of cyclones and fog, and with instruments, etc.

The part of the supplements dealing with accidents will naturally attract much notice. The accident to the Tarrant Triplane "Tabor" led to the discovery of inadequacy in the rudder control, and to the development of relay controls for dealing with the longitudinal control plane. Airship R36 suffered accidents which showed the necessity for experimental work on an actual airship. In the case of the R38 the disaster was due to structural weakness in the design. No calculations had been made of the stresses caused by aerodynamical forces and movements, although such stresses may exceed considerably those due to weight and buoyancy. While it appears that model data would, indeed, have been sufficient to indicate the kinds of stresses that would be obtained in flight manœuvres, the committee emphasises the importance of full-scale work.

It is not possible here to mention all the numerous items of aeronautical research referred to in the report. Suffice it to add that, at a ridiculously small cost to the nation, work is being done that will add as much to our national security and commercial prosperity as the many millions we spend so thoughtlessly in response to popular clamour.

The Hydrautomat.

THE problem of raising a small quantity of water to a considerable height by utilising the energy of a larger mass of water has been solved in a number of ways. In the seventeenth century, the City of London was supplied with water pumped from the Thames by means of a reciprocating pump, driven by a crank which was made to rotate by a water-wheel turned by the flow of the river. The "hydraulic ram" is a device that has been successfully used, and recently there has been developed a device, the hydrautomat, which utilises the pressure of the atmosphere to lift water (Allen Hydrostatic Pump Syndicate, Ltd., 110 Victoria Street, S.W.1).

Let it be supposed that there is a source of supply at a height of H feet above a tail race. For example, water might be led along a channel constructed by the side of a falling stream, the slope of the channel being less than that of the stream, to some point at which there is a difference of level H feet between the water surface in the channel and the river. At a height H/2 from the river bed is constructed a closed tank which is connected to the supply channel by means of a siphon pipe entering the closed tank at the bottom, and to the bottom of the tank is connected another siphon which has a rising limb and a discharging limb taken down to the river bed. To the top of the closed tank is connected an air-pipe which has connexions to a series of closed tanks placed at various heights, on a hillside, say. Each of these closed tanks has a siphon pipe led from the bottom of the closed tank to the top of an open tank at a higher level. From the top tank of all the water can be taken to any desired point.

Let now the water be allowed to flow from the channel into the lowest closed tank, entering at the bottom. The air in this tank will be compressed and will be conveyed under pressure along the rising pipe, and to each of the closed tanks above, from which the water is raised to the open tanks above. When the pressure in the lowest tank reaches a certain value, the discharging siphon automatically operates. The escaping water acts upon a flat vane, which is connected to a lever controlling a valve which cuts off the supply from the channel to the lowest tank, and a partial vacuum is produced in the closed tanks. Water is thus drawn from any one of the open tanks to the closed tank immediately above it. There is thus an alternate delivery and suction stroke for each lift of ½H. The only valve is that between the channel and the lowest tank. The device is an exceedingly interesting and simple one, and the plant required is inexpensive in first cost and upkeep. A plant is working at Carshalton, Surrey.

University and Educational Intelligence.

BRISTOL.—A tablet bearing the names of all members of the University who fell in the war is shortly to be placed in the new University buildings. The war memorial committee is very anxious to guard against omissions, and will be grateful if relatives of the fallen who have not already communicated particulars will inform the secretary of the committee accordingly.

CAMBRIDGE.—The offer of the Ministry of Agriculture to found a professorship of animal pathology with funds from the Development Commissioners has been accepted. The Council of the Senate has published recommendations as to the duties and emoluments of the professorship, and if these are approved the election to the new chair need not be long delayed.

LEEDS.—At a meeting of the Council on February 21, Prof. Smithells was reappointed to the office of Pro-Vice-Chancellor.

Mr. James Robb has been appointed district lecturer in agriculture.

It has been decided to reinstitute a formerly existing professorship of therapeutics in the department of medicine, and to elect Dr. W. H. Maxwell Telling to this chair.

LONDON.—The Senate has made a grant of 75*l.* from the Publication Fund to the Rev. F. J. Wyeth in aid of the publication by the Royal Society of his D.Sc. thesis entitled "The Development of the Auditory Apparatus and Associated Structures in *Sphenodon Punctatus*."

The Senate has adopted a resolution recording with great regret the resignation of Dr. M. J. M. Hill of the Astor chair of pure mathematics at University College, which he has occupied since 1884.

The Academic Council has prepared a table showing the universities from which, up to the present, applications have been received for registration as Internal Students for the Ph.D. degree. The classified totals are as follows :—

Great Britain (London 171) and Ireland	255
Europe	10
Australia and New Zealand	16
United States of America	30
India	62
South Africa	3
Canada	8
Japan	1
	385

The degree of D.Sc. (*Engineering*) has been conferred upon Mr. A. E. Clayton for a thesis entitled "Papers on Alternating Current Machinery" and other papers.

The council of Bedford College for Women invites applications from women for a post-graduate scholarship in sociology, value 150*l.*, for one year. Further information is obtainable from the Secretary of the College, Regent's Park, N.W.1.

MANCHESTER.—The Council has approved a scheme for the establishment of a Colloids Research Laboratory in the University. A sum of 11,842*l.* has been subscribed and given to the University towards the endowment and cost of the equipment of the department. Mr. D. C. Henry, at present a lecturer in chemistry, has been appointed lecturer in colloid physics and will take charge of the Laboratory, which will be known as "The Graham Research Laboratory." The Council has expressed its hearty appreciation of the gift to the various subscribers, and especially to Dr. Kenneth Lee, who has been largely responsible for the scheme.

Mr. Norman B. Maurice has been recommended for the degree of Ph.D., his thesis being "On the Unsaponifiable Constituents of Commercial Rosins."

OXFORD.—The Edward Chapman Research prize of Magdalen College is to be offered for competition at the beginning of the summer term this year for a published piece of original research in one of the following departments of natural science: physics or chemistry, including astronomy, meteorology, mineralogy, geology, or the biological sciences of zoology and botany, whether treated from the morphological, palæontological, physiological, or pathological point of view. The prize is of the value of 20*l.* and restricted to members of Magdalen. Further particulars are obtainable from Mr. R. T. Gunther, Magdalen College. Competing essays must reach him not later than May 1.

THREE fellowships, tenable for two years, each of the annual value of 200*l.*, are being offered by the University of Wales to graduates of that university. Applications must be received before June 1 next by the Registrar, University Registry, Cathays Park, Cardiff, from whom further information may be obtained.

NOTICE is given that the tenth election to Beit fellowships for scientific research will take place on or before July 16 next, and that the latest date for the receipt of applications is April 19. Forms of application and all information may be obtained from the Rector, Imperial College, South Kensington, S.W.7, upon written request.

A LECTURE on the work and aims of the newly-established West Indian Agricultural College, Trinidad, will be given at Vernon House, Park Place, St. James Street, S.W., at 8 P.M., on Monday, March 5, by Mr. W. R. Dunlop, of the Imperial Department of Agriculture, who has taken an active part in the organisation of the College. The chairman at the lecture will be Dr. A. W. Hill, director of the Royal Botanic Gardens, Kew.

THE next meeting of the Imperial Education Conference is to be held in London at the end of June of this year. The last meeting was held in London in 1911, and but for the war the Conference would have met in 1915. The Conference will be attended by official representatives from the Education Departments of the Self-governing Dominions and Colonies and the British Isles, and various matters of common interest will be discussed, including the question of the interchange of teachers within the Empire.

THE third report of the British Association Committee on Training in Citizenship, presented at the Hull meeting in September last, has recently been issued and is obtainable from the secretary of the committee, Lady Shaw, 10 Moreton Gardens, S.W.5. The greater part of the report is devoted to an appendix containing a bibliography of books on civics. About 12 pages are occupied by this list, which mentions altogether about 400 books, pamphlets, and magazine articles. It was found impossible and undesirable to include all books bearing on the subject; there can be no doubt, however, that any serious student with this list in hand could rapidly make himself familiar with the various aspects of civics and the different points of view apparent in the treatment of the subject. As is natural, only publications of the last few years are, in general, mentioned. One suggestion, of special interest to readers of NATURE perhaps, occurs after a study of the report: What would an anthropologist say to this vast literature of citizenship? He would, we judge, divide it into two classes: first, those writings in which citizenship is looked at as the natural course of life in a human community, and in relation to the essentially simple occupations on which all human life is based; and, second, those in which chief place is given to current, and often unscientific, views of human life and organisation. The choice between those two types of book would be of importance not only in connexion with citizenship, but also in connexion with science-teaching.

THE jubilee of the University Extension movement will be celebrated this year at Cambridge, where it began under the leadership of Prof. James Stuart, of

Trinity College, in 1873. Delegates from all the universities of the Empire and many of those of the United States, as well as representatives of local lecture centres and tutorial classes and local education authorities, will be invited to attend a conference, to be opened on July 6 by Lord Balfour as Chancellor of the University, which will last until July 10. The annual summer meeting will be held at Oxford on July 27, when Sir Michael Sadler will deliver the inaugural lecture of a course on "Universities and their Place in National Life." The list of lecturers will include Prof. Clement Webb, Dr. Selbie, Canon Ollard, Principal Ernest Barker, Dr. Cranage, Dr. L. P. Jacks, Mr. Ramsay Muir, Sir Gregory Foster, Principal Childs, Mr. J. A. R. Marriott, Mr. Albert Mansbridge, Mr. J. R. M. Butler, and Miss Maude Royden, and probably Dean Rashdall, Prof. Rait, and Mr. Coulton. The subsidiary subject of study at the meeting will be "The Social and Economic Problems of English Country Life," introduced by Sir Daniel Hall. The following statistics are taken from annual reports for 1921–22 on University Extension work of the Universities of Oxford, Cambridge, and London, the figures for the several universities being given in the above order: number of courses, 121, 92, 144; enrolment, 12,000, 11,721, 12,431. Summer vacation courses are being organised this year by or in connexion with almost all the English universities, the University of Wales, and the University of Aberdeen. Holiday courses for foreigners will be provided at Cambridge and London.

THE results of a comprehensive investigation of the home-residence of university students in 1920–21, undertaken by the United States Bureau of Education, have been tabulated in Bulletin, 1922, No. 18. On an average, one-fourth of the students in the universities and colleges of a State came from outside the State and 1½ per cent. came from foreign countries. Of these 6900 foreigners, Asia contributed 2506, North America 2156, Europe 1379, South America 563, Africa 223, Australia 61, China 1443, Canada 1294, Japan 525, West Indies 396, Russia 291, Mexico 282, India 235, Central America 184, France 160, Great Britain 149, South Africa 141, Brazil 126, Norway 94. From United States possessions (chiefly the Philippines, Hawaii, and Porto Rico) there were 1456 students. The returns published by the University Grants Committee for the same year show that of full-time students in universities and university colleges in Great Britain in receipt of treasury grant (but excluding Oxford, Cambridge, Guy's Hospital Medical School, and Trinity College, Dublin), 42 per cent. came from places beyond 30 miles from the institution, 6·2 per cent. from beyond the United Kingdom, and 1·7 per cent. from foreign countries. Turning to the Universities Yearbook, 1922, we find the percentage of students from outside the United Kingdom was 8, the difference being due to including returns from Oxford, Cambridge, Dublin, and Guy's: Asia contributed 1576, America 781, Europe 645, Africa 1187, the Pacific 281, China 143, Canada 200, Japan 73, West Indies 101, Russia 91, India 1240, France 62, U.S.A. 400, South Africa 832. Similar statistics in the Swiss *Bulletin Universitaire* of November last show that of students attending the seven Swiss universities in 1922, 20 per cent. were foreigners, the proportion being highest in Fribourg, Geneva, and Lausanne; at the Federal Polytechnic, Zurich, the proportion was 16.

IN view of the recent recommendation of the Board of Education's Consultative Committee that more attention should be paid in secondary schools to the cultivation of music and that this subject should be given full recognition in the first and second school certificate examinations, the report recently published by the United States Bureau of Education (Bulletin, 1921, No. 9) on the "Present Status of Music Instruction in Colleges and High Schools" is of interest to teachers and others in this country. It appears that nearly half of the universities and colleges in America allow entrance credit in musical theory and more than one-third in "appreciation," including history, form, and so on. Recognition of applied music for entrance qualification is a matter of very recent development, but already in 1919 more than one-sixth of these institutions allowed entrance credit in piano, violin, etc., and half as many recognised performances in orchestra, glee-clubs, and chorus singing. In 25 per cent. credit for applied music is allowed toward the B.A. or B.Sc. degree. In general it may be said that there is ample evidence of increasing interest in the development of music as a social, cultural, and professional subject in the universities and colleges. The same may be said of the high schools, where orchestra is becoming an increasingly important feature of school life and courses in harmony and appreciation are often provided. The report does not distinguish between boys and girls except as regards glee-singing, of which there appear to be almost as many boys' as girls' courses. The fact that credit toward school leaving certificates is granted in a large proportion of the schools offering music courses seems to indicate that there is an effort to present these courses in a manner sufficiently thorough to make them compare in requirement with the other courses of the high school.

AN American criticism of higher education in Australia and New Zealand has been published by the United States Bureau of Education in Bulletin, 1922, No. 25. It is based on a visit to Australasia in 1920 by Dr. C. F. Thwing, president emeritus of Western Reserve University and author of "Universities of the World" (Macmillan, N.Y., 1911). Among other differences between American and Australian universities Dr. Thwing notes that whereas one half or more of American undergraduates look forward to a business career, most of those in Australia are preparing for the professions and only a very few go into business: most of the engineering graduates enter the Federal Public Works departments. Training for the professions, while thorough in a practical sense, lacks generally the liberal foundation given in the American college. Dr. Thwing, who is interested chiefly in the sociological aspects of university questions, considers that notwithstanding the apparent success of the adult-education movement in the universities, their influence on the community is slight and there is a tendency for their members to confine themselves to their special work and avoid all public responsibility. He believes that in the presentation of many subjects, such as government and economics, teachers are liable to be hampered by the fact that the university depends for grants for its support on a government which is often controlled by doctrinaire leaders of the so-called working classes. Until recent years no chair of economics was established in any university, although education for citizenship should have been one of the principal services of the university to a community in which there is a dearth of men of any great distinction in the political sphere, and parties are generally content with negative cries. While Dr. Thwing was gathering materials for his account of Australasian universities, Prof. E. R. Holme, of Sydney, happened to be similarly engaged in studying higher education in America and preparing his book on "The American University."

Societies and Academies.

LONDON.

Royal Society, February 22.—G. I. **Taylor** and C. F. **Elam**: The distortion of an aluminium crystal during a tensile test (Bakerian lecture). A rectangular specimen 1×1×20 cm. cut from a round bar of aluminium, which had been treated by the method of Carpenter and Elam, so that it consisted of one single crystal, was stretched through successive extensions of 0, 10, 20, 30, 40, 60, and 78 per cent. of the original length. At each stage of the test, distortion was determined by measurements of scratches ruled on the surface and the directions of the crystal axes were determined by X-ray analysis. The method for determining the nature of the distortion was to find lines of particles which were unextended by the strain. The directions of these lines lie on a quadric cone, which evidently has two positions corresponding with the two configurations from which it was derived. It was found that, up to 40 per cent. elongation, the "unextended cone" was of a degenerate form consisting of two planes, one of which contained in all cases the same particles, while the other contained different particles for different strains. Distortion was due to slipping or shearing over the former plane. By X-ray measurements it was found that the slip plane was identical with an octahedral (III) plane of the crystal. The direction of the shear was along one of the three principal lines of atoms in the octahedral plane. When the specimen was extended beyond 40 per cent. elongation, the effect of the shear was to rotate the axis of the specimen relative to the crystal axes in such a way that another (III) plane came into a position where its inclination to the axis was the same as that of the slip plane. In these circumstances slipping might occur on both planes simultaneously.

Aristotelian Society, February 5.—Prof. A. N. Whitehead, president, in the chair.—May **Sinclair**: Primary and secondary consciousness. Consciousness is defined as a state of awareness, of knowing that there is something "there." Idealism regards the world as arising in consciousness; realism regards it as existing apart from and independent of consciousness. Primary consciousness is all that is present to the subject in perception, contemplation, memory, and immediate thinking, before reflection, judgment, and reasoning has set in. It says nothing about the external and independent existence of its content or object. Secondary consciousness is consciousness of consciousness. It is all reflection, judgment, reasoning, all the play of mind round and about its object. Secondary consciousness is always distinguishable from its object and primary consciousness is not. Therefore secondary consciousness alone supports the realist's assumption and provides the basis for his attack. At the point where consciousness is most vivid, most intense, its identity with its object is absolute: as in the consciousness of a lightning flash, of shell-fire, or toothache. Here there is no possibility of analysing into consciousness and independent object. Yet at this point primary consciousness is the intensest affirmation of its object's existence. There is no reason why this should be so if realism were true. We cannot then distinguish between consciousness and its object. When we seem to be doing this we are really distinguishing between primary and secondary consciousness, and the distinction falls within consciousness. Implicit judgments of perception present a difficulty. They would seem to be primary. But all explicit judgments are clearly secondary. The realist judgment is of this nature and it comes too late to save the independent reality of the object.

Royal Anthropological Institute, February 6.—Mr. H. J. E. Peake in the chair.—E. O. **Rutter**: The natives of British North Borneo. Fifty years ago the native population of North Borneo consisted of pirates, who ranged along the coasts, and of head-hunters, who lived in small communities in the hills. The natives may be divided into three groups—the people of the coast, the people of the plains, and the people of the hills. The coast natives are mainly Bajaus, Sulus, and Illanuns; they are Mohammedans and, for the most part, sea-gipsies. Boats take the place of caravans and they make their living from the produce of the sea. Even when they build houses they are usually constructed over the water upon the seashore or the river banks. Some are accomplished horsemen. The inhabitants of the plains are the Dusuns, a race of farmers, law-abiding and industrious, who cultivate the rice which is their staple food. Some of the Dusuns come into the hill group and with them are the Muruts. The latter are the most primitive race. They live in villages of one or perhaps two houses 200 or 300 feet in length, perched high upon a hill to be out of the way of raiding-parties. Only within the last few years have they abandoned head-hunting, which was the outcome of feuds between villages. Peace terms were sealed by bathing in the blood of buffaloes and planting stones as witnesses of oaths of peace.

Linnean Society, February 15.—Dr. A. Smith Woodward, president, in the chair.—A. M. **Alston**: On the method of oviposition and the egg of the beetle *Lyctus brunneus* Steph.—V. S. **Summerhayes**: Lichens collected by the Oxford University Expedition to Spitsbergen in 1921. In all, 68 species in 27 genera of lichers were found, chiefly on Bear Island, a mass of limestone rock, and Prince Charles's Foreland, of siliceous rock.—F. Howard **Lancum**: Curious oviposition by a specimen of the clouded yellow butterfly, *Colias edusa*. A female *Colias edusa* refused to deposit ova and declined to feed. At the end of a fortnight it was transferred casually to a leaf of a potted plant of white clover, and it laid one egg, and by moving it seventeen times in succession to different leaves, seventeen eggs were obtained. It was curious that it would not deposit an egg until it was moved.—B. Daydon **Jackson**: C. A. Agardh's "Aphorismi botanici," Lundæ, 1817–26, 8°. The volume confirms the practice prevalent in Scandinavia to the middle of the previous century, the Præses being the actual author, and the Respondentes being little better than dummies.

Royal Meteorological Society, February 21.—Dr. C. Chree, president, in the chair.—E. **Gold**: A proposed reform of the calendar by Dr. C. F. Marvin, Chief of the U.S. Weather Bureau. Dr. Marvin in his pamphlet states that the only modification of the Gregorian calendar which meets the need of the meteorologist is one which calendars the year in exactly 13 months of 28 days each, each of which would start on a Sunday. One day in each year and an additional day in leap year, should be set apart as public holidays.—S. **Fujiwhara**: (1) On the growth and decay of vortical systems. Water vortices of a like sense of rotation attract, and vortices of opposite sense repel each other. Vortices grow by amalgamation, and cyclones and anticyclones can be regarded as following similar laws. The

equation of growth of energy of vortices is similar to the equation for vital growth given by Brailsford Robertson. (2) On the mechanism of extratropical cyclones. From the equation for change with time of the vorticity of horizontal motion in the earth's atmosphere devised by Hesselberg and Friedmann, the most important source of energy of a cyclone is in the vorticity of the surrounding field. The feeding of a cyclone along the steering surface (of the Polar Front theory) is capable of explanation as the absorption by the main whirl of the horizontal whirl which forms at the surface.

EDINBURGH.

Royal Society, February 5.—Prof. F. O. Bower, president, in the chair.—A. G. **Ogilvie**: Physiography of the Moray Firth coast. The coastal features along the Moray Firth from Golspie to Inverness, thence east to Port Gordon, were described. The Firth seems to occupy the site of a foundered crustal block, bounded by known fractures on the north-west, and by possible faults on the south side. Four marine platforms occur there, but the detailed levelling shows that the inland margin of the highest beach is never above ninety feet. Some of the flat expanses of gravel and sand, hitherto regarded as remnants of this terrace, seem to be outwash aprons from the retreating glaciers. Special attention was directed to the constructive action of the sea in originating shingle bars and sand bars, which unite to form forelands and strand plains.

CAMBRIDGE.

Philosophical Society, February 5.—Mr. C. T. Heycock, president, in the chair.—E. A. **Milne**: The escape of molecules from an atmosphere, with special reference to the boundary of a gaseous star.—J. E. **Jones**: Free paths in a non-uniform rarefied gas with an application to the escape of molecules from an isothermal atmosphere. In a gas such as exists at the outer fringes of an atmosphere the usual formulæ of the kinetic theory for the calculation of free paths are no longer applicable. The necessary generalisations have been applied to find the condition under which a molecule may escape from an atmosphere. The total number of molecules lost in this way has then been enumerated by a more detailed method than has been used hitherto.—J. S. **Rogers**: L series of tungsten and platinum.—R. H. **Fowler**: Contributions to the theory of α-particle phenomena. Pt. I. Stopping powers. Pt. II. Ionisation.—C. G. F. **James**: The representation of varieties in space of three and four dimensions.—M. J. M. **Hill**: On the fifth book of Euclid's elements.—G. H. **Hardy**: A chapter from the notebook of Mr. Ramanujan.—E. C. **Titchmarsh**: Hankel transforms.—J. P. **Gabbatt**: A generalisation of Feuerbach's theorem.

PARIS.

Academy of Sciences, February 5.—M. Albin Haller in the chair.—G. **Bigourdan**: The "Cabinet du Roi" and the forgotten discoveries of Rochon. An historical account of the installation of this observatory in 1761, its equipment and an account of the astronomical work done there by Noël, Leroy, and Rochon.—Charles **Richet**, L. **Garrelon**, and D. **Santenoise**: The laryngo-cardiac reflex.—A. **Blondel**: Influence of the speed governors controlling turbo-alternators on the oscillations of the electrically connected sets. Case of indirect regulation.—R. de **Forcrand**: The hydrates of krypton and argon. The dissociation pressures of these hydrates have been measured at varying temperatures and the heats of formation calculated from the results.—J. **Roudaire-Miégeville**: The grapho-mechanical determinations of systems of real or imaginary solutions of algebraical equations. A development of the work of Kempe and of Koenigs on tracing algebraic curves by an articulated system.—Charles **Fremont**: The cause of the formation of the elongation at constant load near the elastic limit in testing mild steels.—Th. **Moreux**: The probable cause of the anti-solar glow.—A. **Buhl**: The mass and electromagnetic fields of Th. De Donder.—Paul **Dienes**: Tensorial geometry.—J. **Haag**: The distribution of the molecules of a gaseous mass; application to the formula of Van der Waals.—Albert **Pérard**: Study of some neon radiations with the view of their applications to metrology. A comparison of the cadmium line (508·582 mμ) with five neon lines. The ratios of the cadmium and neon lines are not constant. The systematic variation proved that the neon lines were very close doubles.—L. **Bouchet**: Application of the plane-cylinder electrometer to the determination of the inductive capacities of solid substances.—R. **de Mallemann**: Determination of the electromagnetic double refraction of active liquids.—René **Ledrus**: The increase of dispersion in photo-electric X-ray spectra.—St. **Procopiu**: The arc spectra of metals in various media and in a vacuum. The metals studied were copper, gold, zinc, cadmium, magnesium, calcium, and aluminium, and the arcs were produced in air, hydrogen, coal gas, nitrogen, water, and in a vacuum. All the metals gave a stable arc in nitrogen, including magnesium, calcium, and aluminium, with which it is difficult to maintain an arc in air. Stable arcs were also produced in a vacuum. Details are given of the change produced in the lines.—P. **Dejean**: Correlation between the hypothesis of the elementary demagnetising field and the theory of the molecular field.—E. **Darmois** and J. **Périn**: Dextro malic acid and the utilisation of ammonium molybdomalate for the resolution of racemic malic acid. The dextrorotatory malic acid prepared by Walden's method is partially racemised, and it contains about ¾ dextrorotatory acid and ¼ lævorotatory acid. By conversion into ammonium dimolybdomalate a separation can be effected.—G. **Claude**: The application of coke oven gas to the synthesis of ammonia. After removal of benzol by oil and carbon dioxide by lime water, the remaining gases are separated by fractional condensation, the hydrogen passing on to the ammonia apparatus.—Raymond **Delaby**: The characterisation of the alkylglycerols.—Léon **Bertrand** and Antonin **Lanquine**: Extension of the *duplicatures provençales* under the Cheiron layer (Alpes-Maritimes) to the west of the Var valley.—Filippo **Eredia**: The dryness of Italy during the year 1921.—E. and G. **Nicolas**: The influence of hexamethylene-tetramine and formaldehyde on the internal morphology and chemical changes in the bean.—A. **Polack**: The physiological determinism of the accommodative reflex of the eye.—J. **Dragoiu**, F. **Vlès**, and M. **Rose**: Cytological consequences of the lowering of the hydrogen ion concentration on the evolution of the egg of the sea-urchin.—A. **Goris** and P. **Costy**: The urease of fungi. The urease from *Boletus edulis* was studied: detailed accounts of the effects on the enzyme of heat, acids, alkalies, neutral salts, and antiseptics are given.—L. G. **Seurat**: The fauna of penetration of South Tunisian rivers.—R. **Herpin**: The sexual relations in *Perinereis cultrifera*.—L. **Léger** and E. **Hesse**: A fungus of the Ichthyophonus type, a parasite of the intestine of the trout.

SYDNEY.

Royal Society of New South Wales, December 6.—Mr. C. A. Sussmilch, president, in the chair.—Miss Ida **Brown**: Notes on hornblende and bytownite from hypersthene gabbro, Black Bluff, near Broken Hill. A description of the separation of hornblende and plagioclase felspar from a gabbro which occurs about six miles to the south-east of Broken Hill, and a discussion of their chemical composition and optical properties.—H. G. **Smith** and J. **Read**: The glucoside occurring in the timber of the red ash, *Alphitonia excelsa*, Reiss. The red colour of this timber is due to the oxidation, upon exposure to light and air, of a characteristic constituent, which shows a marked resemblance to fustin, the glucoside of young fustic, *Rhus cotinus*. The substance sometimes occurs as a chalky deposit in the cracks and shakes of the timber, and it may also be extracted from the wood shavings with boiling water. It melts at 218-219°, and is probably identical with the glucoside of *Rhodosphacra rhodanthema*, having the formula $C_{36}H_{30}O_{16}$. It forms a mono-potassium salt, and a corresponding ammonium salt. It is hydrolysed with extreme difficulty by boiling dilute acids.—A. R. **Penfold** and R. **Grant**: The economic utilisation of the residues from the steam rectification of the essential oil of *Eucalyptus cneorifolia* and the germicidal values of the crude oil and the pure active constituents. The dark-coloured waste product contains 6·5 per cent. australol (phenol) and 25 per cent. aromatic aldehydes, principally cryptal, the remainder being sesquiterpenes, etc. The active constituents when tested by the Rideal-Walker method have high germicidal values. The crude oil when emulsified with rosin soap has a coefficient of 6·5, and forms a cheap and powerful disinfectant.—A. R. **Penfold** and F. R. **Morrison**: The essential oil of *Eriostemon Crowei* (*Crowea saligna*). This tall shrub, found on the rocky sloping banks of creeks and rivers in the Sydney district, yielded 0·4 of an oil heavier than water; the principal constituent (90 per cent.) was a new phenol ether, for which the name "croweacin" is proposed. Its molecular formula is $C_{11}H_{12}O_3$, and it contains one methoxy group. On oxidation with potassium permanganate it yields a neutral body, $C_{11}H_{14}O_5$, of M.P. 93° C., and an acid, $C_9H_8O_6$, of M.P. 153° C.—M. B. **Welch**: A method of identification of some hardwoods. In search of an accurate method of identifying certain hardwood timbers, particularly the Eucalypts, extracts obtained by boiling a definite weight of shavings in a known volume of water were examined. Various reagents, such as ferric chloride, lime-water, etc., were added to the extract, and a comparison made between similar timbers. The method does not give results with certainty.—M. B. **Welch**: The resinous exudation of rosewood. The resinous exudation or "sweating" which destroys the polish of rosewood is due to numerous minute drops of oil in certain parts of the wood. A steam distillation of shavings gave a yield of more than 3 per cent. of a bluish-coloured oil. Sweating is apparently due to lack of seasoning, or to polishing a freshly prepared surface.—W. S. **Dun** and Sir Edgeworth **David**: Notes on the occurrence of Gastrioceras, at the Irwin River Coalfield, W.A., and a comparison with the so-called Paralegoceras from Letti, Dutch East Indies. *Gastrioceras Jacksoni* occur in the Gascoyne River district, W.A., in a very well-marked horizon in the Lower Marine Permian beds, which has been traced for more than 20 miles. A new form is identical with Haniel's *Paralegoceras sundaicum* from the Permian of the Island of Letti. This is associated with a brachiopod fauna of a definite Asiatic Permian facies, and it will thus be possible to attempt a more definite correlation of the Western Australian beds with the Permian of Asia and Eastern Europe.—W. R. **Browne** and W. A. **Greig**: On an olivine-bearing quartz-monzonite from Kiandra, N.S.W. An explanation of the very rare association of the two minerals olivine and quartz in the same igneous rock. The chemical composition of the rock is given.—W. R. **Browne**: Note on the occurrence of calcite in a basalt from the Maitland district, N.S.W. An account of a basalt containing about 15 per cent. of interstitial calcite, which is believed to be the result, not of surface alteration, but of deposition from magmatic waters during the crystallisation of the rock.—J. K. **Murray**: Notes on the bacteriological aspect of pasteurisation of milk for cheddar cheese-making. Pasteurisation, coupled with the use of a good starter, greatly favours those bacteria which produce a cheese of good flavour and aroma. The "pasteurised" cheese was better in flavour and aroma than the "raw" check cheese and did not markedly lose in texture or body. Its vitamin content is not considered to be in any marked degree different from that of the ordinary "raw" cheese.

MELBOURNE.

Royal Society of Victoria, December 14.—Mr. F. Wisewould, president, in the chair.—F. **Chapman** and I. **Crespin**: The Austral Rhynchonellacea of the "nigricans series" with a description of the new genus Tegulorhynchia. The forms of the "nigricans series," fossil and recent, in the southern hemisphere, which have been referred to the boreal genus Hemithyris, constitute a distinct zoological group Tegulorhynchia. The Cainozoic species of Tegulorhynchia have probably evolved from a Jurassic form like that of Burmirhynchia, without the intervention of the Cyclothyris type, which was so predominant in the Cretaceous of Europe. The direct line of descent is probably from the European type *Burmirhynchia variabilis*. The bathymetrical distribution of the forms living in southern waters has been found to be of value in comparing the stratigraphical characters of the fossil series.—J. R. **Tovey** and P. F. **Morris**: Contributions from the national Herbarium of Victoria, No. 3. The paper contains a description of a new species, *Kunyea sulphurea* Tovey and Morris, from West Australia, and records of new regional distribution of native and introduced plants. A new introduction, *Tradescantia fluminensis* Vell. (Water Spiderwort), is recorded and also some additions to the introduced flora of Coode Island.—H. S. **Baird**: The occipital bones of the Dipnoi. Sections of the exoccipital bone of Ceratodus, and comparison with a developmental series of Lepidosiren, show no evidence of endochondral ossification. It appears probable that the endochondral method of ossification—a phylogenetically more highly developed mode of bone formation—does not exist in the Dipnoi.—G. **Horne**: Aboriginal cylindro-conical stones. Cylindro-conical stones are found in the Darling district and West to L. Eyre. They are unknown by the Darling blacks; also by all except a few old men of L. Eyre tribes. These call them uncanny, being the petrified penis of one circumcised with a firestick before the moora introduced the knife. Afterwards the stones must be lost. Circumcision was unknown where the stones most abound.

Official Publications Received.

Académie des Sciences (Česká Akademie Věd a Umění). Bulletin International. Résumés des travaux présentés. Classe des Sciences mathématiques, naturelles et de la Médecine. 18e année (1913). Diary of Societies.

SATURDAY, MARCH 3.

ASSOCIATION OF TECHNICAL INSTITUTIONS (Annual General Meeting) (at Carpenters' Hall), at 11 and 2.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (3).

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.—Dame Helen Gwynne-Vaughan: The Mechanism of Inheritance.

MONDAY, MARCH 5.

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.—The Absolute Measurement of Magnetic Force. Chairman, Dr. C. Chree. Speakers: F. E. Smith, Sir Arthur Schuster, H. Spencer Jones (and possibly Dr. A. Crichton Mitchell).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Evolution and Disorders (1) (Hunterian Lectures).

SOCIETY OF ENGINEERS, INC. (at Geological Society), at 5.30.—A. S. E. Ackermann: The Physical Properties of Clay (fifth paper) and the Dynamics of Pile-driving.

INSTITUTION OF RUBBER INDUSTRY (at Engineers' Club, 39 Coventry Street), at 6.30.—H. Savage: Telegraph Cable Manufacture, Rubber and Gutta-percha.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—J. H. Parker and others: Discussion on Control in Industry.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—E. S. Russell: Psycho-biology.

ROYAL SOCIETY OF ARTS, at 8.—J. E. Sears: Length Measurement (1) (Cantor Lectures).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Engineers' Club, 39 Coventry Street), at 8.—Dr. T. M. Legge: Industrial Poisoning and the Works Chemist.

TUESDAY, MARCH 6.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Arthur E. Shipley: Life and its Rhythms (2). Rhythm in Living Organism.

ROYAL SOCIETY OF ARTS (Dominions and Colonies Section), at 4.30.—Major E. A. Belcher: The Dominion and Colonial Sections of the British Empire Exhibition.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. G. Evans: The Nature of Arterio-sclerosis (1) (Goulstonian Lectures).

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—H. G. Cannon: A Note on the Zoea of the Land-Crab, *Cardisoma armatum*.—Miss L. E. Cheesman: Notes on the Pairing of the Land-Crab, *Cardisoma armatum*.—Dr. C. F. Sonntag: The Comparative Anatomy of Tongues of the Mammalia. VIII. Carnivora.—R. Kirkpatrick: A New Species of the Tunicate *Rhizomolgula* with remarkable Sensory Organs. No. 24. Results of the Oxford University Expedition to Spitsbergen, 1921.—T. H. Ring: The Elephant-Seals of Kerguelen Island.

INSTITUTION OF CIVIL ENGINEERS, at 6.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—K. C. D. Hickman: An Electric Indicator for Washing-troughs.—A. C. Banfield: The "Perfect" Camera.

RÖNTGEN SOCIETY (at Institution of Electrical Engineers), at 8.15.

WEDNESDAY, MARCH 7.

INSTITUTE OF METALS (at Institution of Mechanical Engineers), at 10.—Dr. Aitchison: The Mechanical Properties of the Magnesium Alloys.—Prof. H. C. H. Carpenter and C. C. Smith: Tests on Work-hardened Aluminium Sheet.—Kathleen E. Bingham and Dr. J. L. Haughton: The Constitution of some Alloys of Aluminium with Copper and Nickel.—M. Cook: The Recrystallisation of Cold Worked Cadmium.—Dr. A. W. Gray: Volume Changes accompanying Solution, Chemical Combination, and Crystallisation in Amalgams.—At 2.30.—Dr. W. Rosenhain, S. L. Archbutt, and S. A. E. Wells: The Production and Heat-Treatment of Chill Castings in an Aluminium Alloy ("Y").—Prof. F. C. Lea, Dr. V. A. Collins, and Dr. E. A. F. Reeve: The Modulus of Direct Elasticity of Cold-drawn Metals as a Function of Annealing Temperature.—A. M. Portevin: The Structure of Eutectics.—R. Genders: The Extrusion Defect in Brass Rods extruded from a Multiple Die.—S. Beckinsale: Further Studies in Season-Cracking and its Prevention. The Removal of Internal Stress in 60:40 Brass.

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS (at the Middlesex Guild-hall, Westminster), at 3.—Annual Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Evolution and Disorders (2) (Hunterian Lectures).

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—H. Morris-Airey: Development of Naval High Power Valves.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—A. Lucas: The Examination of Firearms and Projectiles.—R. C. Frederick: The Interpretation of the Results obtained in the Analysis of Potable Waters.—S. B. Phillips: Determination of the Purity of Vanillin.

ROYAL SOCIETY OF ARTS, at 8.—Prof. E. P. Stebbing: The Forests of Russia.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

THURSDAY, MARCH 8.

INSTITUTE OF METALS (at Institution of Mechanical Engineers), at 10.—R. C. Reader: Some Properties of the Copper-Rich Copper-Aluminium Alloys.—C. R. Austin and A. J. Murphy: The Ternary System Copper-Aluminium-Nickel.—Col. N. T. Belaiew: The Inner Structure of the Crystal Grain as revealed by Meteorites and Widmanstatten Figures.—A. L. Egerton and W. B. Lee: Separation of Isotopes of Zinc.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—Prof. A. E. H. Love: Some Electrostatic Distributions in Two Dimensions.—J. P. Gabbatt: A Hyperspatial Analogue of Feuerbach's Theorem.—Prof. G. H. Hardy and E. C. Titchmarsh: Solutions of some Integral Equations considered by Bateman, Kapteyn, Milne, and Littlewood.—S. C. Dlar: Some Integral Equations connected with the Elliptic Cylinder Functions.—J. Vinogradow: Lattice Points in Regions of two or three Dimensions.—M. Merker: Génération et étude d'une surface du 3e ordre particulière.—H. W. Turnbull: The General Symbolic Notation for the Principle of Duality and its Application to Determinants.—E. W. Hobson: On Generalised Fourier Series.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. G. Evans: The Nature of Arterio-sclerosis (2) (Goulstonian Lectures).

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), at 5.30.—Dr. Sonntag and others: Discussion on The Vagus and Sympathetic Nerves and their Relation to Hydrology and Climate.

SOCIETY OF DYERS AND COLOURISTS (London Section) (at Dyers' Hall, Dowgate Hill), at 7.—B. Brown and H. Jordan: The Valuation of Dye-stuffs by Titration Methods. (Rapid Commercial Estimation of Value.)

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—H. Dennis Taylor: Optical Designing as an Art.—T. Smith: The Distribution of Correction Duties in Optical Instruments.

INSTITUTE OF METALS (London Local Section) (at Institute of Marine Engineers), at 8.—Open Discussion.

CAMERA CLUB, at 8.15.—H. Main: A Pilgrimage to Provence.

FRIDAY, MARCH 9.

ROYAL ASTRONOMICAL SOCIETY, at 5.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5.—Sir William Bragg: The Crystalline Structure of Anthracene.—Dr. A. B. Wood and Capt. H. E. Browne: A Radio-acoustic Method of locating Positions at Sea.—J. H. Powell and Dr. J. H. T. Roberts: The Frequency of Vibration of Circular Diaphragms.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Condition and Disorders (3) (Hunterian Lectures).

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society of London), at 6.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at Engineers' Club), at 7.—J. G. Clark: Gas as a Fuel.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—R. C. D. Fell: Rolling Mill Machinery.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—W. Sanderson: Over the Gemmi to the Valley of the Rhone.

INSTITUTE OF CHEMISTRY at 8.—E. J. MacGillivray: Some Aspects of the Law of England affecting Chemists.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. C. W. Saleeby: Sunlight and Disease.

SATURDAY, MARCH 10.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (4).

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3—Conversazione.

PUBLIC LECTURES.

SATURDAY, MARCH 3.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss M. A. Murray: Legends of the Gods of Ancient Egypt.

MONDAY, MARCH 5.

VICTORIA LEAGUE HOUSE (22 Eccleston Square, S.W.1), at 5.—P. D. Warren: Peeps at Ceylon Life, Industries, and Vegetation.

OVERSEAS CLUB AND LEAGUE (at Vernon House, Park Place, S.W.1), at 8.—W. R. Dunlop: The Work and Aims of the West Indian Agricultural College, Trinidad.

TUESDAY, MARCH 6.

LONDON SCHOOL OF ECONOMICS, at 5.—A. W. Flux: Statistics, before, during, and after the War: Prices.

SCHOOL OF ORIENTAL STUDIES, at 5.—Sir E. Denison Ross: Early European Intercourse with the East.

WEDNESDAY, MARCH 7.

UNIVERSITY COLLEGE, at 5.—Dr. A. H. Drew: The Cultivation of Tissues in Vitro (2). (Succeeding Lecture on March 14.)

KING'S COLLEGE, at 5.—Sir Herbert Jackson: Some Thoughts on the Relations of Science and Industry.

THURSDAY, MARCH 8.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 5.—W. Bayes: Painting and Architecture.

SATURDAY, MARCH 10.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. N. Milligan: The Great Sea-serpent.

THE GROCERS' COMPANY'S RESEARCH SCHOLARSHIPS.

With the object of encouraging original research in SANITARY SCIENCE, the Grocers' Company offer THREE SCHOLARSHIPS, each of £300 a year, with an allowance to meet the cost of apparatus and other expenses in connection with the work, tenable for one year, but renewable for a second or third year, subject to the conditions of the scheme under which they are established.

The next election will take place in May 1923.

(One Scholarship vacant.)

Applications must be sent in before April 1 to the CLERK of the GROCERS' COMPANY, Grocers' Hall, London, E.C.2, from whom a form of application and further information may be obtained.

BEDFORD COLLEGE FOR WOMEN (UNIVERSITY OF LONDON).

POST-GRADUATE SCHOLARSHIP IN SOCIOLOGY.

The Council of Bedford College for Women invite applications for the above scholarship. Value £150 for one year. Open to women only.

For further information apply THE SECRETARY, Bedford College, Regent's Park, N.W.1.

BEIT FELLOWSHIPS FOR SCIENTIFIC RESEARCH.

NOTICE is hereby given that the TENTH ELECTION OF FELLOWS will take place on or about July 16, 1923.

Applications must be received on or before April 19, 1923.

Forms of application and all information may be obtained by letter, addressed to the RECTOR, Imperial College, South Kensington, London, S.W.7, England.

COUNTY OF ESSEX.

EAST ANGLICAN INSTITUTE OF AGRICULTURE, CHELMSFORD.

Appointment of Assistant Lecturer in Agricultural Chemistry.

The Essex Agricultural Committee invite applications for the post of ASSISTANT LECTURER in AGRICULTURAL CHEMISTRY at the East Anglican Institute of Agriculture, Chelmsford.

The salary will be £350 per annum, rising by annual increments of £20 to £450, and the position will be held during the pleasure of the Council, and be subject to termination by three months' notice.

Canvassing of members of the Committee or the County Council is forbidden.

Forms of application may be obtained from me, and applications accompanied by copies of not more than three recent testimonials (which will not be returned) must reach me not later than March 15, 1923.

JOHN H. GOOLD,
Clerk of the Essex County Council.

Shire Hall, Chelmsford.
March 1, 1923.

UNIVERSITY OF BRISTOL.

The University invites applications for the following Grade III. posts which will be vacant on August 1, 1923:

ASSISTANT LECTURER IN ZOOLOGY
ASSISTANT LECTURER IN CHEMISTRY (ORGANIC)
} Salary £300 per annum.

Applications should be lodged with the REGISTRAR, from whom further particulars are available.

March 3, 1923.

UNIVERSITY OF DURHAM.

ARMSTRONG COLLEGE, NEWCASTLE-UPON-TYNE.

CHAIR OF PHILOSOPHY.

The Council of Armstrong College invites APPLICATIONS for this CHAIR. Salary £800 per annum. Appointment to date from October 1, 1923.

Ten copies of applications and of not more than three testimonials must be received by the undersigned by May 1, 1923.

Further particulars on application.

J. Y. T. GREIG,
Registrar.

VACANCY for MATHEMATICAL AND SCIENCE MISTRESS in first-class Girls' School (Lancs.). 100 boarders. Maths. to Scholarship standard. £150 resident. HOOPERS (Educational Agents) Ltd., 361 Oxford Street, London, W.1.

BOARD OF TRADE, STANDARDS DEPARTMENT.

A vacancy exists for an ASSISTANT EXAMINER in the Standards Department of the Board of Trade with establishment in H.M. Civil Service after two years' approved service. The duties are mainly in connection with the examination of weighing and measuring apparatus of novel types with a view to their approval for use in trade.

Candidates, who must be British subjects by birth, and the sons of fathers also British subjects by birth, should possess a University Degree (or its equivalent) in Science or Engineering, and should have had practical workshop experience. Preference will be given to ex-service men.

The salary is £150, rising by £15 to £300 per annum, with bonus which is re-assessed half-yearly on the basis of the average cost-of-living figure for the previous six months. The present bonus on £150 is £94 : 14s., making the total remuneration £244 : 14s.

Applications with copies of testimonials should be made in writing to the PRINCIPAL ESTABLISHMENT OFFICER, Board of Trade, Great George Street, Westminster, S.W.1, not later than March 17, 1923.

MINISTRY OF AGRICULTURE AND FISHERIES

Applications are invited for an appointment as INSPECTOR in connection with Agricultural and Horticultural Education and Research.

Candidates must be not less than twenty-five years of age, and in addition to having taken a course in Science or Agriculture at a University or Agricultural College should have had a special training in the science and practice of Dairying.

Salary £250 per annum rising to £400 per annum, plus Civil Service Bonus.

Preference will be given to ex-service applicants.

Forms of application and copies of the regulations affecting these appointments can be obtained from the SECRETARY, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1.

Application forms must be returned not later than March 26.

UNIVERSITY OF LONDON.

The Senate invite applications for the following UNIVERSITY READERSHIPS tenable at Bedford College:

READERSHIP in GEOGRAPHY, salary £700 a year.
READERSHIP in MATHEMATICS, salary £500 a year.

Applications (12 copies) for either post must be received not later than first post on April 13, 1923, by the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7, from whom further particulars may be obtained.

UNIVERSITY OF LONDON.

The Senate invite applications for the RAMSAY MEMORIAL CHAIR of CHEMICAL ENGINEERING tenable at University College. Full particulars may be obtained from the ACADEMIC REGISTRAR, University of London, South Kensington, London, S.W.7.

UNIVERSITY COLLEGE OF WALES.

ABERYSTWYTH.

(One of the Constituent Colleges of the University of Wales.)

DEPARTMENT OF PURE MATHEMATICS.

Applications are invited for the post of ASSISTANT LECTURER in PURE MATHEMATICS under Professor W. H. Young, F.R.S., for the Session commencing October 1923. Evidence of ability in undertaking research in Analysis and Geometry will be required. Salary £300.

Applications should reach the undersigned (from whom further particulars may be obtained) not later than March 23.

C. G. BURTON, General Secretary.

THE ROYAL TECHNICAL COLLEGE, GLASGOW.

The Governors invite applications for the CHAIR of ELECTRICAL ENGINEERING, from which Professor Magnus Maclean, M.A., D.Sc., LL.D., is about to retire. Salary £1000.

Applications and testimonials should be sent, not later than March 22, to the DIRECTOR of the College, from whom further particulars may be obtained.

TRADE JOURNALISM—Wanted on editorial staff of firm of technical publishers, young chemist (not over 25) of public school and college training and some journalistic experience. Knowledge of photographic processes and apparatus an advantage. Applicants are asked to state fully record at school and college and subsequent occupation. Photograph and specimens of literary work may be sent and will be returned. Write Box 727, REYNELL'S, 44 Chancery Lane, W.C.2.

M.Sc., GEOLOGY, CHEMISTRY, age 28, four years' war service, desires post, anything, anywhere. Box 62, c/o NATURE Office.

EXCITING SEA EXPEDITION—Vacancies for scientific men. Capital essential. LEGION, 6 Adam Street, Adelphi, London, W.C.2.

Preservation and Restoration.

ONE of the most important services which science can render to mankind is in the discovery of the precise origin of corrosion and decay brought about by natural causes and of methods of counteracting the destructive agencies. It becomes increasingly important to man to preserve, during such times as he may desire, the material fruits of his labour in their original form. Foodstuffs must be preserved during periods of plenty and during transportation to lands where they are scarce; structures of wood, metal and stone must be safeguarded from the destruction caused by living organisms, water, frost, and the atmosphere; fabrics must be protected from the deterioration brought about by light and bacteria. The annual monetary loss due to our lack of knowledge of the mechanism and counteraction of the phenomena involved is enormous and, in fact, incalculable.

For evidence of our ignorance in such matters it is only necessary to look at the stonework of almost any ancient building; a cursory examination of some of our modern buildings will indeed suffice. Is it impossible completely to protect and preserve stone from decay and destruction? Is the vast annual sum spent in protective paints for iron and steel structures really essential expenditure? Such questions as these are at present unanswerable, but they are unlikely to remain so if adequate scientific research be directed to the problems so obvious to every one. Brearley's discovery of stainless steel, important as it is, is but a minor success in such a wide field, for the use of this material is greatly restricted by its price. Nevertheless, the discovery encourages the belief that, so far as metals are concerned, the broader problems are not insoluble.

Individually, the problems of corrosion and decay are not very attractive to the independent research worker of the present day; the lure of more recondite fields of research is generally too powerful. But viewed collectively these problems are so important economically, and so far-reaching, as to call for co-ordinated investigation on a wide scale. In such investigations Government can and should play a valuable part as an organising and directing agency, and it is satisfactory to note the steps already taken in this country to initiate and to subsidise the necessary research. Perusal of the last Report of the Advisory Council for Scientific and Industrial Research (see NATURE, February 3, p. 165) shows that in addition to the assistance given to two professional bodies in aid of researches on special types of corrosion, the Department is carrying out several kindred inquiries under its own direction. Grants have been made to the Institute of Metals for

the investigation of the corrosion of condenser tubes and of aluminium, and to the Institution of Civil Engineers for a research upon the deterioration of structures in sea-water. In direct association with the Department is the Food Investigation Board, which is dealing with the fundamental problems of food preservation. The Fabrics Research Committee and the Forest Products Research Board are interested in the protection of fabrics and woods respectively from decay, and we understand that a committee has recently been formed to inquire into methods of preserving stonework. Finally, by means of the laboratory which has been set up at the British Museum, the Department has provided for research into the causes and prevention of corrosion and decay occurring in museum specimens. Though each of these organisations has its own specific ends in view, judicious co-ordination of their efforts and intercommunication of the results they obtain will doubtless be of great assistance to the general progress.

A second report[1] on the investigations in progress at the British Museum has recently been published, and its appearance could scarcely be more opportune. The information it gives will be of great value to the curators of museums of antiquities and, we imagine, will be specially welcome to those who are engaged in the responsible and delicate task of recovering the archæological treasures of King Tutankhamen's tomb.

Little scientific research directly bearing upon the preservation and restoration of museum specimens has been undertaken in the past. Too often have the attempts at restoration been left in the hands of museum workmen whose empirical efforts have in some cases ended admirably, in others disastrously. Successful methods so devised have sometimes jealously been guarded as "trade secrets" guaranteeing continuity of employment. Such an unsatisfactory state of affairs cannot continue; if it is our duty—and indubitably it is—to preserve for future generations the evidences of past phases in the life of mankind, then it is essential that knowledge of trustworthy preservative processes should be communicated freely to all concerned. It is gratifying that Great Britain should take the lead in instituting scientific research of a very high order in this direction, and in publishing the results for the general benefit of all who are possessors or curators of valuable antiquities.

The Department has admittedly been very fortunate in enlisting Dr. Alexander Scott as director of the investigations which are being conducted at the British Museum laboratory. His second report, like its predecessor, shows abundant evidence of the high degree of experimental resource required in work of this kind, and of the very fragile character of many of the objects which he has successfully restored and protected from further deterioration. But in Dr. Scott the fears and caution of the antiquary are tempered by the confidence born of scientific knowledge; as a result of this happy combination we have on record the solutions to a number of problems which have long been a source of anxiety to museum curators. Prints and pictures, and objects of stone, silver, iron, lead, copper, bronze, and wood have all been brought to Dr. Scott for treatment, and subsequently have been returned to their places in the museum restored and insured against further attack.

The work at the British Museum laboratory has hitherto, naturally, been chiefly of a chemical character. But many museum problems have a microbiological aspect. The cellulose-destroying moulds and bacteria, for example, must play an important part in the decay of fabrics, paper, and other materials in museums; in time, doubtless, the laboratory will be able to turn its attention to these problems. Reference to such a development suggests the interesting possibilities which would be involved in a microbiological examination of the fabrics and cellulosic débris found in King Tutankhamen's tomb. Even though the examination proved negative so far as the discovery of spores of bacteria and moulds is concerned, valuable information would be yielded by the decayed material itself, for it is now known that cellulose fibres which have been attacked by such organisms show characteristic markings. We strongly hope that facilities will be given for such an examination to be made before the material has become infected with present-day organisms.

Attention should be directed to a feature of Dr. Scott's report unusual in Government publications, the excellent collotype illustrations; these supply striking visual confirmation of the successes he describes.

Physiology in Medicine.

The Heart as a Power-Chamber: a Contribution to Cardio-Dynamics. By Dr. Harrington Sainsbury. (Oxford Medical Publications.) Pp. xii+248. (London: Henry Frowde and Hodder and Stoughton, 1922.) 12s. 6d. net.

IF we compare the text-books of physiology of to-day with those of twenty years ago, we cannot fail to be impressed, not only with the vast strides that have been made by the subject within this short time, but also with the fact that a large majority of the latest discoveries, which have an intimate bearing on the understanding and control of disease, could not figure

at all in the physiological equipment of the men who studied medicine at that time and are now in the full tide of practice. Even the professional physiologist finds it difficult to keep himself abreast of the course of discovery in his own subject. It would seem, therefore, almost impossible to expect a man in a busy practice to appreciate what recent physiology has done and is doing for his science and for his craft. Many men, and those not the least successful, do not attempt the task, and trust to their craftsmanship and their powers of naming a diseased condition, that is, of placing it in a category familiar to them which they therefore believe they understand, and to their experience in treating such cases without, at any rate, harming the patient.

At the present time the condition is improved by the establishment of clinical units, of which the heads have time and opportunity, not only to advance their own subject, but also to keep abreast of the more important researches in the collateral sciences, so that they may serve to some extent as interpreters of the latter to their professional brethren. But even for the practitioner who is not so fortunately situated the task is not so impossible, if his training in physiology has been of the right character and has fallen on favourable soil. In the physiological training of the student it is not collections of facts or strings of arguments which are of supreme importance, but the method by which these facts are attained and the attitude of mind of the investigator. If he can carry this method and this attitude of mind into the wards, every case becomes for him a physiological experiment. Diagnosis is not the application of some appropriate label, but an understanding of what is happening in the body and how the disorder of any given function has come into existence. The whole of his practice becomes a research, and with one problem after another crying out for solution his attention and his curiosity are kept awake for any light which may be thrown by physiology or other science on the questions with which he has to deal. The true scientific physician must remain a physiologist during his whole life.

In the work under review Dr. Sainsbury shows that he has not forgotten the lessons in physiological method and thinking that he learned with Sidney Ringer. Taking as his text the action of the heart and the modifications that this may undergo in disease, he endeavours from his pathological and clinical experience to reconstruct the conditions in the living organism and, as he says, "to visualise the organs and tissues dynamically." He shows that in every case the test of structure must be the functional adequacy of the tissue. Given a case of heart disease the important thing is not an intimate analysis of the heart sounds and their modifications, but the knowledge of what the heart can do, and what are its powers as a pump, *i.e.* in maintaining the circulation of the blood.

In the first chapter, on the anatomical relations of the heart, the author gives an interesting series of measurements of the relative weights of the different parts of the heart, and shows that the muscular tissue surrounding each cavity is roughly proportional to the work that the cavity has to do in the maintenance of the circulation of the blood. Thus the muscular tissue of the auricles is roughly only one-tenth of that of the two ventricles, while the muscular tissue of the right ventricle as compared with that of the left ventricle is a little less than one-third of the latter ($1-2{\cdot}5$). In this case there would seem to be a discrepancy between the mass of the muscle and the actual work done by each cavity. It is probable that the work of the left heart is five or six times as great as that of the right ventricle. The smaller difference in the muscular tissue may be due to the greater mechanical disadvantage attendant on the arrangement of the muscular fibres of the right ventricle.

When we consider the enormous strain that may be thrown upon the walls of the left ventricle during exercise it is astonishing to find that one part of its wall, namely, that of the extreme apex, is only a few millimetres thick. Dr. Sainsbury points out that the heart would tend to rupture at this point if it had to sustain the full pressure of the blood during the ventricular systole. He suggests that at the very beginning of systole the blood is squeezed out from the apex by the preliminary contraction of the vortical fibres at this spot. As a matter of fact, Lewis has shown that the vortex of the left ventricle is one of the places where the wave of negativity preceding contraction appears earliest, though the time is short which elapses between the appearance of the wave at the apex of the ventricle and that at other parts of the two ventricles. It must be owned that electrical measurements give no support to the further hypothesis of the author, namely, that the circular band of fibres surrounding the left ventricle must contract later than the spiral fibres.

Attention is directed to a fact which often escapes notice, namely, the large size of the aorta and big veins as compared with the heart. Here we have a pump putting out about 4 oz. of blood at each stroke into a vessel 1¼ inches in diameter, and the big veins entering the heart have a total cross-section even larger. We should be almost justified in speaking, therefore, of an arterial sac and a venous sac, each serving as a reservoir of blood to supply the arterial system and the heart respectively.

It is always difficult to judge of the relative value of results obtained by different methods in a science with which one is not in daily contact. In Dr. Sainsbury's

account of the venous pulse he raises difficulties which are really due to the attempt to make a minute comparison between the results of two methods, one of which is accurate to one-thousandth of a second, and the other only to one-twentieth of a second. By the optical method we can obtain very accurate records of the intra-auricular pressure. These show small elevations of pressure, one due to the contraction of the auricle, the second to the beginning of the ventricular systole and the sharp closure of the auriculo-ventricular valves, and the third to the accumulation of blood in the auricle during the continued contraction of the ventricle. A tracing of the venous pulse in the neck taken with a polygraph also shows three elevations which must have a similar causation. The middle one has been called the 'carotid pulse' by Mackenzie, and was ascribed by him to the pulse in the carotid transmitted to or through the jugular vein. This extraneous element in the venous pulse may possibly be often present in the tracings taken by this method, but it is really of not much importance whether it is external or whether it is due to the propagation of the wave of pressure which occurs in the auricle at the beginning of systole. Within the limits of error of the apparatus the 'c' wave may serve to mark the beginning of the ventricular systole, since it occurs either at the very beginning or within two-hundredths of a second afterwards.

In his description of 'tone' as applied to the heart, the author, in common with many clinicians and guided by the physiology of a few years ago, takes a view which I believe is erroneous. He describes tone as resistance to distension and therefore as a property which comes into play during diastole to prevent over-distension of the heart. Such a property would hinder rather than further the action of the heart pump. The filling of the heart is determined by the inflow. If the inflow increases, the rate of the heart (in the intact animal) increases *pari passu* so that this organ shall not be too distended. To prevent over-distension the strong fibrous sac of the pericardium is provided. It is important that the heart during diastole should present as little resistance as possible to distension, since any resistance would cause a rise of venous pressure and impede the circulation. If we examine the clinician's idea of a heart with good tone, we find he is really speaking of a heart with good contractile power, *i.e.* one which contracts strongly and empties itself, or nearly so, at each beat. The 'tone' would be measured rather by the systolic volume than by the diastolic volume of the heart. The term, however, is so ambiguous and has given rise to so much confusion that it would be better not to employ it at all in connexion with the heart.

There are certain other points which one might criticise, such as the part ascribed to the capillaries in the maintenance of the normal resistance of the circulation, as well as the mechanism of the absorption of drugs administered subcutaneously. But it is on account of its point of view that Dr. Sainsbury's book is useful and can be recommended to students. It might, indeed, be set to senior students as a subject of commentary and criticism from a physiological standpoint. If they could take the habit of mind of the author with them into the wards, their training in physiology would not have been in vain. E. H. STARLING.

Normal and Abnormal Psychology.

(1) *Beyond the Pleasure Principle.* By Dr. Sigm. Freud. Authorised translation from the Second German edition by C. J. M. Hubback. (The International Psycho-Analytical Library, No. 4.) Pp. v+90. (London: G. Allen and Unwin, Ltd., 1922.) 6*s.* net.

(6) *Remembering and Forgetting.* By Prof. T. H. Pear. Pp. xii+242. (London: Methuen and Co., Ltd., 1922.) 7*s.* 6*d.* net.

(1) PROF. FREUD'S "Beyond the Pleasure Principle" is not a long essay; but it is exceedingly difficult to read, not only because of the style in which it is presented, but also on account of the philosophical ideas which the author attempts to express. It is packed full of observations, theories, and extensions of theories of great interest and originality.

The reader will not always, perhaps, be able to find himself in agreement with the argument; but he will certainly be stimulated to think. Originally, Freud's theory worked with fairly simple conceptions. The "pleasure-principle" emerged as a result of actual psychoanalytical practice. Any mental process

originates in a state of tension, which is unpleasant; and, in virtue of this principle, moves towards relaxation. There is a tendency towards stability. But this tendency is met and checked by a "reality-principle" to which the sane psyche must adjust itself. Nevertheless, in the long run this too makes for pleasure. But phenomena are observed—certain forms of play in children, dreams in cases of war-neuroses, etc.—which seem to indicate a compulsion to repeat unpleasurable experiences. These show in a high degree an instinctive character. Considering this repetition of unpleasant activity, Freud accordingly puts forward the speculation that instinct might be "a tendency innate in living organic matter impelling it towards the reinstatement of an earlier condition."

Developing this speculation, Freud reaches the conclusion that the goal of instinct, as of life itself, is death. Originally, again, psychoanalysts had drawn a sharp distinction between the "ego-instincts" and the "sex-instincts." How, then, could an "ego-instinct" such as that of self-preservation have death as its goal? The answer is found to be given in Narcissism. Self-preservation is in reality libidinous. The libido is turned upon the ego and, *pro tanto*, away from the object. Accordingly, instead of the old distinction between the "ego-" and "sex-instincts," a distinction is now drawn between the "life-" and "death-instincts." These have striven together for mastery from the very beginning of the emergence of life from the inorganic. The "pleasure-principle" marks the "life-instincts" with the universal tendency of all living matter, namely, to return to the peace of the inorganic world. The "reinstatement-compulsion" lies behind it as well as behind the "death-instincts" of the organism.

Freud advances other highly ingenious and interesting speculations in his essay, of which one is a theoretical account of the development of the nervous system, open to the assaults of the exterior world only through a limited number of special channels which protect it from the prodigious energy without. But this nervous system is unprotected from the instinctive forces which arise within the body. These are not "bound" but free-moving nerve processes striving for discharge; and they give rise to disturbances comparable to the traumatic neuroses.

(2) Brill's "Fundamental Conceptions of Psychoanalysis" consists of the lectures of a course given to students in pedagogics in the University of New York. It is an elementary presentation of the Freudian principles and doctrine, and deals with the familiar topics of psychoanalytic literature—forgetting, stammering, lapses, mistakes, dreams, etc. There is an interesting chapter on the only child, another on selections of vocations. The book is diffuse, of a free-and-easy style, and full of Americanisms. It is published in England, but the type and spelling suggest that the plates were cast in America.

(3) Most people come to an inductive science with metaphysical presuppositions of one kind or another. In "Studies in Psychoanalysis" Baudouin makes a protest against the spirit of the systematiser, which has "been the bane" of the subject. The first part of the work is taken up with theoretical exposition. The second consists of 207 pages of case histories given in detail. The beginner is well advised, in the translators' preface, to commence with the cases and read the theory afterwards. He will thus be in a better position to examine the inductions made by the author in the light of the facts.

Baudouin links up psychoanalytic theory with general psychology. He is an eclectic, accepting principles from authors of widely differing views, and adding to them views of his own. His most personal contribution to the practice of psychotherapeutics is his conjoint use of psychoanalysis and suggestion. He is averse to the practice of either alone. The employment of the two methods together has been much criticised, many analysts condemning it outright; nevertheless it is difficult to see how suggestion can be kept out of an analysis. As the author remarks, "transference" is an effective relationship between the analyst and the patient, in which the ideoreflexes of suggestion occur naturally. This appears to be so; and therefore a controlled use of suggestion would seem to be reasonable. The present forms of suggestion and of analysis grew in two parallel lines of development from a common origin. Psychoanalysis was, in the first instance, practised on subjects in the hypnotic state.

The histories of the cases given are interesting, and range from those of quite young children to adults. The book is well translated. A good glossary of psychoanalytical terms is provided, as well as a bibliography and a very complete index.

(4) Dr. T. W. Mitchell is president of the Society for Psychical Research, and in his work on medical psychology he discusses a number of facts derived from abnormal and pathological psychology with the view of throwing light upon "psychic" problems. The main topic treated is multiple personality—for the account given of the appreciation of time by somnambules and the case of hysteria described in detail really relate to this. An account is given of an interesting series of experiments carried out by the author, which consisted in the performance of post-hypnotic suggestions involving the appreciation of lapse of time on the part of the subject. Mitchell considers that, whether

we treat the data as orthodox men of science or transcendentally, there is a large residuum of unexplained phenomena. In view of the controversy alluded to above, it is interesting to note that Mitchell's hysterical patient, in whom several "personalities" developed, was ultimately cured, partially by analysis carried out in the hypnotic state, and partially by word-association tests in the waking state. Besides the study of this case, the well-known classical cases are recounted and discussed.

The latter chapter deals with body and soul. The author examines the various psycho-physical theories in connexion with abnormal and pathological states; and the existence of a transcendental "soul," as the substrate of consciousness, is put forward as a legitimate hypothesis by which to account for some of the striking phenomena of multiple personality. Thus straying into the "vaguer regions of transcendental speculation," the author strangely makes no mention of hylomorphism, into which theory the facts would seem to fit as well as into those of Plato or Descartes.

(5) A great deal has been written on the emotions, both from the point of view of their expression and from that of introspective description. But it is only recently that much experimental investigation has been devoted to them. Mr. Whateley Smith attacks the problem in an experimental manner; and his "Measurement of Emotion" is one of the pioneer steps in that direction. The author, using the psychogalvanic reflex, reaction times, and reproduction tests as indicative of emotional changes, carried out a series of experiments on fifty subjects in order to ascertain the effect of emotion upon memory. Measurements were taken for 100 reactions to stimulus words (modified Jung list), and a number of these words were later learned by heart and reproduced at intervals by the subjects. Thus a memory-value, to be correlated with the affective value of the words in question, was obtained.

It was found that affective tone is of two kinds, positive and negative, and that positively toned words tend to be remembered, while negatively toned ones tend to be forgotten. The galvanometer records both kinds of tone. Reaction times and failures in reproduction are, in general, signs of negatively-toned words. Reaction-word experiments were also carried out with subjects under the influence of alcohol. It was found in these cases that highly-toned reactions gained and moderately-toned ones lost; and that the reactions in general regressed towards an all-or-none, or protopathic, type. The research is a well-planned one, and some of the conclusions valuable not only in themselves, but also in their applications to other problems in psychology.

(6) Prof. Pear's work on memory is not an ordinary text-book on the subject. In the first place, it is a popular exposition, growing out of a nucleus of lectures originally delivered to officers of the R.A.M.C. on the normal functions of memory, intended to help them to estimate abnormalities in their patients. In the second place, its net is cast wide enough to include much that is usually not treated in formal discussions of the topic.

Pear deals with the nature of memory and the mechanism of remembering, as well as of the process of forgetting. There is an important chapter on the functions of the image, in which the question of "imageless thought" is treated, and much on dreams, their mechanism and analysis. This last has become very prominent of recent years in relation to memory in connexion with psychoanalysis. The book has appendices on synæsthesia, number-forms, muscular skill, and the significance for problems of memory of some recent experiments (Head's and Rivers's) on the nervous system. It is written in the characteristic breezy style of Prof. Pear, and should be of value as an easy introductory avenue to the subject of which it treats.

Carotin-like Colours in Plant and Animal Tissues.

Carotinoids and Related Pigments: the Chromolipoids. By Prof. Leroy S. Palmer. (American Chemical Society Monograph Series.) Pp. 316. (New York: The Chemical Catalog Co. Inc., 1922). 4.50 dollars.

TO all who are interested in the investigation of the colouring matters produced by Nature in the vegetable and animal kingdoms this work should be welcome. It forms one of a monograph series, being produced under the auspices of the American Chemical Society in accordance with an arrangement with the Inter-Allied Conference on Pure and Applied Chemistry which met in July 1919. The series will form a very valuable addition to chemical literature in the English language if all the volumes deal as thoroughly with their respective subjects as does this one.

The author restricts himself to red, orange, and yellow pigments which can be extracted from the tissues by fat solvents—the carotinoids and related colouring matters. The opening chapter contains a very necessary review of the nomenclature in use, in the course of which the various irregularities and overlappings that exist are clearly indicated and the methods of nomenclature used in the treatise itself is set out. This chapter is, of necessity, rather disjointed in character, and the section dealing with non-carotinoid plant pigments is poor. For the sake of convenience the author, when passing to the description of the carotinoids which

occur in plant life, adapts the subdivision of his field into carotinoids in Phanerogams (ch. ii.) and carotinoids in Cryptogams (ch. iii.). Although, as admitted by the writer, there is no logical reason for so doing, as the various pigments are widely distributed through Nature, this method of treatment has been worked up in an interesting manner and the interest deepens as each group is dealt with.

Passing from plant to animal life, the literature concerning the occurrence of carotinoid pigment in Vertebrates (ch. iv.) and Invertebrates (ch. v.) is surveyed. Later chapters deal with the very highly interesting problems concerning the chemical and biological relationships which may exist between plant and animal carotinoids; also with the ideas that have been put forward concerning the functions which carotinoids perform in plant and animal life.

Three chapters are devoted to the description respectively of the methods of isolation, the properties and methods of identification, and the quantitative estimation of carotinoids. Interesting plates show the crystal forms of several pigments of this group, also spectrophotographic records of their absorption bands. A summary follows each chapter.

A comprehensive bibliography is included, and followed by author and subject indexes—which, however, cannot be described as complete. It is unfortunate that in places careless phraseology is used, which considerably detracts from the pleasure of the reader. The volume contains a very large mass of information that will be invaluable to all investigators working in this field.

Paradoxical Science.

The Constitution of the Universe. (The Theory of Intersistence), dedicated to my Subscribers. By Louis Stromeyer. Pp. xx+255+xv. (Bangalore: Higginbothams, Ltd., 1922.) n.p.

MOST secretaries of local scientific societies (as well as many other people) have experience of the man who possesses the type of mind exemplified in this book: a mind as attracted by scientific hypothesis as a moth to a flame, and as wanting in discretion as the moth. The author is a mining engineer in India, and in his preface writes not without some modest sense of his temerity in composing this book and inducing a number of friends to finance its publication. A few words of apology, however, and particularly the confession that it has been written hastily and without opportunity to consult proper scientific literature, will scarcely excuse so hardy a piece of presumption. No man occupied with practical affairs, especially if his work is based on the application of physical science, like mining, would fail to adopt an attitude of severe disapproval towards an amateur who, while confessedly ignorant, proposed to reverse all the conclusions arrived at by men experienced in these affairs, and to substitute wholly new theories and methods; yet most practical arts are relatively simple, compared with the vast and complex structure of modern science, which these amateurs are eager to raze and rebuild. It is, indeed, remarkable that this obvious consideration should not prevent men, often capable and successful in their own work, from embarking on so foolish an enterprise, and imagining that they

> "Can tell us easy how the world was made,
> As if they had been brought up to the trade,
> And whether chance, necessity, or matter,
> Contrived the whole establishment of nature."

This book bears the typical marks of its class: a title of ample scope, chapter-headings of appropriate vagueness ("The Fundamentals," "Form and Posture," "Co-ordination," "Phases," etc.), arguments in an involved pseudo-philosophical style, and, as befits such a work at the present day, preoccupation with relativity and the magic name of Einstein. By request, the author has included a chapter specially devoted to the criticism of "modern theories"; it is surprising to find the bulk of this devoted to objections against a subject so relatively simple as the kinetic theory of gases and of matter generally.

The objections here raised (and they are typical of those brought forward elsewhere in the book) merely show, when examined, that the theories in question have proved difficult to the author's comprehension, and difficulties of this kind are probably the bond of union between the author and his supporters. There is nothing to be ashamed of in finding theories difficult to understand, especially if, as is often the case, they require an acquaintance with mathematics and a background of physical knowledge which are themselves only attainable by careful study. Such difficulties are by no means a mark of inferior ability: the late Lord Rayleigh, for example, mentioned at a British Association meeting some years ago that he had formed no opinion on a certain result in the theory of diffraction, obtained by Sommerfeld, because to appreciate the matter properly would require a fortnight's serious reading, which he did not feel ready to give to it. But in science, as in religion, there are some who by their own unaided powers

> "Will undertake the universe to fathom,
> From infinite down to a single atom.
>
> . . . . . .
>
> And, where they've least capacity to doubt,
> Are wont t' appear most perempt'ry and stout."

One is tempted, indeed, to go on quoting Samuel Butler, who, whatever the quality of his rhymes, summed up the truth of this matter in a few caustic passages. For language adequate to describe the obscurity and tedium of such books one would need the powers of a Swift or a Pope.

Our Bookshelf.

(1) *A New Manual of Logarithms to Seven Places of Decimals.* Edited by Dr. Bruhns. Thirteenth Stereotype edition. Pp. xxiv+610. (London: Chapman and Hall, Ltd., 1922.) 12*s.* 6*d.* net.

(2) *Tables of* $\sqrt{1-r^2}$ *and* $1-r^2$ *for Use in Partial Correlation and in Trigonometry.* By Dr. J. R. Miner. Pp. 49. (Baltimore, Md.: The Johns Hopkins Press, 1922.) 1 dollar.

(3) *Two-figure Tables.* Compiled by C. R. G. Cosens. On Card, 10 in. × 4¾ in. (Cambridge: Bowes and Bowes; London: Macmillan and Co., Ltd., n.d.) 6*d.* Quantities of one or more dozens supplied at 4*s.* per dozen.

(1) THE first table in this edition of Dr. Bruhns' Manual is a reprint of Köhler's table of logarithms of integers from 10000 to 100000, covering 180 pages. Auxiliary tables of proportional parts at the side of each page give all necessary assistance to a computer in finding the logarithms of six- and seven-figure numbers. Eight-figure logarithms of integers between 100000 and 108000 are not given, as in the original Köhler and the modern Chambers, "since the addition of logarithms of numbers from 100000 to 108000 does not appear to offer a sufficient advantage." With this we do not agree. Eight places of decimals in logarithmic work in dealing with numbers that slightly exceed 1·0 are only equivalent to seven places for numbers in the neighbourhood of 9·0. Within recent years the present reviewer was engaged in computing work in which the eight-figure logarithm was essential for numbers just greater than 1·0. In fact it was only regretted that the eighth figure was not available from 100000 to 115000.

There follow tables of the logarithms of $\sin x$, $\cos x$, $\tan x$, and $\cot x$, the entries being given at intervals of one second from $x=0°$ to $x=6°$, and at ten-second intervals from 6° to 45°. In the latter range six pages are assigned to each degree of arc, whereas one page is given to each minute from 0′ to 10′. The tables of differences and proportional parts on each page give every help needed in interpolation.

A few minor tables are added to the above main ones. The tables on each page are set out in an attractive way, and the new edition will be found to be a very serviceable one.

(2) The tables in this pamphlet give the numerical values of $\sqrt{(1-r^2)}$ and $1-r^2$ to six decimal places for values of r between 0·0 and 1·0 at intervals of 0·0001. Differences and subsidiary tables for interpolation are not appended. Thus the table gives the consecutive entries

$$\sqrt{(1-r^2)}=0{\cdot}567026 \text{ when } r=0{\cdot}8237,$$
$$\sqrt{(1-r^2)}=0{\cdot}566881 \text{ when } r=0{\cdot}8238,$$

and a slide-rule calculation is necessary to evaluate the function when $r=0{\cdot}8237463$.

The tables were calculated with a view to their bearing on partial correlation coefficients: they serve equally to determine $\cos\theta$ and $\cos^2\theta$ from $\sin\theta$ by a single reading.

(3) On the two sides of this card are printed the numerical values of sixteen functions, x^2, x^3, $\sqrt{x}$, $\sqrt[3]{x}$, $x^{\frac{3}{2}}$, $1/x$, $\log_{10} x$, $\log_e x$, e^x, e^{-x}, $\sin x$, $\cos x$, $\tan x$, $\sinh x$, $\cosh x$, and $\tanh x$, the intervals for x being 0·1 between 0·0 and 5·0, and 0·5 between 5·0 and 10·0. In tabulating the circular functions, x is measured in radians and not in degrees. Except in special cases two-figure accuracy is retained throughout. This amount of accuracy is sufficient for plotting many elementary graphs for the purpose of which the card is primarily intended. W. E. H. B.

Essai d'optique sur la gradation de la lumière. Par Pierre Bouguer. (Collection "Les Maîtres de la Pensée scientifique.") Pp. xx+130. (Paris: Gauthier-Villars et Cie, 1921.) 3 francs.

PIERRE BOUGUER was born at Croisic in 1698. At an early age he was initiated in mathematics and problems of navigation by his father, who was one of the best hydrographers of his time. When only fifteen years of age he occupied the chair of his father, who had just died, and afterwards distinguished himself by his researches in physics, astronomy, and navigation. He is remembered to-day principally by his work on photometry, and by his expedition to Peru in 1735 to carry out a measurement of a degree of latitude, thus contributing to the solution of the important problem of the figure of the earth. It was during this expedition that he obtained an estimate of the mean density of the earth from pendulum observations in the neighbourhood of Chimborazo. The present essay, in which he laid down the fundamental bases of the science of photometry, is reproduced from the original text of 1729. The author discusses methods of measuring the intensity of light, the manner in which the intensity is changed by reflection or by absorption, and explains how to calculate the diminution in the intensity after the light has passed through various thicknesses of the absorbing medium. His work is distinguished by its clarity and the masterly realisation of the essential points in the problem to be solved.

The Internal Combustion Engine: a Text-book for the Use of Students and Engineers. By H. E. Wimperis. Fourth edition (revised and enlarged). Pp. xvi+320. (London, Bombay and Sydney: Constable and Co., Ltd., 1922.) 12*s.* 6*d.* net.

IT is not surprising that a fourth edition of this valuable work should have been called for within thirteen years after its first publication. As is well known, the progress of the internal combustion engine during the war was very rapid, due largely to aviation. By rearranging some of the older matter, the author has been able to give an account of these advances, including recent experimental work on explosions in closed vessels, and modern fuels and fuel mixtures suitable for use in petrol engines. The chapter on the efficiency of petrol engines has also been brought up-to-date and now includes

some matter referring to the loss of power at altitudes in aero engines. Two methods have been proposed for getting rid of this difficulty, namely, the production of an artificial atmosphere by means of a blower in the carburettor intake, or using an oversize engine, which is kept throttled down at low altitude. In either case, the object is to design an engine which can develop constant power up to a certain height. For altitudes up to 20,000 feet, the over-dimensioned engine appears to be considered the simpler solution.

Mazes and Labyrinths: A General Account of Their History and Developments. By W. H. Matthews. Pp. xviii+254. (London: Longmans, Green and Co., 1922.) 18*s.* net.

MR. MATTHEWS, who does not pretend to be a trained archæologist, tells us that his book originated in a question addressed to him by his little son as he played on the seashore, "Father, who made mazes first of all?" As his bibliography shows, he has studied the literature of the subject, and he has collected much information summarised in a popular way. He begins with the two great labyrinths of antiquity, that at Knossos in Crete, and the second near Lake Moeris in Egypt. In describing these, he depends on the safe guidance of Sir A. Evans and Prof. Flinders Petrie. The former was based on a tradition of the complex of buildings forming the royal palace, the latter was possibly used for sepulchral purposes. Though, as Sir James Frazer suggests, the dancing-places associated with these ancient labyrinths may have been used in some magical way connected with sun worship, it is difficult to connect them with modern mazes, like those at Hampton Court or Hatfield, adjuncts to garden planning, and intended for the amusement of visitors. The best part of the book is the collection from various sources of illustrations of various types of mazes. Many of these have been destroyed in modern times, and this book may serve a useful purpose in directing attention to their interest, and may tend towards the preservation of those which survive to our day.

The Outdoor Boy. Edited by Eric Wood. (The Modern Boy's Library.) Pp. 280. (London: Cassell and Co., Ltd., n.d.) 5*s.* net.

PROBABLY no class of the community takes a greater interest in the education of their sons than the readers of NATURE. While the most suitable form of education will long remain the subject of debate, few will deny the importance of the out-of-doors side, both from the point of view of awakening a love for and an interest in Nature and preparing for the duties of citizenship.

The book before us, one of a series edited by Mr. Eric Wood, is divided between scout-craft and Nature-craft, the idea being to convey to the boy in a clear and simple manner many of those things which he most wishes to know. The scout-craft section appears to us most admirable and should be a mine of information to many a boy who is unable to join an actual scout troop. The Nature-craft section consists of an excellent chapter on bird study and similar chapters packed with information about the insect world. Boys upon whom we have tried the test find it altogether admirable.

A Text-book of Quantitative Chemical Analysis. By Dr. A. C. Cumming and Dr. S. A. Kay. Fourth edition. Pp. xv+432. (London: Gurney and Jackson; Edinburgh: Oliver and Boyd, 1922.) 15*s.* net.

THE first edition of this book was published in 1913, and the appearance of the fourth edition less than ten years later shows that it has been found in practice a most useful guide to students. The present volume should provide a sound course of quantitative analysis for students in universities and technical schools. It is very practical, and gives many hints to students which will save the time of teachers. The reduction method with Devarda's alloy might have been given for the estimation of nitrates, instead of the one with reduced iron, which is less satisfactory. In the description of the Lunge nitrometer no mention is made of the important correction for the solubility of nitric oxide in the acid. The directions for the preparation of cupferron reagent on p. 410 will be found useful, as the price charged for this substance is almost prohibitive.

Group Psychology and the Analysis of the Ego. By Dr. Sigm. Freud. Authorised translation by James Strachey. (The International Psycho-Analytical Library, No. 6.) Pp. v+134. (London: G. Allen and Unwin, Ltd., 1922.) 7*s.* 6*d.* net.

A GOOD and clear translation of Freud's short essay on group psychology is given by Mr. Strachey. The work begins by a brief examination of the views of earlier writers, particularly of Le Bon and M'Dougall. Freud's own method of approach to social psychology is naturally by way of an analysis of the motives of individual behaviour. He treats the group as a collection of persons bound together by some form of love relationship, and to the formation of the group ascribes what to many will appear to be an overweighted importance to the leader. His discussions of the phenomena of "identification," and of the relations of "being in love and hypnosis," are interesting in themselves; but his application of the results of his discussions to the explanation of social behaviour is not convincing.

Elementary Organic Chemistry. By W. H. Barrett. Pp. 256. (Oxford: Clarendon Press; London: Oxford University Press, 1922.) 4*s.* 6*d.* net.

DURING the last two or three years a number of elementary books on organic chemistry have appeared, and it may be doubted whether any purpose is served by further multiplication of the same material treated in the same way. The present volume has no very new features, but it gives a very clear and interesting account of the fundamental facts and theories of organic chemistry suitable for students preparing for scholarships at the universities. It also provides a course suitable for those beginning the subject in the universities, and for medical students. Experiments are included. The section on stereochemistry is particularly good, and a chapter is devoted to general methods of synthesis and analysis. The very moderate price of the book and its undoubted merit should make it popular.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Optical Spectrum of Hafnium.

DURING the progress of the work of Coster and Hevesy on the concentration and isolation of the new element hafnium (atomic number 72), the discovery of which was announced in NATURE of January 20, p. 79, we have examined spectroscopically a large number of their preparations in order to establish the optical spectrum of hafnium, and at the same time to assist in the chemical work on its isolation. In all our exposures we have for the sake of comparison also photographed the spectrum of a specimen of very pure zirconium prepared by Coster and Hevesy from commercial zirconium by removing the hafnium content.

The spectra were photographed with a Hilger quartz spectrograph of largest size, and in our preliminary work we have confined ourselves to the spectral region between 2500-3500 Å.U., which could be exposed in a single setting of the spectrograph. The spectra were produced in an ordinary carbon arc, the salts being placed on the cathode. The lines which are given in the table below as the most prominent hafnium lines in the region mentioned, are all lines which were not visible in an intense spectrum of the purified zirconium, while their intensity increased gradually in the preparations which by X-ray analysis were found to contain hafnium in increasing amounts. In the last specimens prepared by Coster and Hevesy, and estimated to contain about 90 per cent. hafnium, the lines ascribed to hafnium were among the most intense lines in the spectrum. In the table is given the wave-length λ in international Å.U. in air, measured against iron normals, and an estimation of the relative intensity I in the usual scale (strongest lines denoted by 6).

λ.	I.	λ.	I.	λ.	I.	λ.	I.
2559·05	3	2845·75	5	2954·20	5	3181·00	3

We have examined the hafnium preparations for the presence of the lines belonging to the characteristic spectrum ascribed by Urbain (*Comptes rendus*, t. 152, 1911, p. 141) to an element celtium belonging to the family of rare earths, and the discovery of which was announced by him several years ago. By Dauvillier and Urbain (*Comptes rendus*, t. 174, 1922, pp. 1347 and 1349; NATURE, February 17, p. 218) this element was assumed to possess the atomic number 72. Not the slightest trace, however, of any of Urbain's lines appeared on our plates. Although the minerals used as starting-point for the work of Coster and Hevesy contained rare earth elements in considerable amount, the only elements besides hafnium which could be detected spectroscopically in their preparations were zirconium and titanium. It is interesting to notice that some of the most prominent hafnium lines have been present as weak lines in zirconium spectra measured by earlier investigators. Thus Bachem (Diss., Bonn, 1910) states the presence in his zirconium spectrum of the lines marked in the above table with an asterisk, and in several places he states without giving any measurements the presence of weak lines, which probably are identical with other of our hafnium lines.

A fuller account of the hafnium spectrum, with measurements of the wave-lengths of the characteristic lines throughout the region which is obtainable photographically, will appear shortly.

Echinoderm Larvæ and their Bearing on Classification.

THE object of my reply to Prof. MacBride (NATURE, December 16, 1922, p. 806) was not to discuss the classification of Asteroids, but to protest against the character of his unprovoked attack on me. An adequate discussion of the question which group of starfishes is the more primitive, the Phanerozonia or the Spinulosa, requires very much more space than that allotted to a correspondence in NATURE. What I wanted to prove—and, I think, did prove—was the want of foundation in Prof. MacBride's sweeping statement that all admit the Spinulosa to be the more primitive group, tending to represent my view as to this point as perfectly absurd.

Prof. MacBride now states (NATURE, January 13, p. 47) that in my original work I "forgot that the Brachiolaria larva was found in Spinulosa but referred it to Forcipulata only." It is difficult to understand how I could have forgotten this, seeing that I have myself reared the larva of *Asterina pectinifera* and found it to be a Brachiolaria; moreover, in the very place (p. 220) where I arrive at the objectionable conclusion that the Brachiolaria is a specialised, not a primitive larval form, I begin with this statement: "While it would thus appear to be a rule that the larvæ of the Phanerozonia have no Brachiolaria-stage, the facts known of the development of the Spinulosa and the Forcipulata (Cryptozonia) seem to indicate that their larvæ are characteristic through having a Brachiolaria-stage." Is it too much to ask that, before thus criticising my work and accusing me of omissions, of which I am not guilty, or of absurd opinions (*e.g.* of regarding the metamorphosis of Echinoderms as metagenesis), which I have never set forth, Prof. MacBride would, at least, read the questionable paragraphs in that work? I have never stated that the case of the regenerating larva, *Ophiopluteus opulentus*, even if it undergoes complete metamorphosis a second time, must alter our views as to the signification of Echinoderm larvæ in general, only that this would represent a quite exceptional and unique case of metagenesis among Echinoderms.

Regarding the classification of Asteroids I will say only that the physiological and anatomical reasons given by Prof. MacBride for regarding the Astropectinids "as Asteroids secondarily modified for a life on sand" would scarcely be accepted as a sound basis for classification by any modern specialist on Asteroids, those "students of the external features of preserved specimens only," as Prof. MacBride rather contemptuously characterises them. May I only direct Prof. MacBride's attention to the fact that

numerous Astropectinids live exclusively on a muddy bottom, and also that numerous Spinulosa and Forcipulata live on a sandy or muddy bottom.

Prof. MacBride states that my appeal to Dr. Bather's reply is quite mistaken, because I forget that "what Dr. Bather objected to was my [Prof. MacBride's] fathering of Dr. Mortensen's views on him." May I only quote the following sentence from Dr. Bather's reply: "It is not for me to break any lances in defence of Dr. Mortensen, but if Prof. MacBride is acquainted with Dr. Mortensen's 'Studies in the Development of Crinoids' . . . I am rather astonished that he should so belittle our Danish colleague's work on those lines." If this sentence is meant by Dr. Bather to express his substantial agreement with Prof. MacBride in their views on Echinoderms or to repudiate Prof. MacBride's fathering of my views on him, I am very sorry that I shall have to moderate very considerably the admiration which I have always had for his lucid way of expressing his opinions.

To Prof. Gemmill's remarks (NATURE, January 13, p. 47) I must reply very decidedly that I am not narrowing down the Phanerozonia to include only the family Astropectinidæ. The families Luidiidæ, Archasteridæ, and Goniasteridæ, at least, are likewise typical Phanerozonia. On the other hand, the position of the Asterinidæ and the Gymnasteridæ is just one of the weak points in the classification of Asteroids, and the latter can by no means be said to be "frankly Phanerozonate."

The conclusion that, since the larvæ of the two families, Astropectinidæ and Luidiidæ (not of the Astropectinidæ alone as Prof. Gemmill states, by inadvertence, of course), regarded (by most specialists on Asteroids) as the more primitive forms, have no sucking disc, the existence of such a disc in the larvæ of those groups regarded (by most specialists on Asteroids) as more specialised types, is a secondary adaption, may, possibly, not be "inevitable"; but, in any case, this conclusion is not illogical or absurd. I have no direct interest in maintaining the Brachiolaria to be a secondarily specialised larval type. If conclusive proof is given that the Brachiolaria is the primitive, the Astropectinid-larva the specialised form, I shall not hesitate to drop my present view. But I must maintain that this view is not unjustified by the facts so far known.

I am sure Prof. Gemmill will agree with me as to the desirability of researches on the development and metamorphosis (and, not least, the postembryonal development) of many more forms than those few, which have been studied up to now. Not even the development and metamorphosis of Asteropecten has been studied by means of modern methods, the researches of Joh. Müller and Metchnikoff still remaining the only base of our knowledge of this subject. I hope very sincerely that Prof. Gemmill will extend his admirable studies to this and many other Asteroids, as I also hope that both he and Prof. MacBride will agree that my efforts to widen our knowledge of the development of Echinoderms are not entirely without value, and that the views expressed in my work, however much they may disagree in them, are not entirely without reasonable foundation.

TH. MORTENSEN.

Zoological Museum, Copenhagen,
January 22.

I SHALL summarise the points at issue between Dr. Mortensen and myself as briefly as possible.

He complains that I made an "unprovoked personal attack" on him. Nothing was further from my intentions. The so-called attack was a criticism of certain views attributed to Dr. Mortensen by Dr. Bather in a review of one of Dr. Mortensen's recent works in NATURE. Dr. Bather seemed to think that Dr. Mortensen believed that after all the development of Echinoderms might be an alternation of generations as Johannes Müller originally suggested. As Dr. Mortensen has unreservedly repudiated this view there is nothing more to be said on this point.

But Dr. Mortensen did say that the fixed stage in the development of Asteroids (discovered by me in 1893) was of secondary character, because it was absent in two families (Astropectinidæ and Luidiidæ) classed together as Paxillosa. I had a perfect right to comment severely on statements such as these, because (1) the fixed stage is found in the most widely diverse families belonging to two of the great primary divisions of Asteroidea. (2) The fixed stage regarded as an ancestral reminiscence, enables us to understand how and why the ancestors of Asteroidea passed from the stage of free-swimming bilaterally symmetrical animals to the stage of radially symmetrical forms creeping over the bottom. (3) If Dr. Mortensen had known what he as a specialist in Echinoderms might reasonably be expected to know, namely, what has been determined as to the physiology and habits of Luidia and Astropecten, he could never have regarded them as primitive, but would have recognised them as what they are, the most specialised of all Asteroidea.

It is not a question of the ground on which particular starfish can be dredged up. Every marine biologist knows that sporadic individuals of rock and gravel-inhabiting species can be dredged on sand or mud. The dredge, indeed, gives no precise information as to the habitat of a species, for the bottom is usually "patchy." But Luidia and Astropecten *when observed in life* are found to be *burrowing species*, which when at rest are almost completely buried in the sand or mud in which they live like many Ophiuroids, and the structure of the arms is modified in relation to such habits. A fixed stage in the ontogeny of such forms would be an impossibility, for in such an environment the larva would find nothing to which it could attach itself. By a happy coincidence I received a few days ago Part V. of W. K. Spencer's "Palæozoic Asterozoa." In this work I read "The existence of large marginals throws no light on the affinity of extinct species, but it does throw light on the shape of the arm" (*i.e.* it is adaptive). When the arm is flat and the dorsal skeleton reduced to a flexible membrane the borders of the arms must be strengthened.

Dr. Mortensen accused me of referring contemptuously to certain specialist students of external features only. I am afraid I must plead guilty on this count. I have spent weary time in going through the ponderous works of Sladen and Ludwig, and so far as any attempt to correlate structure with function is concerned, these authors might just as well have been describing postage stamps as Asteroidea. The distinction between Phanerozonia and Cryptozonia was made by Sladen. The Phanerozonia were stated by him to be the original and primitive group (*a*) because fossil starfish were all phanerozonate, (*b*) because cryptozonate forms when young are phanerozonate.

I have never been able to find the evidence on which (*b*) is based. I have often seen young imagines of Asterias and Asterina, but there is certainly nothing "phanerozonate" in their appearance. Statement (*a*) is absolutely inaccurate. If Dr. Mortensen is open to conviction on this point let him study W. K. Spencer's monograph, where he will find every fossil form from Palæozoic strata carefully described, and further, an attempt made to correlate its structure with its probable habits. He will learn that Cryptozonia are just as old as Phanerozonia, and that the

oldest starfish of all are neither Cryptozonate nor Phanerozonate and have no plates corresponding to the marginals of Astropecten at all.

Lastly, as to the accusation that I belittled Dr. Mortensen's work. I have no wish to depreciate his work, but with the exception of the treatise on the Crinoids (Comatulidæ), which is irrelevant to the point at issue, it is not what I regard as embryology at all. By that term I understand the attempt to follow through the development of the organs of the adult from their beginnings in the embryo or larva with a view of obtaining light on the ancestry of species. Dr. Mortensen's researches on Echinoderm larvæ have been purely classificatory, and he has done valuable work in determining which larval forms belong to certain adults. His recent work on Comatulidæ, it is true, is embryological: he has confirmed the results of Bury and extended them to other species; but he dismisses the conclusions of other embryologists without sufficient consideration of facts.

Medical Education.

I AM sorry Prof. Dakin (NATURE, February 3, p. 151) should think my letter (NATURE, January 13, p. 50) merely an attempt to open another discussion on evolution. I do not know how I could have expressed myself more clearly. Manifestly, a knowledge of such things as the anatomy of frogs and dog-fish cannot persist in the minds of medical students or be useful to them intellectually or professionally unless linked with other studies. They can be so linked only through truths about development, variation, heredity, and evolution. But here the naturalist is in conflict with the physiologists, psychologists, pathologists, and medical men into whose hands the students pass and whose opinions, abundantly supported by evidence, they always adopt.

It is one thing to demonstrate that evolution has occurred, and for this none are better qualified than naturalists. But evolution is not disputed by medical men, though, owing to the biology they learn, few give it a thought. It is quite another thing to demonstrate the method of evolution. Here, to say the least, naturalists are not in a position to ignore evidence derived from other sciences. For example, they have very diverse opinions about fluctuations. But did ever a naturalist see a fluctuation in a living being existing under natural conditions, other than man (*e.g.* a sparrow or house-fly, the most familiar of all)? If he did, was he able to follow that being throughout its career and test the influence of that fluctuation on its life? If he did, was he able to note the effect on offspring and descendants?

Very obviously our whole *immediate* knowledge of fluctuations, natural selection, and the method of evolution is derived from human beings, among whom alone we are able to observe with that sufficiency and minuteness which extreme familiarity confers. Thus every man (not only Prof. Dakin's superman) knows that powers of resisting the carnivorous bacillus of tuberculosis occur in all shades between wide extremes (therefore they are fluctuations); that they tend to run in families (therefore they are inheritable); that the less resistant tend to perish and the more resistant to survive (therefore there is natural selection); that every race is resistant n proportion to the length and severity of its sufferings (therefore natural selection is the antecedent of evolution); and that what is true of tuberculosis is true also of every lethal and prevalent disease (therefore the instances are in thousands and include all the world and all humanity—indeed every case in which we are able to observe closely).

Naturalists, unable to observe either fluctuations or natural selection among plants and lower animals, must get their ideas about the method of evolution either from observations on man or else through mere guessing. Apparently they prefer not only to guess but to claim scientific status for their guesses. After all, man is an animal. I do not know why he should be thought unworthy of study.

What does Prof. Dakin mean by "it is highly desirable that first-year medicals, raw youths from school, should make their first acquaintance with the animal world through less expensive material than human bodies"? Expensive in what—money or time? Does Prof. Dakin suppose that raw youths dissect fewer humans because they dissect more frogs?

I gather that he disapproves of attempts by me to discuss evolution, "for his letter indicates a very imperfect acquaintance with biologists and their work." I think by biologists he means zoologists and botanists. But, if I be incapable, why not end the nuisance by indicating my errors. A jury always grows suspicious when not the evidence, but only the opposing attorney is attacked. There has been much of this hinting at my ignorance—doubtless with reason, if not with proof. Nevertheless, I know some elementary facts which, it seems, are outside the range of the average naturalist, *e.g.*, that events do not happen (characters do not develop) without antecedents (nature) and exciting causes (nurture); that living beings are bundles of adaptations; that the multicellular organism springs from a germ in which are none of the characters it afterwards develops, and therefore, inherits nothing but its nature (the sum of its potentialities for development), and develops nothing except in response to nurture; that our powers of observation are proportionate to our familiarity with the objects of study; that whenever we are able to observe sufficiently closely we always find natural selection in full swing; that the variations selected by Nature are always fluctuations; that the result is always adaptive evolution; that man, unlike Nature, frequently selects mutations; that therein lies the difference between natural and artificial selection; and so on.

On these elementary facts I have founded some equally elementary questions. Why are some characters supposed to be more innate, or acquired, or inheritable than others? What precisely was the great Lamarckian controversy about? Was it founded on anything but a play on words? Why is the word inherit used with two directly contrary meanings? What is meant by the statement that "Nature is five perhaps ten times stronger than nurture," and what by the statement that "mutations, but not fluctuations, have their representatives in the germplasm"? Why, in the face of enormously massive evidence, is it supposed that there is no natural selection, or that natural selection is merely a preserver, not a creator, of adaptations? Why in the face of equally massive evidence is it maintained that the inheritance, not merely the reproduction, of mutations is independent? And so on. I notice that the erudite people who are so ready to proclaim my ignorance are not equally ready to face these facts and answer these questions. Nevertheless, both facts and questions, however elementary, are fundamental. Unless they be met, posterity will regard a page of Darwin, who always met his difficulties with candour and without arrogance, of more value than all

the thousand publications of those who bark at the dead lion.

As Prof. Dakin has been good enough to suggest that I am ignorant, may I supply him with proof and the readers of NATURE with a test? I do not know what naturalists (the biologists of Prof. Dakin) mean by their key-words "innate," "acquired," and "inherited" when applied to characters. Does Prof. Dakin know? Will he tell us?

G. ARCHDALL REID.

Southsea, February 19.

A Relativity-predicted Mechanical Effect in the Electromagnetic Field.

THE present writer would certainly starve if his bread depended on supplying a certain experimental verification here asked for. It should, however, be mere Boys' play to those who measure the gravitational constant with a little pile of sovereigns and a quartz fibre, or who photograph the wake of a flying bullet. The mathematical argument leading to the prediction indicated below is sent to England by the mail carrying this letter, for publication, but I cannot say where and when it will appear.

A body, say a crystal, at rest in an electromagnetic field should experience a force per unit volume, in Maxwell's notation and in E.M. units, equal in magnitude and direction to

$$\mathrm{V}\mathbf{K}\mathbf{B} - \mathbf{E}\mathrm{S}\nabla\mathbf{D} + \frac{d}{dt}\mathrm{V}(\mathbf{D}\mathbf{B} - \mathbf{E}\mathbf{H}/4\pi c^2),$$

where **K** is conduction current and c the velocity of light *in vacuo*. It is possible that the third term has been given before, but I have not seen it anywhere. The verification here asked for is that of the existence of this term. VEH is in the direction of a light ray and VDB is normal to the corresponding front. In an isotropic transparent body, $\mathrm{VDB} = k^2(\mathrm{VEH}/4\pi c^2)$, where k is the index of refraction.

Unfortunately, $4\pi c^2$ is about $10^{22} \times 1{\cdot}131$, but my son, Dr. A. L. M'Aulay, tells me that the magnitude of VEH may readily be made equal to 10^{16}, so that the effect may be detectable.

The term indicates that when a wave-train traverses a point the matter at the point is always urged along the ray *towards* the nearest wave-crest or wave-trough, and normal to the front *from* the nearest crest or trough. Can any reader suggest a plausible physical reason why this should occur?

I may remark that Maxwell's expression for the force per unit volume is

$$\mathrm{V}(\mathbf{K} + d\mathbf{D}/dt)\mathbf{B} - \mathbf{E}\mathrm{S}\nabla\mathbf{D},$$

and that probably most relativists would drop the $d\mathbf{D}/dt$ from this expression. Let the physicist tell us which, if any, of the three expressions is verified experimentally.

ALEX. M'AULAY.

University of Tasmania, November 28, 1922.

The Measurement of the Rates of Oxidation and Reduction of Hæmoglobin.

WE have recently been engaged on the determination of the velocities of the chemical reactions of hæmoglobin. These are of interest both to the physiologist because of the important part played by this pigment in respiration, and also to the physical chemist because this pigment is an almost unique example of a large complex protein molecule which combines with gases in a simple chemical manner. Some of the results that we have obtained and the methods we have used may therefore be of interest to readers of NATURE.

In order to measure the rate of reduction two solutions were prepared: (*a*) a 1·5 per cent. solution of whole blood in tap water, (*b*) a solution of sodium hyposulphite ($Na_2S_2O_4$) in tap water which was rendered neutral to brom-thymol-blue by the addition of sodium carbonate solution. These two solutions were by suitable means forced under a pressure of, roughly, 500 mm. of mercury into the mixing chamber of the measuring apparatus through conical jets of small bore, so that the two solutions underwent vortex motion at a high rate of speed. Preliminary tests of the measuring apparatus, using as fluids a sodium hydroxide solution containing phenol phthalein and a rather stronger solution of acid, showed that mixing and chemical combination were complete with one measuring apparatus in less than 0·0055 sec., and with another apparatus in less than 0·0005 sec. The mixed blood solution and reducing agent passed from the mixing chamber of the apparatus in use down a glass tube with known velocity, being examined at different positions by means of the reversion spectroscope, by which we could ascertain the ratios of those amounts of hæmoglobin still combined with oxygen and those in the reduced state.

We thus obtained the concentration of oxyhæmoglobin (O_2Hb) at a series of instants, the intervals between which could be readily obtained from the rate of linear flow of the solution down the tube, and the positions of the points examined by the spectroscope.

Experiments on the rate of reduction of oxyhæmoglobin (O_2Hb) by the reducing agent ($Na_2S_2O_4$) have shown that with increase of concentration of the latter the rate of reduction increases to a maximum, beyond which it cannot be raised by a further increase. This we take to mean that the process consists of two stages:

(1) Reduction of oxyhæmoglobin, *i.e.*

$$O_2Hb \rightarrow O_2 + Hb.$$

(2) Removal of O_2 (liberated from O_2Hb) by combination with the reducing agent.

As the concentration of the reducing agent is increased, the free oxygen formed from O_2Hb by stage 1 is removed more quickly, until a concentration is reached at which the "free" oxygen is removed so quickly that the reaction $O_2Hb \rightarrow O_2 + Hb$ is not appreciably opposed by the reverse reaction $O_2 + Hb \rightarrow O_2Hb$. Further increase in concentration of the reducing agent cannot therefore further accelerate the velocity of the reduction of the O_2Hb, the latter being now solely determined by the velocity of the reaction $O_2Hb \rightarrow O_2 + Hb$. We have other evidence in support of this view, which we hope to present at length elsewhere. The time taken for complete reduction of O_2Hb when the concentration of $Na_2S_2O_4$ was sufficient to secure the "maximum" rate of reduction was about 0·5 sec. at 12° C. This rate of reduction is such as to be a factor of importance in considering the conditions which determine the rate of uptake of oxygen by organs within the body. We found further that the logarithm of the concentration of O_2Hb when plotted against time gave a straight line relationship, as should indeed be the case if the reduction of O_2Hb is a monomolecular process.

The measurements of the velocity of oxidation of hæmoglobin required the preparation of large quantities of reduced hæmoglobin solution. This was obtained by spraying a solution of blood in tap water heated to 50° C. into a large vacuous container, thus causing the gases combined with the hæmoglobin to be liberated. This reduced blood solution was mixed with water containing dissolved oxygen by

forcing both fluids into the mixing chamber of one of the observing apparatus described above. It was found that the combination was a very rapid one, the reaction being complete in one hundredth part of a second at 10° C. At body temperature it is probable that the velocity would be even higher. This gives some idea of the intense rapidity with which oxygen entering the blood, as the latter passes through the lungs, becomes chemically combined with hæmoglobin. It seems to us possible that similar methods might be useful for determining the velocity of other rapid chemical reactions.

Stages of Golgi Bodies in Protozoa.

IN the *Anatomischer Anzeiger* (47 Band, 1914) Jan Hirschler, in his paper "Ueber Plasmastrukturen in den Tunicaten-, Spongien-, und Protozoenzellen," gives a description of the trophozoite of *Monocystis ascidiæ*, in which he figures Golgi bodies. This has never hitherto been confirmed, nor are any other stages known.

For some time we have been carrying out work on an Adelea, and after considerable difficulty succeeded in getting excellent preparations of the Golgi apparatus in many stages of the life cycle. In the accompanying illustration (Fig. 1) is the young

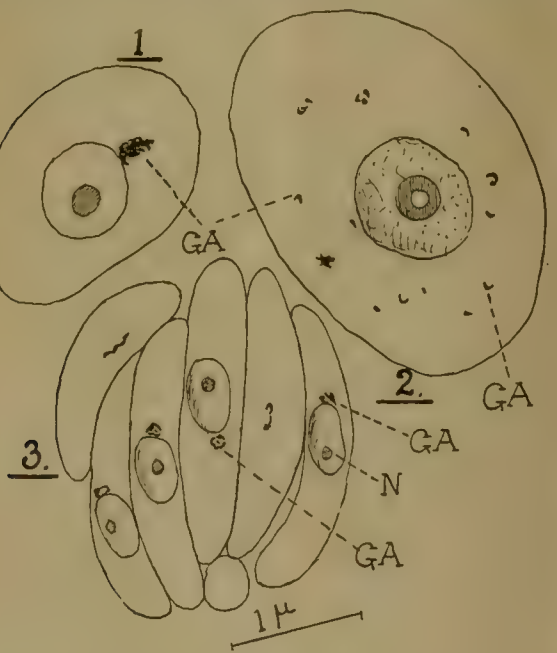

FIG. 1.

trophozoite showing an excentric and juxta-nuclear apparatus (GA); 2, the older trophozoite has a scattered apparatus, and in the "corps en barillet" stage in 3 the apparatus in each cell is again juxta-nuclear and excentric. The work is still proceeding in several species, and this is merely a preliminary announcement.

Selective Interruption of Molecular Oscillation.

MR. FAIRBOURNE (NATURE, February 3, p. 149) has reopened a subject which I believed was certainly closed; but since the fallacy is practically the same as before, though a little less easy to detect, I feel that I cannot then have been sufficiently clear for him.

None of Mr. Fairbourne's arguments has yet disposed of the validity of the ordinary treatment to be found in any text-book on the kinetic theory; for the elementary kinetic treatment of gaseous pressure is independent of the diameters of the gas-molecules, and would be perfectly valid if they were, as for the first approximation they are assumed to be, particles of a finite mass but zero radius; in this case, however, the mean free path would be infinite at every pressure, so that Mr. Fairbourne has introduced no new factor by confining himself to the case of long free paths.

This being so, it is not to be expected that space can be found in these columns for a disproof of whatever inadequate alternative to the accepted methods of analysis may be brought up; but I suggest that in this particular case he has not proved that he has satisfied a condition which he admits is vital, namely, that the numbers of molecules crossing XY and AD *in unit time* must be shown to be not proportional to their lengths. Many of the "superfluous" molecules which ultimately cross XY spend first a long time in the cone; there is nothing in his treatment which prevents such molecules being counted a very large number of times, since all points on their long paths may equally be taken as centres of small spheres O. Mr. Fairbourne's treatment is inconvenient; but it is obvious, since it does not discount the classical method, that, if carried out correctly, even it would have given the classical result.

I have always maintained that the length of the mean free path is irrelevant; I observe that he now admits this ("Subsequent intermolecular collision in the cone cannot destroy the excessive downward bias," etc.). The inevitable conclusion, as I pointed out last July, is that the pressure is without any influence except on the *magnitude* of the effect. It being granted that the molecules do not interfere with one another in any relevant way, the effect must be directly proportional to their number, *i.e.* to the total pressure. At atmospheric pressure, therefore, perpetual motion should be an accepted phenomenon even if the effect were measurable only with ambiguity at the pressures used by Mr. Fairbourne.

A Biochemical Discovery of the Ancient Babylonians.

AT a lecture given recently in Cambridge by Prof. Okey my attention was directed to a passage written by Galileo in 1623 in which this pioneer of scientific method attacks the doctrines of the classical philosophers with his usual irony and vehemence. I refer to a section of his "Il Saggiatore," in which Galileo replies to his contemporary Sarsi, who had quoted Suida to the effect that the Babylonians used to cook eggs in an emergency and when no fire was available, by rapidly whirling them in slings. ("Babylonii iniecta in fundas ova in orbem circumagentes, rudis et venatorii victus non ignari, sed iis rationibus quas solitudo postulat exercitati 'etiam crudum

ovum impetu illo coxerunt.' " Suida, Lessicografo. Bizant., x.)

Galileo makes the following caustic comments: " Se il Sarsi vuole che io creda a Suida, che i Babilonii cocesser l' uova col girarle velocemente nella fionda, io lo crederò; ma dirò bene, la cagione di tale effetto esser lontanissima da quella che gli viene attribuita, e per trovar la vera io discorrerò cosi: Se a noi non succede un effetto che ad altri altra volta a riuscito è necessario che noi nel nostro operare manchiame di quello che fu causa della riuscita di esso effetto, e che, non mancando a noi altro che una cosa sola, questa sola causa sia la vera causa. Ora, a noi non mancano uova, nè fionde, nè uomini robusti che le girino; e pur non si cuocono; anzi, se fusser calde, si raffreddano più presto; e perchè non ci manca altro che l' esser di Babilonia, adunque l' esser Babiloni è causa dell' indurirsi l' uova e non l' attrizion dell' aria: che è quelo ch' io volevo provare." (If Sarsi *commands* me to believe on the authority of Suida that the Babylonians used to cook eggs by swiftly swinging them in slings—I will. But I will certainly say that the cause of such results is far from that which he attributes; and in order to discover the true cause I will reason in the following way: If we do not succeed in obtaining a result which was successfully obtained at another time, some one factor at least must be lacking which is necessary for the successful production of the result. Now, we have no lack of eggs, nor slings, nor strong men to swing them, *and yet they do not cook; on the contrary*, if already warmed the swinging would cool them more quickly. Since the only factor that is lacking is that we are not Babylonians, therefore the fact of being a Babylonian is the cause of the eggs solidifying, and not the friction of the air: and this is what I set out to prove.) (Galilei, Opere, vi. Also in "Frammenti e Lettere" (1917), p. 66).

If Galileo had actually put his experiment to the test he might have written otherwise. Within the last few years it has been "discovered" that egg white under mechanical strain such as *vigorous shaking* or very high hydrostatic pressure undergoes coagulation (*vide* Robertson, "Physical Chemistry of the Proteins," 1918). In a paper to be published shortly in the Proc. Roy. Soc. (read at the meeting of February 15), I show that chemical changes which occur on heat-coagulation also occur on coagulating an egg by mechanical means.

The myths and anecdotes of the ancients are almost invariably built on some foundation of fact; and it seems highly probable that the Babylonians were aware that eggs could be coagulated by vigorous movement (such as swinging in slings). If this be so, the phenomenon of mechanical coagulation proves to be another example of a former observation rediscovered—in this case after the lapse of thousands of years! LESLIE J. HARRIS.

Use of Yeast Extracts in Diabetes.

WE have recently shown (*Journ. of Physiol.* 57, p. 100, 1922) that there is present in the blood of normal persons a sugar of a reactive nature, which gives the same osazone as glucose, but has a lower rotatory power. In the blood of persons suffering from severe diabetes mellitus, this sugar is not present in amounts capable of detection. In conjunction with Dr. Devereux-Forrest, we have found that, after administration of insulin to diabetic persons, whereas the quantity of sugar in the blood is decreased, the amount of normal blood sugar is increased.

We have also shown (Proc. Physiol. Soc., December 16, 1922) that extracts of pancreas and liver together alter the rotatory powers of glucose and fructose *in vitro*. It was suggested that the absence or inactivation of either the pancreatic or liver factor was the cause of diabetes. Since the pancreatic and liver factors were markedly accelerated by the addition of phosphates, it seemed possible that one constituent of the pancreatic factor might be a sugar-phosphoric acid complex. As an essential step in the metabolism of sugar by yeast is held to be the formation of hexose-phosphoric acids, it seemed possible that an extract of yeast might take the place of the pancreatic factor.

We have obtained a solid preparation from yeast which would appear to have similar properties and effects.

When a solution of this substance is injected into rabbits, a very definite lowering of the blood sugar occurs, in every way comparable to that which we have found after injections of insulin. Rats when injected die in convulsions similar to those caused by insulin.

Some properties of insulin and of this extract of yeast are very similar. Both contain organic phosphorus and carbohydrate. Seliwanoff's reaction is positive in each case after hydrolysis.

We are at present engaged in a further investigation of these extracts. L. B. WINTER.

Meteorological Nomenclature and Physical Measurements.

IN reply to Sir Napier Shaw's kindly rejoinder in NATURE of February 17, p. 218, to my meditations on the progress of meteorology, I prefer to his simile of a boat-race that of boats striving to tow the not yet quite ship-shape bulk of meteorological research forward on its destined course. Although Sir Napier Shaw's was the best equipped of the boats, in which he was able to experiment with new modes of propulsion, I am sure he recognises that I was pulling with all my strength, if independently, at least in the same direction as himself. That I pulled in grim earnest with the result of long disablement accounts for my present position (which strikes me as more desolate than dignified) on the shelf, from which I see the now graceful lines of the new meteorology moving ahead with Sir Napier's new engines installed, and though almost out of hearing I listen to their beat in order to form an opinion as to how they act. I should be sorry indeed if anything I said were to retard or discourage any one on board that craft or cast a shadow on the laurels with which Sir Napier Shaw has been crowned by the scientific world to the joy and pride of every British meteorologist.

Dropping metaphor, there is surely large room for helpful difference of opinion as to terminology and the relative value of facts and formulæ. I do not dislike the metric system in spite of its occasional awkwardnesses, nor would I hesitate to embrace the millibar if it seemed to me to be making for unity instead of adding a new ramification to diversity. In the works I was reviewing I failed to see the signs of the coming of the millenium of the millibar; but if it is on its way, "come it will for a' that."

HUGH ROBERT MILL.

The Origin or Basis of Wireless Communication.[1]

By Sir OLIVER LODGE, F.R.S.

FINSBURY Technical College has done splendid work throughout its short history. It fills a distinct niche, it supplies a felt want in the education of the Central metropolis, and I hope that any idea of closing it has now subsided. It has had, moreover, a brilliant array of teachers, men who appeared specially adapted to serve the needs of its special kind of students. I will here only mention three contemporaries who worked together after 1885, when the initial start had been made, and the early traditions settled, by Ayrton and Perry. Silvanus Thompson became principal in 1885, and had as his colleagues John Perry and Raphael Meldola. John Perry was remarkable as a teacher, and did his best to cultivate a wider interest in the rather narrow technically trained students who came under his paternal supervision, encouraging them to read novels, to take an interest in literature, and—even in mathematics—to take a broader outlook than most teachers thought it worth while to cultivate. As for Silvanus Thompson, the breadth of his outlook and width of his interests are almost proverbial. He represented a rare combination of scientific aptitude and high artistic faculty, together with a fondness for literary study among archives, and he became in the eyes of all his contemporaries—including Lord Kelvin and Lord Rayleigh—a recognised historian of science. He had a keen love of the past and of discoveries in their nascent stages. Old documents and records were of real interest to him: and he used to do his best to dig out of obscurity some of the pioneers and early workers towards developments which afterwards became famous.

Early pioneering work is too often overlooked and forgotten in the rush of a brilliant new generation, and amid the interest of fresh and surprising developments. The early stages of any discovery have, however, an interest and fascination of their own; and teachers would do well to immerse themselves in the atmosphere of those earlier times, in order to realise more clearly the difficulties which had to be overcome, and by what steps the new knowledge had to be dovetailed in with the old. Moreover, for beginners, the nascent stages of a discovery are sometimes more easily assimilated than the finished product. Beginners need not, indeed, be led through all the controversies which naturally accompany the introduction of anything new; but some familiarity with those controversies and discussions on the part of the teacher is desirable, if he is to apprehend the students' probable difficulties. For though he does not himself feel them now, the human race did feel them at the new fact's first introduction; and the individual is liable to recapitulate, or repeat quickly, the experience of the race.

A large number of people now interested in the most modern developments of wireless have but little idea—perhaps none at all—of the early work, in apparently diverse directions, which preceded and made such developments possible. Even those who are high authorities in wireless telegraphy, and know nearly all that can be known about it—like the distinguished dean of this college, Dr. Eccles—can scarcely know the early stages quite as well as Silvanus Thompson and I knew them; no one, indeed, can afterwards feel in touch with the history so closely as those who have lived through the period covered by it. Only those who have survived the puzzled and preliminary stages of a discovery can appreciate fully the contrast with subsequent enlightenment. It may suffice to say that the term "inductance" or "self-induction," which we now use so glibly, did not at first exist; and that so late as 1888 Sir William Preece still spoke of it as "a bug-a-boo": whereas it is the absolute essential to tuning, and even to electric oscillation. Faraday was the first to direct attention to it, under the name "electrotonic state;" and he treated it experimentally with his usual skill. Lord Kelvin, who first introduced it as a mathematical coefficient, without any explanation, called it "electrodynamic capacity." The name self-induction was given to it by Maxwell, though it was long before it was understood or utilised, and the name "inductance" is a nomenclature of Heaviside.[2]

I wish in this lecture to say practically nothing about anything to do with wireless later than 1896. What I have to deal with is the early pioneering work apart from practical developments. Let me here say at once, to avoid misunderstanding, that without the energy, ability, and enterprise of Signor Marconi, what is now called wireless would not have been established commercially, would not have covered the earth with its radio stations, and would not have taken the hold it has upon the public imagination. Before 1896 the public knew nothing of its possibilities: and for some time after 1896, in spite of the eloquence of Sir William Preece and the demonstrations by Signor Marconi, the public thought it mysterious and almost incredible; and still knew nothing about the early stages. Indeed, I scarcely suppose that Signor Marconi himself really knew very much about them. He had plenty to do with the present; he felt that the future was in his hands; and he could afford to overlook the past.

It may be doubted whether the younger generation, who are so enthusiastically utilising, and perhaps improving, the latest inventions, will care much about the past either. Incidentally, however, I want to say two things to those who are occupied with the subject to-day. First, do not hesitate to speak and think of the *ether of space*, as the continuous reality which connects us all up, and which welds not only us but all the planets into a coherent system. Do not be misled by any misapprehensions of the theory of Relativity into supposing that that theory dispenses with the ether, merely because it succeeds in ignoring it. You can ignore a thing without putting it out of existence: and the leaders in that theory are well aware that for anything like a physical explanation of light or electricity or magnetism or cohesion or gravitation, the ether is indispensable. The ether has all these functions, and many more. We are utilising it every day of our

[1] From the first Silvanus P. Thompson memorial lecture delivered at Finsbury Technical College on February 1.

[2] Silvanus Thompson wrote a pamphlet on the early history of wireless, in connexion with a successful application before Lord Parker for the extension of my fundamental tuning patent of 1897. This pamphlet has never been published, but it ought to be. I had not time to quote from it.

lives; and it would be ungrateful, as well as benighted, if we failed to render due homage to its omnipresent reality and highly efficient properties. It lies at the origin of all electrical developments, and forms the basis for this new and broadcast method of communication.

That is one thing: the second is to congratulate all those whose wonderful and rapid advances have rendered possible the astonishing feat of, in any sense and by whatever means, carrying the human voice across the Atlantic. When Signor Marconi succeeded in sending the letter "s" by Morse signals from Cornwall or Ireland to Newfoundland, it constituted an epoch in human history, on its physical side, and was itself an astonishing and remarkable feat. The present achievement of changing over from Morse signals to ordinary speech, made possible by the valves of Prof. Fleming and Dr. Lee de Forest and others, is a natural though still surprising outcome and development of long-distance transmission, and must lead to further advances, of which at present we can probably form but a very imperfect conception.

Well now, I must go back to very early times. In or about the year 1875 Mr. Edison observed something, which at that time could by no means be understood, about the possibility of drawing sparks from insulated objects in the neighbourhood of an electrical discharge. He did not pursue the matter, for the time was not ripe; but he called it "Etheric Force"—a name which rather perhaps set our teeth on edge;—and we none of us thought it of much importance. Silvanus Thompson, however, took up the matter in a half-hearted sort of way, and gave a demonstration to the Physical Society of London in, I believe, June 1876—a paper which I have had a little difficulty in finding in the Proceedings of that Society. Nothing much came of it, however, though his argument tended to show that the sparks could be accounted for on known principles. The value of this is merely that it must have rendered Thompson susceptible to methods of detecting real electric waves, when they were discovered later.

It was found afterwards that Joseph Henry, at the Smithsonian Institution in Washington, had observed something of the same kind so early as 1842. He seems to have had an intuition of the possible importance and far-reaching consequences of his observation, for he speaks as follows (I quote from a passage cited in my "Modern Views of Electricity," an appended lecture "On the Discharge of a Leyden Jar"[1]):—

> "It would appear that a single spark is sufficient to disturb perceptibly the electricity of space throughout at least a cube of 400,000 feet of capacity, and . . . it may be further inferred that the diffusion of motion in this case is almost comparable with that of a spark from flint and steel in the case of light."

That is to say, so early as 1842 Joseph Henry had the genius to surmise that there was some similarity between the etherial disturbance caused by the discharge of a conductor and the light emitted from an ordinary high temperature source.

In the light of our modern knowledge, and Clerk Maxwell's theory, we now know that the similarity is very near akin to identity. Both sources emit ether waves, though prodigiously differing in length.

Subsequent to these early stray observations, a suggestive semi-private observation, of a partially similar kind, was made by that singular genius and brilliant experimenter, David Hughes, the inventor of the microphone or telephonic transmitter, and of the Hughes printing telegraph still used in France. He was a man who "thought with his fingers," and worked with the simplest home-made apparatus—made of match-boxes and bits of wood and metal, stuck together with cobbler's wax and sealing-wax. Such a man, constantly working, is sure to come across phenomena inexplicable by orthodox science. As a matter of fact, Hughes unknowingly was very nearly on the trail of what was afterwards discovered, in a much more enlightened manner, by Hertz. Hughes, too, got sparks in the course of his experiments, but he also got something very like coherer action by means of his microphone detectors. They enabled him to get actual galvanometer deflexions—such as Hertz never got.

I cannot at the moment fix the date, but it was early in the 'eighties and before either Hertz or me. Hughes was a telegraphist, and though he would never have worked out the subject mathematically as Hertz did, and would not have been interested in matters of theory, he might well have stumbled, even at that early date, on something like a rudimentary system of wireless signalling, had he been encouraged. But he was not encouraged. He showed his results to that great and splendid mathematical physicist, Sir George Stokes; and Stokes, alas, turned them down, considering that they were explicable either by leakage or some other known kind of fact.

That is the danger of too great knowledge; it looks askance at anything lying beyond or beneath its extensive scope; whereas an experimenter operating at first hand on Nature may quite well occasionally stumble on a fact which lies outside the purview of contemporary science, and which accordingly neither he nor any one else at the time understands. Crookes himself had a similar experience. In his pertinacious and systematic way he explored many unfamiliar and untrodden regions; and he also invited the attention of Stokes to a simple and easily investigated case of abnormal movement; Stokes, however, perceiving that such motion was physically impossible, declined to take any interest in it or even to see it. His reason told him (and the reason he gave was) that on recognised principles the asserted phenomenon could not happen. But that was precisely its point of interest, and that was why Crookes with his instinctive sagacity conceived that such things held within them the germ of a great science of the future.

In Crookes's case the germ still remains unfructified by orthodox science. In Hughes's case the germ was rediscovered and has borne fruit a million-fold. But this is to anticipate. Suffice it now to direct attention to the collection of Hughes's apparatus now unearthed by the energy and piety of Mr. Campbell Swinton, and exhibited in the Science Museum at South Kensington. Let us try, however, to avoid imitating the mistakes of our revered scientific ancestors: though I admit it is a difficult task. So much rubbish is brought to our

[1] See also NATURE, vol. 39, pages 471-474.

notice that we are bound to run the risk of neglecting a jewel among the chaff.

These spasmodic observations, however, are not exactly discoveries: they were more akin to vague intuitions. The first and gigantic step in the real discovery was made by Clerk Maxwell, in or about 1865: and he made it in mathematical form, not in experimental actuality, by one of those superhuman achievements which are only possible to our greatest mathematical physicists. He did not discover either the way to generate ether waves, or to detect them; but he did give their laws: he legislated for them before they were born. He knew the velocity with which they must move, and gave implicitly, though without elaboration, the complete theory of their nature.

Up to his time the nature of light was unknown. All the other theories of light had attempted to explain it on mechanical principles, like the vibrations of an elastic solid. Light was known to consist of transverse waves: the wave-length and the frequency of oscillation could be determined. But no one knew what was oscillating, nor what the mechanism of propagation was. With extraordinary genius Fresnel and MacCullagh had explained the phenomena of light in all detail as regards reflection, refraction, diffraction, interference, and polarisation. But the nature of the waves was unknown; and the elastic solid theory, though fascinating, was felt by those who dived most deeply into it to contain some flaw, and to be, strictly speaking, unworkable. Light did not seem explicable on dynamical principles—the principles which were so fruitfully devised by Galileo and Newton for dealing with ordinary matter.

MacCullagh's theory indeed was not dynamical, and in that respect had some advantage. But it was also vaguer and less definite on that account; though, being thus indefinite and yet enabling results to be achieved, it was less liable to be upset and replaced by future discovery.

To Clerk Maxwell we owe the epoch-making discovery that light was not a mechanical oscillation at all, that the ordinary mechanical properties of matter did not apply to it, but that it was explicable solely and wholly in terms of electricity and magnetism. It is impossible to sum up his discovery in a few words; but roughly we may say that the most obvious outcome was:

(1) That if electric waves could ever be generated they would travel with the velocity of light.

(2) That light was essentially an electromagnetic and not a mechanical phenomenon.

(3) That the refractive index of a substance was intimately related to its dielectric coefficient.

(4) That conductors of electricity must be opaque to light.

Maxwell showed further, though he did not then express it in language of this character, that the ether had two great and characteristic constants, of value utterly unknown to this day, though guessed at by a few speculators like myself;—one of them the electric constant of Faraday called K; the other the magnetic constant of Kelvin called μ. It was impossible then, and it is impossible now—though it is not likely always to remain impossible—to determine the value or even the nature of either of these constants. But Maxwell did perceive a way of measuring their product; and he was the first to measure it. Their product is known; and it is equal—as he showed it must be—to the reciprocal of the square of the velocity of light.

Well now, this great discovery aroused in us young physicists the keenest enthusiasm. In the early seventies of last century—I think about 1871 or 1872—I remember discussing it with the man we all now know and honour, J. A. Fleming, who at that time was a fellow student with me in Prof. Frankland's advanced chemical laboratory at the brand-new College of Science, South Kensington. A year or two later, at Heidelberg, I studied Maxwell's treatise pretty thoroughly, and formed the desire to devote my life if possible to the production and detection of Maxwell's electric waves.

I used to discuss the possibility of producing these waves with my great friend, G. F. FitzGerald, whose acquaintance I made at the meeting of the British Association in Dublin in the year 1878; and he wrote some mathematical papers discussing the possibility of producing such waves experimentally. I myself also spoke at the British Association about them, in 1879, 1880, and again in 1882 at the Royal Dublin Society. FitzGerald, as I say, examined mathematically what then seemed the abstruse question of electric wave production; and after some hesitation came to the conclusion that direct artificial generation of waves was really possible on Maxwell's theory, in spite of certain recondite difficulties which at first led him to doubt it. (See "Scientific Writings" of FitzGerald, edited by Larmor, pp. 90-101.) Indeed one of his papers on the subject was originally entitled "On the Impossibility of Originating Wave Disturbances in the Ether by Means of Electric Forces." The prefix "im" was subsequently dropped; although his first, or 1897, paper concluded thus:

"However these [displacement currents] may be produced, by any system of fixed or movable conductors charged in any way, and discharging themselves amongst one another, they will never be so distributed as to originate wave-disturbances propagated through space outside the system."

In 1882 FitzGerald corrected this erroneous conclusion, and referred to some early attempts of mine at producing the waves. ("Scientific Writings," p. 100.) I state all this in order to emphasise the difficulty which in those early days surrounded the subject on its theoretical as well as on its practical side.

In 1883, at the Southport meeting of the British Association, FitzGerald took a further step and surmised that one mode of attaining the desired result would be by utilising the oscillatory discharge of a Leyden jar—the theory of the oscillations of which had been worked out, partly by Helmholtz and more fully by Lord Kelvin, 30 years before—if only we had the means of detecting such waves when they were generated.

Production of Waves.

In 1887 and 1888 I was working at the oscillatory discharge of Leyden jars (initially in connexion with the phenomena of lightning), and—with the assistance of A. P. Chattock—I then found that the waves could be not only produced but also detected, and the wave-length measured, by getting them to go along guiding wires adjusted so as to be of the right

length for sympathetic resonance. Thus I obtained the phenomenon of electric nodes and loops, due to the production of stationary waves by reflection at the distant end, and in my own mind thus verified Maxwell's theory. (I gave a brief account of this work, with calculations of wave-length, in *The Electrician* for September 21, 1888, page 623. Many other passages of early history can be found in the same volume about that date. It was an important year.)

Transmission along wires popularly sounds different from transmission in free space, but it was well known to me that the process was the same, and that the waves travel at the same speed, being only guided by the wires, much as sound is guided in a speaking-tube, without the velocity of transmission being to any important extent altered. The theory is given near the end of my paper—an important one as I think, and as Silvanus Thompson agreed—in the *Philosophical Magazine* for August 1888, where the experimental production of much shorter waves is also foreshadowed.

The beginning of my experiments was reported to the Society of Arts in April 1888; they are recorded, as said above, in the *Phil. Mag.*, and they were more completely described orally at the British Association at Bath that year. (See the *Electrician*, vol. 21, pp. 607-8, September 1888.)

In that year, also, I heard for the first time of Hertz's brilliant series of experiments, where, by the use of an open-circuit oscillator, he had obtained waves in free space, and by reflection had also converted them into stationary waves and observed the phenomena of nodes and loops, and measured the wave-length.

Attention was directed to these experiments of Hertz by FitzGerald in his presidential address to Section A of the British Association meeting at Bath in 1888. No wonder they interested him; for they showed that his method of utilising the oscillatory discharge of a Leyden jar was effective; and, to the surprise of all of us, including Hertz himself, that the waves from an opened-out condenser had sufficient power to generate sparks in an insulated conductor upon which they impinged; the detecting conductor, as generally used by Hertz, being in the form of a nearly closed circle with a minute spark gap at which the scintilla appeared. The radiating power of even a small Hertz oscillator was calculated by me in a subsequent paper (*Phil. Mag.* for July 1889, p. 54), and was found to be 100 horse-power, while it lasted. The duration was excessively short, for, at that rate, practically all the energy was expended in a single swing (about the 100-millionth of a second), but its power of producing little sparks was explained.

This work of Hertz was splendid. He was then professor at Carlsruhe, still quite a young man. He had been trained under Helmholtz; and I had made his personal acquaintance in Berlin when I went to call on Helmholtz in 1881, on a tour of the universities of the Continent. He was then Helmholtz's demonstrator, and was thought highly of by that great master. He could speak English, and was very friendly. I did not see him again till some time after the publication of his great discovery.

Hertz was not at that time fully acquainted with Maxwell's theory, although he knew his equations better than any other German except Helmholtz. Maxwell had not then made any serious impression on the Continent. Even Hertz does not seem at first fully to have realised what he was doing, and did not use the words "electric waves." That title was attached to his subsequently translated book at the suggestion of Lord Kelvin. He spoke about the *out-spreading of electric force*; somewhat as Joseph Henry had done. That was the title of his book. He worked out the phenomena he observed with extraordinary skill, both experimentally and mathematically, rapidly perceiving that Maxwell's theory could be applied to them, and that it might be elaborated in detail so as to include the whole of his phenomena. He it was who drew those accurate diagrams of the genesis of the waves, showing what is happening near the oscillator at every phase—diagrams which now appear in most text-books and of which the upper half is represented as scouring across the country. He knew that true waves were not emitted till beyond a quarter-wave length from the source. He knew how they were polarised, and how their intensity differed in the equatorial and polar directions, and how it varied with what may be called latitude. In fact he rapidly came to know all about these waves. As to us, we knew not which to admire most—his experimental skill when working with a tiresome and irritating mode of detection; or his mathematical thoroughness in ascertaining the laws of their propagation. A synopsis of his equations will be found clearly cited in Preston's "Theory of Light," as well as in other books. I translated some of his papers into NATURE. Never was there the smallest iota of jealousy between us, or anything but cordial and frank appreciation. Maxwell and Hertz are the essential founders of the whole system of wireless. That is to say, they constructed the foundations solidly and well. Of the super-structure—splendid as it is now—we are as yet far from seeing the completion.

In March 1889 I lectured to the Royal Institution on "The Oscillatory Discharge of a Leyden-jar," and incidentally exhibited many of the effects of waves, both on wires and in free space, with overflow and recoil effects. But there was nothing akin to *signalling* exhibited in this lecture, as there was in the subsequent lecture in 1894.

Nevertheless, Sir William Crookes, on the strength of these experiments—which he mentions—wrote a brilliant article in the *Fortnightly Review* for February 1892 (vol. 51, p. 173) in which he foreshadows actual telegraphic accomplishment by that means, and indicates also the possibility of tuning or selective telegraphy, which was not actually born till 1897. He is evidently impressed with the experiments both of Hertz and of myself, and he quotes from my *Phil. Mag.* paper of August 1888 in confirmation and illustration of his prevision. For he says—after speaking of choosing wave-length with which to signal to specific people—"This is no dream of a visionary philosopher. All the requisites needed to bring it within the grasp of daily life are well within the possibility of discovery, and are so reasonably and clearly in the path of researches now being actually prosecuted in every capital of Europe, that we may any day expect to hear they have emerged from the realm of speculation into that of sober fact." Then he goes on—evidently referring to the experiments of D. E. Hughes, at which

he must have been present[3]—"Even now indeed telegraphy without wires is possible within a restricted radius of a few hundred yards, and some years ago I assisted at experiments where messages were transmitted from one part of a house to another, without any intervening wire, by almost the identical means here described."

That article appeared in 1892, and was an anticipation of genius. Too little appreciation is felt to-day for the brilliant surmises and careful and conscientious observations of a great experimental worker like William Crookes; and on some of his researches orthodox science still turns its weighty and respectable back.

Other Methods of detecting Waves.

In 1889 I had come across the effect of cohesion under electric impetus, and employed it to ring a bell under the stimulus of the overflow of a Leyden jar, as described in my paper to the Institution of Electrical Engineers in 1890 (vol. xix. pp. 352-4, where D. E. Hughes's comment on it is also recorded). In 1893 I heard—through a demonstration by Dr. Dawson Turner at Edinburgh—of Branly's filings-tube—an independent discovery of M. Branly, which really constituted an improvement on the first rough coherer idea. What I had called a coherer was not this, but a needle-point arrangement, or the end of a spiral spring touching an aluminium plate, which was and is extremely sensitive, but rather unmanageable.

With a Branly's filings-tube I made many more experiments, developing the subject; and on the untimely death of Hertz I determined to raise a monument to his memory by a lecture at the Royal Institution on these experiments (Friday, June 1, 1894), which I styled "The Work of Hertz"—meaning that it was a direct outcome and development inspired by that work. I soon found that the title was misleading, so that in the next edition I changed it into "The Work of Hertz and some of his Successors," and afterwards changed it still further into "Signalling across Space without Wires"; for that, of course, is what was being done in laboratory fashion all the time. The depression of a key in one place produced a perceptible signal in another—usually the deflection of a spot of light—and, as I showed at Oxford, also in 1894, employing a Thomson marine speaking galvanometer lent me by Alexander Muirhead, a momentary depression of the key would produce a short signal, a continued depression a long signal;—thus giving an equivalent for the dots and dashes of the Morse code—if the filings-tube were associated with an automatic tapper-back. One form of such tapper-back was then and there exhibited—a trembler or vibrator being mounted on the stand of a receiving filings-tube. This was afterwards improved, with Mr. E. E. Robinson's help, into a rotating steel wheel dipping into oiled mercury. Our aim was to get signals on tape, with a siphon recorder, and not be satisfied with mere telephonic detection. We succeeded; but more rapid progress would have been made had we stuck to the telephone, as wiser people did.

[3] Colonel Crompton now tells me that the experiments to which Crookes was probably referring were conducted not by Hughes but by Willoughby Smith, who seems to have demonstrated that some sort of communication was possible in this way.

Telegraphy 1894 to 1896.

My Royal Institution (1894) lecture was heard by Dr. Muirhead, who immediately conceived the desire to apply it to practical telegraphy. When my lecture was published—as it was in the *Electrician*, with diagrams roughly depicting the apparatus shown, drawn (some of them) skilfully but not always quite correctly, by the then editor of the *Electrician*, Mr. W. H. Snell—it excited a good deal of interest; stimulating, to the best of my belief, Capt. (now Admiral Sir Henry) Jackson, Prof. Righi, and Admiral Popoff to their various experimental successes which have been elsewhere described.

I was too busy with teaching work to take up telegraphic or any other development; nor had I the foresight to perceive, what has turned out to be, its extraordinary importance to the Navy, the Merchant Service, and indeed Land and War service too. But fortunately in Italy there was a man of sufficient insight to perceive much of this, and with leisure to devote himself to its practical development. In 1896 Signor Marconi came to this country—and the rest is public knowledge.

Man and the Ice Age.[1]

By Prof. W. J. Sollas, F.R.S.

THE great advance recently made in our knowledge of the Quaternary epoch begins with the observations of General de Lamothe on the ancient shore-lines which run along the coast of Algeria at heights of about 100, 60, 30, and 20 metres above the existing sea-level. They maintain their course with such remarkable uniformity that M. de Lamothe was unable to regard them as due to elevation of the land, and consequently attributed them to changes in the level of the sea, and was thus led to predict that similar shore-lines would be discovered on the opposite coast of the Mediterranean and particularly in Provence; a prediction which was subsequently verified by Prof. Depéret.

Next Prof. Gignoux, a friend and former pupil of Prof. Depéret, made a detailed investigation of these shore-lines and their associated deposits in the Western Mediterranean, and embodied his results in a masterly monograph.

Finally, Prof. Depéret himself extended these investigations to the Eastern Mediterranean and the west coast of the North Atlantic Ocean. In a comprehensive review of the whole subject he proposed the following classification of the Quaternary deposits, based on the four marine terraces of de Lamothe.

1. Sicilian (Döderlein). Coast-line at from 90 to 100 m. The most perfect example of this stage is afforded by the Conca d'Oro or basin of Palermo, an ancient bay of the Mediterranean now filled up with Quaternary deposits. They commence with a blue clay containing near its base the famous fauna of Ficarazzo, which points to cold conditions and a depth of 90 metres. Traced towards those localities where the sea was clearer, the clay passes into a Polyzoonal

[1] A lecture delivered to the Geological Society of London on January 10.

limestone resembling our Coralline crag, while towards the shore it becomes sandy. Ascending in the series, the sand increases and finally passes into conglomerates, which at the summit (90 m.) extend over a rocky platform bored by Lithodomus and encrusted with barnacles—to end against the foot of steep cliffs which are undercut and penetrated by sea caves.

The Sicilian stage is sharply marked off from the Calabrian (Upper Pliocene) by a stratigraphical unconformity and a fauna which is distinguished by the disappearance of many Pliocene mollusca, and the advent of many "cold" species from the North Atlantic. These were brought probably by a cold marine current. At Reggio the Sicilian terrace has yielded an entire skeleton of *Elephas antiquus*.

2. MILAZZIAN (Depéret). Coast-line at from 55 to 60 m. The deposits of this stage are chiefly littoral with a fauna indicating a temperate climate, but warmer than that of the existing Mediterranean.

3. TYRRHENIAN (Issel). Coast-line at 28 to 30 m. This includes the well-known Strombus beds (*Strombus bubonius*) which are found all round the Mediterranean. The fauna is characterised by "warm" species, such as still live off the coast of Senegal and the Canary Islands.

4. MONASTIRIAN (Depéret). Coast-line 18 to 20 m. This is named from the city of Monastir in Tunisia, adjacent to a locality very rich in fossils of the stage. The fauna is almost identical with the Tyrrhenian, but on the north coast of the Mediterranean contains no "warm" species.

THE FOUR CORRESPONDING RIVER TERRACES.

General de Lamothe has shown that the four Quaternary beaches or shore-lines of Algeria correspond with the four Quaternary terraces of the river Isser in Algeria, and Prof. Depéret has similarly identified the Quaternary river terraces of the Rhone with the ancient beaches of Provence.

Thus the river terraces were determined by the base level of erosion, *i.e.* in the first place by the position of the sea-level at the time of their formation.

They are thus liberated from their supposed dependence on the four glacial episodes of Prof. Penck. This distinguished investigator had, as is well known, attributed the transport of the material of which they consist to the action of the comparatively feeble rivers which issued from the moraines of the glaciers at their full extension during a glacial episode,—a view scarcely inconsistent with palæontological evidence.

Commont has correlated the four terraces of the Somme with those of the Rhine, and de Lamothe has correlated them with the four Quaternary sea-levels. But the three lower terraces of the Somme, *i.e.* the first or Monastirian, second or Tyrrhenian, and third or Milazzian, all contain in their lowest deposits a warm fauna, which in the case of the lower two includes Hippopotamus—an animal which certainly was not swimming in the Somme at a time when Switzerland and the Baltic buckler were covered with ice and ice was floating in the English Channel. Messrs. Hinton and Kennard have further shown that a warm mammalian fauna characterises the greater part of the terraces of the Thames.

Thus both marine and river terraces unite in proclaiming a warm climate and so far, apart from the Sicilian, we have encountered no signs of an Ice Age.

CONNEXION OF THE TERRACES WITH THE MORAINES.

We turn then to the moraines which afford evidence of the intercalation of glacial episodes in the otherwise genial climate of the Quaternary age. Prof. Depéret considers that he has proof of the association of the Milazzian terraces with the external moraine of the Rhone (Mindel), of the Tyrrhenian with the intermediate moraine (Riss), and of the Monastirian with the internal moraine (Würm). This association by no means implies synchronism, but it enables us to assign the several moraines to their respective stages.

From the point of view we have now reached it will be perceived that the term "Great Ice Age" is a misnomer, and that instead of speaking of a glacial age interrupted by genial episodes, it would be far more in accordance with fact to speak of a genial age interrupted by glacial episodes.

Since these glacial episodes were quite certainly intercalated it will naturally be asked why they are not more obviously represented in the fauna of the Quaternary age. The answer to this is that the remains of a cold fauna are by no means infrequent, but the gravels at the base of a terrace are not the place to look for them. It is to the slopes between the terraces that we should turn, for it is these which correspond with glacial episodes, and when, as generally happens, they are covered with löss we find in it the bones and teeth of such cold-loving species, as we might expect.

It may further be pointed out that terraces, both marine and fluviatile, mark a stationary level of the sea when deposits were accumulating, in which the contemporary warm mammalia might easily be preserved.

In the intervals when the sea-level was changing the work of denudation ruled supreme and undisturbed deposits were formed but sparingly. Now and then no doubt the bones of some animal belonging to the cold fauna might escape destruction and find burial in a marine terrace along with the warm fauna proper to it, and thus possibly have arisen some of those perplexing anomalies of distribution with which we are only too familiar.

REGRESSIONS.

The movement of the sea-level does not appear to have been a simple fall from the Sicilian to the Milazzian coast-line and from the Milazzian to the Tyrrhenian; there is evidence to show that it fluctuated (Fig. 1), first

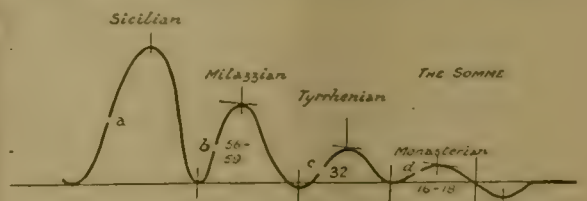

FIG. 1.—Oscillations of the Quaternary sea-level. *ab*, Sicilian stage; *bc*, Milazzian; *cd*, Tyrrhenian; *d* to Neolithic peat, Monastirian. The numbers indicate the heights of the marine terraces in metres.

sinking from the Sicilian to somewhere not far from the existing sea-level and then rising to the Milazzian, and similarly for all the succeeding stages.

Chronology of the Human Family.

The researches of Mr. Reid Moir have made us familiar with the existence of some member of the Hominidæ in the Red Crag, *i.e.* in the Calabrian stage of the Pliocene system, and if Prof. Depéret is right in referring the Forest Bed to the Sicilian, man seems to be also represented in this stage.

In the Milazzian (third terrace of the Somme) human artefacts are found associated with a warm fauna. Some of them are primitive forms of the Chellean boucher, and the industry as a whole is known as the Strepyan or Pre-Chellean.

The Tyrrhenian (second terrace of the Somme) affords the typical Chellean industry. It was indeed from this stage at Abbeville that Boucher des Perthes obtained the so-called "coup de poing" by which he established for the first time the existence of man at this remote period.

In the Monastirian, represented by the lowest gravels of the first terrace, the Chellean attains its final stage of evolution. It is still associated with a warm fauna. But these gravels are "ravinées" by a later one which brings with it Acheulean implements and the mammoth. If our preceding correlations are correct, the Acheulean must evidently be referred to a later stage of the Monastirian when the Würm glaciation was beginning to make itself felt. The Mousterian and all the succeeding industries of the Upper Palæolithic would then belong to the closing days of the Monastirian and the final retreat of the ice.

The interpretation seems to represent the present state of our knowledge, but it is not without its difficulties; one of the most perplexing is suggested by the "warm" Mousterian of Commont. More than one explanation may be offered of this, but the question may well be left to future research.

Comparison of the Coast-Lines of the Northern and Southern Hemisphere.

A eustatic movement of the sea-level is by itself unproved and unlikely, but a general deformation of the globe might well produce effects involving such a movement. That epeirogenic movements cannot be excluded is shown by the fact that the Tyrrhenian coast-line is deformed by local disturbances so that in the Strait of Messina it stands at 100 m. instead of 30 m., and in the Isthmus of Corinth even reaches 300 m. The Quaternary age was indeed by no means so reposeful as seems to be generally assumed; it includes movements of the earth's crust affecting wide areas and on no inconsiderable scale, as is shown by the recent observations of Prof. Bosworth in Peru, and Dr. Molengraaff in the East Indies.

This immensely complicates our problem. Prof. Depéret has sketched in bold outline a remarkable and suggestive history of the Quaternary age. To work it out in all its details will be the arduous task of more than one generation of geologists.

That a general deformation of the globe was in progress during Tertiary and Quaternary times is suggested by the general presence of raised beaches on both sides of the equator. On the north, General de Lamothe determined the existence of ancient coast-lines in Algeria at 325, 255, 204, 148, 108, 60, 30, and 18 m. On the south, they have been observed in Mejillones Bay, Chile, at 320-300, 225, 133, 111-108, 40, and 15-18 m.

It looks as though the earth accomplished its contraction by pulsations.

Obituary.

Prof. Paul Jacobson.

ON January 26 the death occurred at Berlin of Prof. Paul Jacobson, who was widely known as the general secretary of the German Chemical Society and as the editor of important chemical works. He was born on October 5, 1859, at Königsberg in Prussia, and he studied under A. W. Hofmann at Berlin and Victor Meyer at Göttingen. In that university he became a lecturer, and followed Victor Meyer to Heidelberg, where he became professor. Jacobson carried out a number of researches in the field of organic chemistry, especially on azo- and hydrazo-compounds, which earned him the reputation of a careful and original research worker. At the same time he began with Victor Meyer the "Lehrbuch der organischen Chemie," in which these two workers have put on record an immense amount of knowledge and experiences. After the early death of Victor Meyer, Jacobson continued to work alone, unfortunately without being able to finish it.

In 1897 Jacobson removed to Berlin as editor of the Berichte der Deutschen Chemischen Gesellschaft and general secretary of the society. He transacted the business of this society with indefatigable industry and perfect tact until September 1911. He then became scientific editor of the Abteilung für Sammelliteratur, which was founded by the society for the purpose of re-issuing F. Beilstein's "Handbook of Organic Chemistry" and M. M. Richter's "Lexicon of the Carbon-Compounds," and between 1900 and 1906 Jacobson edited five supplementary volumes to the third edition of Beilstein's Handbook. Then he commenced the fourth edition of this standard work, which is to be completed in the near future. The new editions of M. M. Richter have been continued under the supervision of Jacobson by R. Stelzner, as "Literaturverzeichnis der organischen Chemie."

The death of Paul Jacobson will be deeply regretted by all who came to know him in the meetings of the Society and at international congresses. Scientific research suffers a great loss by his death.

Prof. W. N. Parker.

THE death occurred on February 22, at the age of sixty-five, at his residence at Cardiff, of Prof. W. N. Parker, emeritus professor of zoology at the University College of South Wales and Monmouthshire.

Prof. Parker was a pupil of Huxley and for a time acted as his demonstrator. During 1881 and 1882 he

was lecturer in biology at University College, Aberystwyth. He joined the staff of the University College of South Wales and Monmouthshire when it opened its doors in 1883, and retired in September 1922. He came of an illustrious family, being a son of the late Prof. W. K. Parker, and a brother of the late Prof. T. J. Parker. He married a daughter of the late Prof. August Weismann, who survives him, and leaves a family consisting of a son and two daughters.

Prof. Parker was for many years president of the biological section of the Cardiff Naturalists' Society and a member of the science committee of the National Museum of Wales. To the latter institution he presented a valuable collection of zoological material a few months prior to his death. In collaboration with his brother he wrote Parker and Parker's "Practical Zoology." He also translated into English Weismann's "Germ Plasm" and an abbreviated form of Wiedersheim's "Vergleichende Anatomie der Wirbeltiere." In addition, he published original papers on the following subjects: "Anatomy and Physiology of Protopterus," "Poison-organs of Trachinus," "The Structure of the Young of *Echidna aculeata*," "Persistence of the Left Posterior Cardinal Vein in the Frog, with Remarks on the Homologies of the Veins in the Dipnoi," "The Respiratory Organs of Rhea," "On some Points in the Anatomy of the Indian Tapir (*Tapirus Indicus*)," "The Anatomy of the Cæcum in the Rabbit (*Lepus cuniculus*) and Hare (*Lepus timidus*)"; in collaboration with F. M. Balfour, "On the Structure and Development of *Lepidosteus*"; and in collaboration with T. H. Burlend, "On the Efferent Ducts of the Testis in *Chimæra monstrosa*."

Prof. Parker devoted himself for nearly forty years to the interests of the College and University and to the development and organisation of the zoological department. It is impossible to speak too highly of the courage and determination which he brought to bear upon his work in the face of great difficulties in the early days of the College. He will be sadly missed by a large body of former students who passed through his hands, in whose personal welfare, both in the department and outside, he always took the keenest interest. The news of his death will be received with great regret by a large circle of friends and former colleagues.

J. H. L.

MR. F. J. LLOYD.

THE death of Mr. Frederick James Lloyd on February 8 removes an interesting figure from the ranks of the older workers in agricultural science in this country. Mr. Lloyd was born at Sketty, near Swansea, in 1852, and was educated at Bristol Grammar School. After leaving school he proceeded, for family reasons, to study law, but, showing a natural aptitude and interest in science, he soon rejected a legal career and found an opening in the laboratory of the late Dr. Voelcker. The training received there during the next four years was supplemented by evening studies at King's College, London, and subsequent experience in chemistry during a sojourn in Germany. On his return to England he became successively chief assistant to Dr. Thomas Stevenson, of Guy's Hospital, and at the laboratory of the Royal Agricultural Society, ultimately setting up in practice on his own account as an agricultural chemist.

Mr. Lloyd's knowledge of physiology and agricultural chemistry thus acquired led him naturally to a special interest in the subject of dairying, with which he became still more closely identified on the death of Dr. Voelcker by his appointment as consulting chemist to the British Dairy Farmers' Association. His close connexion with that body lasted throughout his life and directed his attention to questions of milk production and the feeding of dairy stock in relation thereto. In due course he began a series of investigations on the manufacture of Cheddar cheese, undertaken on behalf of the Bath and West and Southern Counties Agricultural Society, which proved very helpful to cheese-making farmers of the West of England and brought him into contact with the special agricultural interests of that area. Cider-making particularly attracted his notice. In association with Mr. Neville Grenville, and again on behalf of the Bath and West Society, he started experiments designed to improve the methods of manufacture then current on farms. These extended over some ten years and resulted in the establishment of the National Fruit and Cider Institute at Long Ashton in 1903, Mr. Lloyd acting as director until 1905. This Institute, now associated with the University of Bristol, and serving as its Agricultural and Horticultural Research Station, has been developed by the Ministry of Agriculture to function as the senior Fruit Research Station for this country, and stands as a direct result of Mr. Lloyd's work.

Mr. Lloyd lived also to see the establishment of the Research Institute for Dairying at Reading. His pioneer studies on both the subjects with which he was so closely identified have thus found fitting recognition.

Much of Mr. Lloyd's work was published by him in the form of a series of reports in the Journal of the Bath and West Society, of which for some twenty years he was associate editor. Those relating to cider were republished later by the Ministry of Agriculture. He also, while holding an appointment as lecturer on agriculture at King's College, London, published his lectures in book form under the title of "The Science of Agriculture," a volume which has been translated into several languages.

WE regret to announce the following deaths:

Prof. A. S. Butler, lately professor of natural philosophy in the University of St. Andrews, on March 2, aged sixty-eight.

Sir Ernest Clarke, until 1905 secretary of the Royal Agricultural Society of England and the first lecturer in agricultural history in the University of Cambridge, on March 4, aged sixty-seven.

Prof. B. E. Fernow, emeritus professor and dean of the faculty of forestry at the University of Toronto, and first chief forester of the United States, on February 6, aged seventy-two.

Prof. G. Lefevre, professor of zoology in the University of Missouri, on January 24, aged fifty-nine.

Prof. Vladimir M. Shimkevich, professor of zoology in the University of Petrograd.

Rev. William Wilks, for twenty-five years secretary of the Royal Horticultural Society and the producer of the well-known Shirley poppies, on March 2, aged seventy-nine.

Current Topics and Events.

MUCH excitement was recently created all over the world by the sensational headline, "Cause of influenza discovered at Rockefeller Institute, says Dr. Flexner." The announcement was given a prominent position in the daily papers and everywhere was lauded as one of the greatest medical discoveries known. Almost alone among our contemporaries we stated the actual facts of the work of Olitsky and Gates, the reputed discoverers of the long-sought-for microbe of influenza, and we recommended the adoption of a cautious reserve until further data were revealed. Some of the inner history of this latest American press boom are now published in an editorial in the *Journal of the American Medical Association* (February 10), which has the greatest circulation of the medical papers of the United States and is a journal of the highest repute. It seems that after the sensational announcement above, the *Journal* telegraphed to Dr. Simon Flexner, who replied that his announcement was merely a summary of papers already published by Olitsky and Gates in the ordinary way in the *Journal of Experimental Medicine*. The summary was prepared for the New York State Department of Health. Dr. Flexner states that some one in the State publicity department had headlined the summary without his knowledge. Now that the actual statement of Dr. Flexner has appeared in the Health News Service, it is seen to be nothing that has not been known for the last three years, and as the *Journal of the American Medical Association* points out, the "organism cannot be said to have been conclusively shown to be the cause of the condition known as epidemic influenza," a view which we ourselves independently printed. In justice to the Press it is stated that in this instance it was not to blame, but it is not stated who was. The *Journal* deprecates this method of publication, leading as it does to false hopes for thousands of sufferers, and to the ultimate discredit of real advances in medical science.

TELEGRAMS from New York appeared in several newspapers of February 28, announcing the discovery of a fossilised human skull in the province of Santa Cruz, Patagonia. The *Times* of March 1 published particulars relating to the skull, which were obtained by its correspondent at Buenos Ayres from the discoverer, Dr. Wolf, formerly of the Canadian Geological Survey. The skull, it appears, was found not by Dr. Wolf but by a settler seven years ago in sand-hills in the pampas lying some twenty miles to the west of the port of Santa Cruz. The discoverer reports it to be "petrified" and "probably of tertiary origin." As regards its characters, all that is to be learned is that it is "long in proportion to its width," that its "frontal eminences are well marked," and that it may be a woman's skull. It is true that there exist in Patagonia deposits of the right age to yield fossil remains of Pliocene man, and on numerous occasions, during the past twenty-five years, claims of his discovery have been made. None has stood the test of inquiry; when the remains proved to be human, it was found that a mistake had been made concerning their geological antiquity; when their antiquity was upheld, the remains proved not to be human. Whether the discovery now announced will prove an exception remains to be seen.

IT is reported that excavations now being carried on at Ur of the Chaldees on behalf of the British Museum and the University of Pennsylvania have brought to light a temple of the Moon God. As Ur was the seat of the worship of deified kings and one of the greatest centres of ancient theology, its further investigation is likely to add considerably to our knowledge of the religious and social life of early Mesopotamia. The site and the purpose of the temple were first identified through the interpretation by Rawlinson of four cylinder seals discovered in 1854 by J. E. Taylor, who located the temple tower and excavated an adjacent building and burial mound. Further excavations were carried out by Mr. R. Campbell Thompson in 1918 and by Dr. H. R. Hall, on behalf of the Trustees of the British Museum, in 1919. Dr. Hall also investigated a neighbouring site at Tell el-Obeid, where he found much copper, including several lion heads and a large relief, in a pre-Sargonic building (*circ.* 2900 B.C.) beneath a platform of unburnt brick, probably of Dunghi of Ur (*circ.* 2450 B.C.). The site of Ur itself was occupied from neolithic down to quite late times, the temple having been restored by Nabonidus in the sixth century B.C. As regards its early inhabitants, Mr. Campbell Thompson, in the *Times* of March 1, points out that the present excavations may be expected to throw light upon his suggestion that the people of this area differed in race from the Sumerians. This view is based upon the character of the fragments of hand-made, painted pottery found by himself and Dr. Hall at Ur, Eridu and Tell el-Obeid, which is identical with that discovered by de Morgan at Susa in Elam. This latter, in turn, is referred to a similar, but rougher, type found at Anau in Turkestan.

A WELL-PRESERVED dolmen has been discovered by workmen while excavating at the back of a house at St. Ouens, Jersey. Associated with the dolmen was a kitchen midden full of limpet shells and containing an ancient human skull and a round stone for grinding corn. The skull is very much flattened in the frontal region, and it is no doubt on this ground that a very high antiquity, exceeding that of *Pithecanthropus erectus*, has been attributed to it locally, as is stated in a highly coloured report which appeared in the *Daily Mail* of February 26. It is also suggested that the kitchen midden is of mesolithic age. Although the find is of considerable interest, neither supposition appears to be well founded. Shell-fish must always have been, as they are still, an important element in the diet of the islanders, and therefore does not necessarily indicate a mesolithic culture, while the association with the dolmen and a stone for grinding corn would suggest that a very early date in the neolithic period

for the skull is not probable. The flattened appearance of the skull, upon which stress is laid in the report of the discovery, may be due to pathological causes, but more probably is, as often happens, a case of flattening due to post-mortem pressure after burial. Further details of the measurements of the skull will be awaited with interest, as it will be important to note whether, notwithstanding its distortion, it is to be ascribed to the Mediterranean long-headed type.

ON February 12, Prof. Otto Pettersson, director of the Swedish Hydrographic Biological Commission, Gothenburg, celebrated the seventy-fifth anniversary of his birth, and both chemists and oceanographers in this country, to whom his genial personality is so well known, will wish to join in offering him their congratulations and their good wishes for his future prosperity. Having in early life made a European reputation as a chemist, Prof. Pettersson turned his attention to the study of oceanography, and much of the work in that subject during the last thirty years has owed its success to his initiative and inspiration. His name is particularly associated with the foundation in 1902 of the International Council for the Study of the Sea, of which organisation he was president for a number of years. It was largely owing to Prof. Pettersson's influence and efforts that the Council survived the trying period of the European war and has since renewed and extended the valuable co-operative researches which it is conducting in the interests of the fisheries. We rejoice to know that in spite of his advanced age, Prof. Pettersson's zeal for scientific work is in no way abated, and that he remains an active and energetic investigator, more especially of problems affecting the sea.

THE sixth Silvanus Thompson memorial lecture of the Röntgen Society is to be delivered on Tuesday, May 1, by Dr. C. Thurston Holland.

THE gold medal of the Astronomical Society of the Pacific was presented to M. B. Baillaud, director of the Paris Observatory, at the American Embassy in Paris on February 26.

DR. CHRISTOPHER K. INGOLD was awarded the Meldola medal of the Institute of Chemistry, for the second time, at the annual general meeting of the Institute held on March 1.

AN excursion to Devizes and Salisbury Plain, extending from May 18 to 21 inclusive, particulars of which are obtainable from Mr. B. H. Cunnington, Wiltshire Archæological Society, Devizes, has been arranged by the Prehistoric Society of East Anglia.

THE Medical Research Council has appointed the following scientific committee to organise an investigation into dog's distemper: Sir William B. Leishman (chairman), Mr. J. B. Buxton, Capt. S. R. Douglas, Prof. F. Hobday, and Dr. C. J. Martin. A member of the Council's staff will act as secretary to the committee, and communications should be addressed to the Secretary, Distemper Research Committee, 15 York Buildings, Adelphi, W.C.2.

THE British Association recently acted in co-operation with a number of other "travelling" societies in requesting the railway companies to revert to the pre-war practice of granting return tickets at single fare and one-third to members attending meetings, on presentation of a voucher. The Association has now been informed that in connexion with its next annual meeting, in Liverpool, September 12–19, this concession will be made by the companies.

AT the meeting of the Franklin Institute of the State of Pennsylvania, Philadelphia, held on February 21, Dr. Lee de Forest received the Elliott Cresson gold medal awarded to him by the Institute for his invention of the three-electrode audion. In presenting Dr. de Forest for this award, his invention was characterised as one of the most important ever made in the field of the electrical transmission of intelligence, and one which through its development has marked a profound revolution in the art of radio communication.

THE tenth annual general meeting of the Institution of Petroleum Technologists will be held at the house of the Royal Society of Arts on Tuesday, March 13, when an address will be delivered by Prof. J. S. S. Brame, the retiring president. The president-elect for the ensuing session is Mr. Herbert Barringer, and the vice-presidents are Mr. Alfred C. Adams, Sir George Beilby, Sir John Cargill, Viscount Cowdray of Cowdray, Mr. Arthur W. Eastlake, and Sir Thomas H. Holland.

AT the annual general meeting of the Optical Society, held on February 8, the following officers and council were elected: *President*: Prof. A. Barr. *Vice-Presidents*: Sir Frank Dyson, Mr. T. Smith, and Mr. R. S. Whipple. *Hon. Treasurer*: Maj. E. O. Henrici. *Hon. Secretaries*: (*a*) Business Secretary, Prof. Alan Pollard, Imperial College of Science and Technology, South Kensington, S.W.7; and (*b*) Papers Secretary, Mr. F. F. S. Bryson, Glass Research Association, 50 Bedford Square, W.C.1. *Hon. Librarian*: Mr. J. H. Sutcliffe. *Editor of Transactions*: Dr. J. S. Anderson. *Council*: Dr. J. S. Anderson, Instr.-Comdr. T. Y. Baker, Mr. W. M. Brett, Prof. F. J. Cheshire, Mr. R. W. Cheshire, Dr. R. S. Clay, Mr. H. H. Emsley, Mr. P. F. Everitt, Dr. J. W. French, Miss L. M. Gillman, Mrs. C. H. Griffiths, Dr. L. C. Martin, Prof. A. W. Porter, Mr. F. Twyman, and Mr. A. Whitwell.

A NEW meteorological observatory at Santa Cruz, Teneriffe, Canary Islands, was sanctioned by Royal Decree in July 1921. It is now announced that the building has been started, and will probably be completed shortly. The fact is noted in the *Meteorological Magazine* for February, and it is stated that the Island of Teneriffe already has a first-class observatory at Izana, situated 2307 metres above sea-level. Being on the direct route from Lisbon to Rio de Janeiro, these two observatories will be of great service to transatlantic aerial navigation. The note adds that a hydroplane station is also to be established on the island.

A MEMORANDUM on the probable character of the weather in north-west India in January, February, and March 1923 was prepared by Dr. G. T. Walker, director-general of Indian observatories, and submitted to the Government of India on January 5. The data which control the amount of rain and snow to be expected are:—(*a*) The recent weather conditions in Persia and north-west India; these are slightly favourable. (*b*) The seasonal change in the upper air in northern India, which is slightly adverse. (*c*) The atmospheric pressure over India in the previous October and November, which is neutral, October being above normal and November below normal. (*d*) Rainfall at Seychelles and Zanzibar; rainfall at Seychelles was in defect in November and December, and at Zanzibar it was in excess in December. On the whole the indications point to a slight defect in the winter precipitation, but the indications are said not to be sufficiently pronounced to justify a forecast of a deficiency.

REFERRING to the obituary notice of Prof. George Lunge in NATURE of February 17, p. 228, a correspondent has pointed out the last paragraph might give the impression that Dr. Hurter was of German nationality whereas he was a native of Schaffhausen, Switzerland. The writer of the notice was concerned rather with the influence exercised at the time by the German universities in providing opportunities, not necessarily for Germans alone, for scientific training as chemists, some of whom came to England to acquire knowledge and experience of the practical applications of the science.

WE have received from Messrs. A. Gallenkamp and Co. a catalogue of "Electrometric Apparatus for determining Hydrogen Ion Concentrations." This includes an apparatus for determining hydrogen ion concentrations both for work of high accuracy and for routine industrial work.

MESSRS. BOWES AND BOWES, 1 Trinity Street, Cambridge, have just issued a very useful catalogue (No. 417) of second-hand books, journals, and portraits of scientific interest offered for sale by them. It contains 1158 titles, which are classified under the following headings: Journals, etc.; Agriculture; Anthropology and Ethnology; Biography; Biology; Botany (including Forestry and Gardening); Geology; Microscopy; Zoology (including Ornithology and Entomology); General Science; Chemistry; Physics (including Einstein Theory); Medical (including Physiology); Portraits.

Our Astronomical Column.

INCREASE OF BRIGHTNESS OF BETA CETI.—There appears to be no reason to doubt the news that this star has brightened by more than a magnitude in the last week or so. The change was first observed by a British schoolboy named Abbott, resident in Athens; being a member of La Société Astronomique de France, he telegraphed to M. Camille Flammarion at Juvisy, whose assistant, M. Quénisset, confirmed the brightening. Apparently further confirmation has been received from the United States. Unfortunately the star is observable in England only by day or in very bright twilight, and the skies have not been propitious for studying it. Data for drawing the light curve are not yet to hand, so that it is premature to speculate on the probable cause of the increase of light. The news hitherto available comes through the daily press; the Astronomical Bureau at Copenhagen has made no communication.

THE ZODIACAL LIGHT.—Mr. W. F. Denning writes:—During the period from about March 8–20 and April 4–18, the zodiacal light may be well observed on clear evenings in the absence of moonlight. It will be visible about two hours after sunset as a faint glow extending upwards, obliquely, through the constellations of the Zodiac, and broadest at its base on the western region of the horizon. It apparently varies from night to night, for its visibility is evidently influenced by atmospheric conditions. Careful observations of the degree of luminosity, positions, and boundaries of the light on successive evenings will be valuable. The most probable explanation of the phenomenon is that it is due to the sun's reflected light on myriads of meteoric particles belonging to systems of little inclination and situated at moderate distances from the sun.

THE SPECTRA OF VISUAL DOUBLE STARS.—Mr. F. C. Leonard publishes in the Lick Observatory Bulletin (No. 343) an important contribution to the study of the spectra of visual double stars. If the components of a double star had a common origin, a knowledge of the spectral relationships existing in different systems, presumably at various stages in the course of evolution, might be expected to disclose the general trend and the comparative rates of development of these stars. It was with the intention of gaining more knowledge on this subject that Mr. Leonard commenced this investigation in 1920. From a study of eighty visual double stars specially observed for this work, he finds that the spectrum of the secondary component of a dwarf star is generally of a later class and that of a giant star is of an earlier class than the primary. In both giant and dwarf stars the greater the difference in magnitude between the primary and secondary the greater is the absolute difference in spectral class.

The spectrum of each component of a double star appears to be a function mainly of its absolute magnitude; or in other words, the spectra of the components of double stars are so related to each other that, with but few exceptions, these systems conform to the Hertzsprung-Russell arrangement for individual stars, plotted according to spectral class and absolute magnitude. In this configuration, the fainter component normally precedes the brighter one, regardless of whether the latter be a giant or dwarf in the order prescribed by the Lockyer-Russell theory of stellar evolution. The two earlier conclusions are special phases or necessary consequences of this generalisation. Thirteen binary systems, all stars of which were dwarfs, indicated that as the sum of the masses of the components increased, their disparity in spectral class approached zero. Of any two stars of unequal mass but of otherwise identical physical properties, that with the less mass will in general pass through its life history in advance of the more massive one.

The Oldest Christian Tomb in India.—Agra, which possesses, in the splendid mausoleum known as the Taj, one of the finest sepulchres in the world, claims also the oldest Christian grave in northern India. It is known as the Martyr's Chapel, the tomb of a rich and very pious Armenian merchant called Martyrose, who died at Agra in A.D. 1611. The inscription on the tomb, now for the first time translated by Mr. Mesrovb Seth in the Journal of the Asiatic Society of Bengal, vol. xvii., 1921, runs: "In this tomb rested the pilgrim Martyrose son of Pheerbashi of Julfa. He died in the city of Agra and gave his goods to God for his soul. 1060 of the Armenian era." The Archæological Department has now restored the tomb of this worthy, a member of the important Armenian community of Julfa in Persia, who came to India as a merchant. An inscription in Persian to his memory has been placed on the tomb.

The Ismaili Sect of Islam.—The important sect of the Ismailis or Assassins, the doctrines of which were preached by the Old Man of the Mountain, has exercised wide influence in Persia. The scattered material collected by historians, travellers, and theologians cannot compare in value with the genuine documents of the sectarian literature, but for five hundred years, when these materials came to an end at the time of the Mongol invasion which destroyed the power of the Assassins, the life of the sect is a blank. Mr. W. Ivanov, who has spent seven years in investigating the beliefs of the sectarians in Persia, has published under the title of "Ismailitiia," a translation of an important text which throws much light on the subject. This has been issued by the Asiatic Society of Bengal as part 1, vol. viii. of its memoirs. It will be interesting to European readers, as the leader of the sect is the Agha Khan of Bombay who did notable service to the Indian Government in the War, and has since devoted himself to the task of calming the agitation which has arisen in India on the Caliphate question.

The Indian Tribes of California.—The University of California, in its series of publications on American archæology and ethnology, has issued a large number of valuable memoirs, but a general survey of the inter-relations of the culture of these tribes has hitherto been wanting. This want has now been supplied by Mr. A. L. Kroeber, an ethnologist to whom we owe several of these tribal memoirs, who has prepared a general sketch under the title of "Elements of Culture in Native California," for the University series (vol. xiii. No. 8), in which he describes the arts of life, social organisation, religion, and ceremonies. This memoir, which gives an excellent survey of the industrial, social, and religious life of a primitive people, will be a valuable book of reference to ethnologists. It is provided with sketch maps, but unfortunately a general index is wanting.

Microbic Transmissible Autolysis.—One of the most interesting developments of modern bacteriology has been in relation to what is now called the Twort-d'Hérelle phenomenon. This has recently been the subject of the Cameron prize lecture given by Prof. J. Bordet, of Brussels, and published in the *Brit. Med. Journal* of February 3. In this lecture the main facts are clearly set forth and particularly the views of Bordet and his co-workers. For those who have not been following the subject specially it may be stated that in 1915, F. W. Twort, Director of the Brown Institution, London, described a peculiar glassy-like change which appeared in colonies of certain micrococci which he had isolated from calf lymph. A minute trace of the glassy agent added to a cultivation of bacteria dissolved the latter, and strange to say, the glassy agent could traverse fine porcelain filters without detriment. In 1917 d'Hérelle observed similar phenomena and regarded them as due to the activity of a living agent which he called "microbe bacteriophage" on account of its power of devouring bacteria. This view he has continued to defend with great vigour. Bordet and Ciuca adopted an entirely different explanation. They do not believe the active substance is a living agent at all but as a product of the bacterium itself induced in the first instance by some external influence and subsequently capable of indefinite transmission. A full treatment of the subject will be found in Bordet's lecture referred to above.

The Spleen.—The functions of this organ are somewhat obscure. It is generally recognised, however, that it has something to do with the destruction of effete red blood corpuscles. A certain proportion of the corpuscles in general circulation are more fragile than the rest, in the sense that when distended by osmosis in hypotonic solutions they burst in solutions of a higher concentration than do the younger, more distensible ones. A recent paper by Bolt and Heeres, in the *Biochemical Journal*, vol. 16, p. 754, shows that after passing through the spleen, blood corpuscles are rendered less resistant, so that a larger proportion become hæmolysed when placed in the stronger salt solutions, that is, the less hypotonic solutions. Thus they withstand distension to a smaller degree than normally. This property is due to the adsorption of some substance supplied by the spleen and can be removed by washing with Ringer's solution. The previous work of Brinkman and van Dam had shown that the fragility of red corpuscles depends on the relative proportion between cholesterol and lecithine in their outer membranes, the former conferring stability, the latter, fragility. Apparently the spleen adds lecithine in larger amount than it does cholesterol.

Curing Sleeping Sickness.—In the *Empire Review* for February Dr. Andrew Balfour has an interesting article entitled "Cure of Sleeping Sickness." He deals largely with the claims of the new German remedy "Bayer 205" and admits that it is the most powerful destroyer of the parasites of the disease so far tested. For a time sleeping sickness and other trypanosome diseases were looked upon as absolutely fatal, while later on partial success was achieved by more than one remedy containing arsenical or antimonial bodies. "Bayer 205" contains neither of these in any form, and although its exact composition is not known, it is suggested that it belongs to the benzidine dye series. It is a white powder, easily dissolved in water, neutral in reaction, without smell, and does not deteriorate on heating. It possesses extraordinary parasitotropic action on trypanosomes, and in minute doses can produce a *sterilisatio magna* in animals heavily infected with these parasites. These results worked out by Haendel and Joetten have been confirmed in man by Mühlens and Menk in Germany and by Wenyon and Manson Bahr in London. Dr. Balfour emphasises the need for chemical research in this country, and lays stress on the necessity for persistence, time, money, and far-sightedness. Ehrlich was fond of summing up the success of scientific researches in what he termed the four G's, *Geld, Glück, Geduld, Geschick*, which comes to the same thing.

RECENT PENTACRINIDÆ.—In the Journal of the Washington Academy of Sciences of January 4 Mr. A. H. Clark publishes a revision of the recent representatives of the crinoid family Pentacrinidæ. For many years the name Pentacrinus has ceased to be applied to any crinoid now living, and now Isocrinus, to which genus most of the modern species were for a time referred, is also considered to be entirely extinct. For the only species that remained—the Atlantic *Pentacrinus wyville-thomsoni*—Mr. Clark founds the new genus Annacrinus.

A NEW BRITISH ENTEROPNEUST.—In the current number of the *Quarterly Journal of Microscopical Science* (vol. 66, part iv.) Prof. Alexander Meek records the discovery of an interesting addition to the British marine fauna. The Enteropneusta have hitherto been represented in British seas, so far as known, only by two species of the genus Dolichoglossus, from the west coast of Ireland and Scotland respectively. The newly discovered species is apparently referable to the genus Glossobalanus, and the name proposed by Prof. Meek is *Glossobalanus marginatus*, the species being regarded as distinct from any previously described. Unfortunately only a single imperfect specimen was obtained, off the coast of Northumberland at a depth of 52 fathoms. It is further suggested that a Tornaria larva sometimes met with in the North Sea plankton may be referable to this species.

POMOLOGY.—A few years ago Mr. E. A. Bunyard, of the well-known Maidstone nurseries, upon his own initiative started a *Journal of Pomology*, in which contributions of very great scientific interest have been published. With its third volume this journal commences its career anew as the *Journal of Pomology and Horticultural Science*, with a powerful publication committee to support the original editor, the financial responsibilities now being transferred to the three horticultural research stations at Long Ashton near Bristol, Cambridge, and East Malling, Kent. In a foreword, Sir A. D. Hall expresses his interest in the new journal and his hope that while providing a medium for the publication of the results obtained by the investigators at these research stations, it may also "gather together new knowledge and experience from all kinds of public and private workers connected with fruit-growing in Great Britain." From the beginning the format of the journal has been good and many of its photographic reproductions exceptionally fine. The first number of the new volume contains a valuable series of papers upon the raspberry. The genus Rubus has long been a stumbling-block to systematists, and Mr. N. H. Grubb appears to have commenced for *Rubus Idæus* the task which the late Rev. Moyle Rogers carried out so thoroughly for *Rubus fruticosus*. Upon a series of characters the large and confusing number of varieties of raspberry grown in Great Britain are arranged within groups and a key given to permit the determination of some of the more important varieties. First importance is attached to the surface characters of the young canes, which fall into two groups, one pubescent, the other glabrous or nearly so; the colours of the spines then provide another valuable character. This important work is certainly a necessary preliminary to any cultural or experimental work with the raspberry. W. Boyes describes the characters of different types of apple-tree shoots, based largely upon the current nomenclature of the French horticulturist. F. V. Theobald describes the apple and plum case-bearer and its treatment. Herbert W. Miles discusses the control of the apple-blossom weevil, and G. S. Peren the value of spraying for the control of the logan beetle.

SURVEYS IN THE EASTERN KARA-KORAM AND KHOTAN.—A detachment from the Survey of India, under Maj. H. Wood, was attached to Dr. F. de Filippi's expedition of 1913 to undertake exploration and geophysical researches in the little-known regions of the Kara-koram at the headwaters of the Shyok and Yarkand rivers. Maj. Wood's report, which was delayed by the war, is now published ("Exploration in the Eastern Kara-koram and the Upper Yarkand Valley. Dehra Dun: Office of the Survey, 1922. 6*s*.). The work included the survey of the Depsang plateau, the San Remo Glacier, from which the River Yarkand proves to drain, and the upper valley of that river. Maj. Wood shows how he ascended what he believes to be the line of an old route leading across the head basin of the Oprang, but Dr. Filippi was forced to abandon his project of exploring that valley. An appendix contains a discussion of historical evidence bearing on certain disused or forgotten routes through the Kara-korams. The report is accompanied by a series of photographic plates and a coloured map, on a scale of 1 to 250,000, of the area surveyed by Dr. F. de Filippi's expedition.

MAN AS AN AGENT IN GEOGRAPHICAL CHANGE.—Some of the ways in which man modifies the surface features of the earth were discussed in a lecture by Dr. R. L. Sherlock, given to the Royal Geographical Society on February 19. Mining and quarrying assist the natural agents of denudation and transform scenery. A calculation of the amount of rock removed in various kinds of excavation by man in Great Britain since the earliest times shows the significance of this work. The total excavation spread over the British Isles would amount to 3·83 inches. This may be compared with Geikie's estimate of the rate of erosion in the British Isles, which is 2·72 inches in 2000 years. Surface subsidence is an important effect of mining operations. Dr. Sherlock showed how this might be prevented or delayed by leaving pillars to support the roof, or by the method frequently adopted in the collieries of Upper Silesia of stowing waste materials in the cavities produced. The accumulation of waste on the surface may be utilised to fill up a foreshore as at Middlesbrough, where 4270 acres have been reclaimed in this manner; or it may form artificial hills. In the Black Country of Staffordshire some 230 million cubic yards of waste have been deposited on 23 square miles. Yet in this case subsidence has probably more than counterbalanced the gain. Under the site of London some 50 million cubic yards have been excavated, but brick or other linings have prevented subsidence. In fact, the level of London has actually risen by the accumulation of domestic and other waste. Excavations have shown this to be the case. On its own debris the height of London grows about one foot a century. It is probable that in three centuries the waste from the coal used in London has amounted to more than 42 million tons. Most of this directly, or indirectly, in the form of bricks and artificial flagstones, has been incorporated in the site of London. Dr. Sherlock also gave examples of man's interference with rivers, and, by means of pumping, with the circulation of underground waters.

OIL IN LACCOLITHIC DOMES.—Of the many geological structures in which petroliferous sediments may be involved, elevated, dome-like masses of rock, resulting from igneous intrusion of the laccolithic type, are rarely productive of oil on a commercial scale, save possibly in certain cases in Mexico. There is, however, no reason *prima facie* why such a structure should not be favourable, unless secondary

mechanical or thermo-dynamical effects on the superincumbent strata seriously influence the stability of organic material within the sediments. Thus it is not surprising to find that the United States Geological Survey is turning its attention to such possibilities in certain areas in the Western States, and a brief paper (Bulletin 736-F) dealing with oil accumulation in laccolithic domes in the Little Rocky Mountains region of Montana (the work of Messrs. A. J. Collier and S. H. Cathcart) is one of the first results of this inquiry. In the cases described, the uplifts are due to intrusions of porphyry, some of which are exposed, others, in the less denuded tracts of country, being still covered by sediments of varying ages, principally Upper and Lower Cretaceous. Of the former, the Eagle sandstone and the Mowry shale are both possible oil-bearing horizons, while the Kootenai formation (Lower Cretaceous) is well known to be favourable elsewhere. One or other of these horizons could be reached by drilling in at least two pronounced domes, the Guinn and the Grouse-Alder domes, within the area described, to the south of the Little Rocky Mountains. The authors do not of course prophesy commercial success for any fields which may be opened up here, but they have indicated the most likely areas in an otherwise discouraging region, and it will be interesting to observe, both from the scientific and industrial points of view, the results of any trials which may ultimately be made as a consequence of their report.

LIGHTING IN MINES.—A striking illustration of the value of good illumination in enabling output to be increased in industrial operations is afforded by some experiments in coal mines described by Messrs. E. Farmer, S. Adams, and A. Stephenson in the Journal of the National Institute of Industrial Psychology. The report of the Miners' Nystagmus Research Committee, issued last year, confirmed the impression that this disease is due mainly to inadequate illumination. The present research shows how the miner's work is hampered and his output affected by deficient lighting. There are two chief drawbacks to most existing miners' lamps, the low illumination afforded and the exposure of the filaments, which, in such dark surroundings, give rise to highly inconvenient after-images on the retina. The authors describe a form of cylindrical shield which has a useful effect in avoiding this form of glare, and also give the results of work for an eight-hour period with the ordinary standard miners' lamp and with a special " porch-light " giving six times as great an illumination. It was shown that the improved illumination led to an increase in output from 2·47 to 2·83 tons, an increase of 14·57 per cent. The experiment serves to show the wide field for improvement existing in lighting conditions in coal mines and the benefits that might be secured by a moderate expenditure on research.

METEOROLOGY AT SOUTHPORT.—Results of meteorological observations at Southport for the year 1921, and the annual report of the Fernley Observatory of the Corporation of Southport, compiled by the meteorologist, Mr. Joseph Baxendell, have recently been issued. The report is published in two editions, copies being circulated by the Southport Corporation, and by the Meteorological Office, Air Ministry. The Borough Observatory of Southport is the longest municipally-maintained meteorological station in the British Isles, observations having continued for the past 50 years. Daily, weekly, and monthly returns are supplied to the Meteorological Office. Much time has been devoted to the comparisons involved in the investigations of meteorological periodicities; among the clearly indicated cycles is one of 5 years, while a rainfall cycle of 53 years is said to be the chief. An appendix gives monthly averages, for 10 years, of the amount and duration of rainfall under different wind directions. It is shown that winds from southerly points are pre-eminently those of the rainy quarter. The most remarkable year during the half-century's existence of the observatory is stated to be 1921, although in the north-west of England it was not so dry as several previous years; the total deficiency of 4 inches of rainfall was trivial in comparison with the extraordinary drought over south-eastern England. For general fine-weather factors there is no known predecessor to equal it, the outstanding feature being the remarkably high mean atmospheric pressure. The underground water-level remained extremely low until the substantial winter rains in the latter part of December. Taken as a whole, the meteorological results will serve well as a guide for observations made by other municipal bodies.

DISTANCE THERMOMETERS.—Messrs. Negretti and Zambra have introduced a type of distance thermometer which appears to get over many of the difficulties and errors to which such instruments have been subject in the past. The new instruments depend on the expansion of mercury in a steel bulb to which a capillary tube of the required length is attached. This tube ends in a coiled Bourdon tube with the free end of which the pointer of the instrument gears directly. The pointer moves over a circular dial about 300° of which are occupied by the scale. The effect of change of temperature of the connecting capillary is eliminated by a wire of invar running down the tube and reducing the volume of mercury to such an extent that the change of its volume with change of temperature is identical with the change of volume of the steel tube. The errors of such an instrument tested at the National Physical Laboratory from 0° to 50° C. at no point of the scale exceeded 0·05° C.

PHOTO-ELASTIC RESEARCH.—In a recent number of the Memoirs of the Society of French Civil Engineers (Bulletin de juillet-septembre 1922) Prof. E. G. Coker gives the text of a lecture, delivered by him last summer in Paris, which contains an up-to-date account of the method of exploring stresses in structures by means of celluloid models examined in polarised light, a method which is at present making rapid progress both here and on the Continent, and bids fair to become indispensable to every scientific engineer. Besides giving a sketch of the method and its general applications, Prof. Coker obtains new and interesting results concerning the testing of cement briquettes under tension, and compares the standard forms of such test-pieces adopted in Britain and France respectively. In particular, he shows that the standard briquettes adopted in both countries for cement tests lead to a strikingly unequal distribution of tensile stress across the middle section of the test-piece, and thereby to serious error in the deduced tensile strength. He suggests, as the result of photo-elastic research, a new shape of standard briquette which is free from this defect. Further illustrations of the method include a discussion of contact stresses and an investigation of the stresses arising from the action of cutting tools, both in the work and in the tool itself. This part of the lecture is partly a restatement of results previously described by the author and Dr. Chakko in the Proceedings of the Institution of Mechanical Engineers in April 1922, but various novel points are introduced.

The British Science Guild.

THE Mansion House was an appropriate *venue* for the great meeting organised by the British Science Guild on February 27 to acknowledge and proclaim the importance of scientific method, scientific knowledge, and scientific research as factors in promoting "national and Imperial interests." In the Egyptian Hall, with its high curved roof, its brilliant stained-glass windows, its serried banners recalling battles and heroes of long ago, the Lord Mayor presided over a distinguished company of representatives of modern science and industry. The first citizen of London is the honoured custodian of many great traditions, among which not the least precious is the city's historic generosity in promoting education and science. The City and its Companies have in the past given freely of their wealth in aid of these great causes, and it is fitting therefore that their faith in science, so amply proved, should stimulate the new crusade for its increased national recognition. Not less significant was the King's message of encouragement which Lord Askwith read to the meeting, welcoming the efforts of the Guild "to stimulate the scientific spirit, and to secure that application of science to industries, commerce, and, indeed, in all fields of human activities, so essential to efficiency and to the closer fellowship of all parts of the Empire."

The Lord Mayor, in his introductory remarks, emphasised the usefulness of the Guild's work of propaganda. When, he said, the British Science Guild was founded in 1905, its first object was stated to be to convince British people, by means of publications and meetings, of "the necessity of applying the methods of science to all branches of human endeavour, and thus to further the progress and increase the welfare of the Empire." Modern civilisation is so closely bound up with the advance of scientific knowledge that all progressive citizens can realise the service which a body like the Guild is able to render to this country and to Imperial development. This is an age of science, when such wonders as X-rays, radium, and wireless telephony, which have added so greatly to human powers and communication, are accepted almost as commonplace parts of our daily life. More scientific work is being carried on now than ever before, and we may expect results which will be of even greater value than those already achieved. British science in several directions leads the world, and it is right that this fact should be more widely recognised. Science stands not only for new devices and powers, but also for accurate knowledge and the right use of man's capacity and individuality. Scientific method must, therefore, be applied to social problems if the true principles of progress are to be determined. The Guild stands for national service in a wide sense: it includes representatives not only of pure and applied science, but also of industry and capital. After the Napoleonic wars, the nation found itself exhausted and impoverished. Our national position was re-established through the steam-engine and the industrial development which followed. We have now to look to the science laboratory to restore our economic position, and even to improved agricultural production. Later in the meeting the same note was sounded by Sir Joseph Cook, High Commissioner for Australia, who pointed out that a vast amount of capital had been wasted through the war, but the loss would soon be made good if two blades of grass could be made to grow instead of one or if the speed of steamships and other forms of transport could be doubled.

The principal resolution was moved by Lord Askwith as president of the Guild and accepted unanimously in the following terms:

"That this meeting, convinced that the progressive use of scientific knowledge is essential to industry and commerce, and that the application of scientific method to all public affairs would ensure increased efficiency and economy, pledges itself to support the efforts of the British Science Guild to promote national and Imperial interests by means of these powerful factors."

A letter of apology for absence was read from Sir Joseph Thomson, which stressed the need for the popularisation of science on the widest possible basis. "It seems to me," Sir Joseph said, "that the remarkable increase in the opportunities for scientific research which has taken place in the last thirty or forty years has not been accompanied by a proportionate increase in the means of bringing matters of scientific interest before the great mass of the people. . . . I do not forget the work of some of the great newspapers in spreading an interest in science by the admirable articles they publish at frequent intervals, but the public I am thinking of does not read the *Times* or the *Morning Post*." A more urgent need was to arouse an interest in science in the bulk of the population, which would facilitate the passage of measures to promote the progress of science in this country. Lord Askwith endorsed this plea and urged also that a great deal more might be done to endow discovery. It was of immense importance, he considered, that men of science without the hope of immediate reward should probe the mysteries of Nature, and that new discoveries should be brought quickly into general knowledge.

The appeal for some further endowment of "problem-solvers"—the elder men of science who devoted their lives to research as apart from the young trained laboratory workers—was vigorously pressed by Sir Ronald Ross. It might be supposed that the discoverer of the cause of cancer or tuberculosis would soon become a millionaire, but he pointed out that Sir David Bruce, who solved the problem of sleeping sickness, was now in Madeira unemployed, and there were three or four others whom he could name. He suggested that the nation should pension scientific discoverers of pre-eminent worth, and allow them to go on working as they pleased.

The vote of thanks to the Lord Mayor and the other speakers was proposed by Lord Askwith and seconded by Lord Bledisloe, who made an interesting speech on the application of science to agriculture. It appears that Continental agriculturists use the results of the researches on fertilisers and plant diseases at Rothamsted more than we do ourselves.

The meeting was a prelude to the launching of a national appeal by the British Science Guild for increased personal and financial support, and an appeal committee has been appointed, of which Lord Askwith is president. The list of members includes many distinguished representatives of science and public life. The director of the appeal is Commander L. C. Bernacchi, physicist of Scott's first Antarctic Expedition. A comprehensive plan of objects and methods has been drawn up and will be widely circulated in due course. The details of the scheme were not announced to the meeting, but the Lord Mayor said at the conclusion of his speech that whatever support was given to it would be returned a hundredfold in national honour and profit.

Research in the Scheme of Higher Education.[1]

By Dr. HERBERT H. HODGSON, The Technical College, Huddersfield.

THE present time is exhibiting none other than a break in the continuity of civilisation. No longer must the production and recognition of supermen be left to chance, since unusual genius, in whatever quarter it may be found, must have a field provided for its activities if our place as a leading nation has to be maintained. It is the province of higher education to discover this genius, a province, which, owing to haphazard evolution, is largely at the mercy of the dilettante, and, as a consequence, not yet in a condition to evolve those power stations of mind without which the necessary creative atmosphere remains ungenerated. The practical results of the German system of higher education have been the creation and development of key industries wherever possible, these ensuring an industrial system which afforded the security of continuous employment of an extremely varied character. This conferred a measure of national stability which was stout enough to defy the whole world for four years, and, but for lack of psychological balance, might have retired the actual winner of an apparently drawn battle.

The industrial exploitation of chemical science by Germany has entirely changed the international situation, inasmuch as a flourishing all-round chemical industry is now essential to the continued success and progress of all great manufacturing activities. This industry dominates the whole trade situation, and no country, however friendly at present, must ever be in a position to dictate by means of it such terms as can spell eventually our decadence and commercial annihilation. An unemployment problem of so vast a magnitude as ours demands the exploration of every reasonable avenue which may provide economic work, a demand which leaves no room for the neglect of key industries to be used against us. This in itself is an answer to the query as to whether the material importance of the organic chemical industry warrants its foundation in Britain. Recent combinations in other countries between firms engaged in key industries are ominous portents for the future.

The greatest key industry is that of synthetic dyestuffs, which, once established permanently, will prove the greatest source of well-being to our nation yet conceived. Its potentialities are bewildering in their immensity and can create and fashion the very future itself, so it becomes imperative that no external nation must be allowed to possess such a weapon as a monopoly. The war demonstrated the temperamental fitness of our countrymen for the dyestuffs industry, and, in spite of the current hostile criticism, I hold with Sir William Pope that only a few years are required for the organisation of a perfect lattice of fine chemical industries.

No industry dependent upon men of science for its progress will be able to survive external competition of a kind which Germany, the United States, and Japan are capable of exerting, unless a creative atmosphere is generated within the walls of our schools and our standards of intellectual attainment are raised to a much higher level than at present obtains. It is not sufficiently realised how much research work has to be done before any tangible results accrue, and therefore a multiplication of agencies is necessary, a practical proposition only to be realised by means of our higher educational system.

[1] From a paper read at the Annual Meeting of the Association of Technical Institutions on March 3.

Any comparison of pre-war British and German chemical ability which attempts to exalt the German as one apart, even as something chemically occult, must take the fact into account that so much of our best intellect as revealed by scholastic agency is absorbed into the civil service that the essence of Britain's research ability has never yet taken part in the industrial competition. In Germany the contrary has obtained. The British chemical mission to Germany after the Armistice found that industry there is systematically linked with the universities, and concluded that if our industries are to succeed in the future it is in this direction probably more than in any other that improvements must be effected.

It must be realised that higher education with respect to science and technology is at the parting of the ways, and whether the future is to emphasise the mediocre and the mechanical or to reveal latent genius will also decide whether the chemical industry, with its quota towards the solution of our unemployment problem, will also take root in this country. Our educational programme, therefore, must include a readjustment of the aims of technical education and the evolution of a new branch of the teaching profession to deal with the higher standard of student attainment necessary. No chemical department should be without a definite and distinct research section in which, at the earliest stage possible, students should be initiated into the methods of scientific inquiry. This was the practice of the great Hofmann, and it is as practicable to-day as it was in his brilliant period. The entire staff should also have service in the research section as part of their duties but with safeguards for individual expression. By this means a network of research colonies will be brought into existence, and the pivotal principle must be insisted upon that directors of research must not be prevented by details of organisation from actual personal participation. A large amount of individual responsibility will thus be generated with a greater resultant effort. As the late Prof. Meldola said, "I have not the least hesitation in declaring the belief that a school of chemistry which is not also a centre of research is bound to degenerate and to become a mere cramming establishment not worth the cost of maintenance." There should also be research centres on the lines of the Emperor William Institutes in Germany, an ideal proposed by Sir David Brewster seventy years ago for providing research careers for worthy men.

I would also suggest that patents should be examined by research organisations, and, where dishonest, the fact broadcasted, so that the intending fraudulent monopolist can be banished from our midst.

Another factor of far-reaching importance to industry is the establishment of English as a language for scientific publications at least co-equal with German. This can be secured on a stable basis only by the quality and quantity of our scientific output.

Only by the development of British research ability can our security as a nation be maintained and our prosperity advanced, since by it a lattice of industries will result, which, by reciprocity with the research agencies, will promote the extension of each. We shall then face the future with the determination to produce results in chemical science not inferior in quality or quantity to those in realms of knowledge where our leadership has never been in dispute.

Physics in Industry at the Wembley Laboratories.

THE General Electric Company, Ltd., is now a very large organisation, which employs some twenty thousand workers. It has engineering works at Birmingham, where it manufactures all kinds of electrical machines. At Stoke, near Coventry, telephones are manufactured. At the Osram lamp works at Hammersmith, lamps and valves of all kinds are made. At Erith, the company took over a few years ago the works of Messrs. Fraser and Chalmers, which manufacture steam turbines and mining plant. At Southampton, electric cables of all kinds are manufactured, and the company has glass works at Lemington-on-Tyne. Mainly on the initiative of Mr. Hugo Hirst, the managing director, it was decided some six years ago to establish a central laboratory to carry out the scientific and industrial researches which are essential for the progress of industry. Mr. Clifford Paterson, who was then the head of the electrotechnical department of the National Physical Laboratory, was appointed superintendent, and he is now helped by a staff of physicists and engineers many of whom have world-wide reputations.

The opening of the research laboratories on February 27 was a very interesting function. Lord Robert Cecil, speaking at the opening ceremony, said that the immediate task of the country is to repair the waste of the war. To do this the first and most essential requirement is to use every endeavour to increase the output of human energy and skill. This can only be done in two ways, namely, by reducing expenditure and by increasing the efficiency of production. Research, by making every man's skill go further, adds to the world's wealth. Science has no territorial boundaries. By promoting research the relations between this country and the world are improved. Sir J. J. Thomson, who also spoke, pointed out that it is absolutely necessary that a research laboratory should have a highly efficient staff. The capacity for the highest kind of research is rare. Training may increase the efficiency of a researcher, but it cannot put insight and originality into him. It is also certain that no research laboratory can guarantee delivery. The output of such a laboratory is always highly irregular and spasmodic. Sir Joseph Thomson also dwelt on the importance of cultivating the thinking powers of the community to the utmost.

The research laboratories are situated near Wembley and have a total floor area of 80,000 square feet, but they have ample room for expansion. The building has a north-light roof and nearly all of it is only one storey in height. The upper floor galleries carry most of the electric cables and the hydraulic pressure, steam, gas, and vacuum pipes required by the experimenters.

These galleries carry the arterial system essential for the laboratory without the necessity for conduits or ducts. This greatly increases the flexibility of the whole system.

The machinery in the central sub-station supplies the electric power, keeps the gases in circulation, and maintains the vacuum in the vacuum pipes throughout the building. Power at a pressure of 2850 volts and on the three-phase system is supplied by the North Metropolitan Electric Supply Co., and is converted into various pressures, both direct and alternating, for the distributing mains by means of motor generators and transformers. The lighting system is permanent, and is not touched for experimental purposes. The method of arranging the experimental distributing system is an extension of that which Mr. Paterson used at the National Physical Laboratory.

In addition to the electric machinery the sub-station contains the vacuum and compressor plant. Two rotary compressors feed into a horizontal boiler placed in the gallery, and this stores the compressed air which is required for experimental purposes. There are also three vacuum pumps driven by motors which are in continuous operation. These exhaust a fine vacuum main to the low pressure of 0·5 mm. of mercury and rough vacuum mains to pressures down to 6 mm. of mercury. There are also high-pressure hydraulic mains, compressed-air mains, and a one-inch hydrogen main.

There are two splendidly equipped workshops, one for metal and one for wood. These make the special apparatus required by the staff. They also engage in research work of their own, devising and improving automatic machinery and suggesting means of accelerating and improving the methods of production.

In the vacuum physics laboratory, X-ray analysis and analyses for detecting traces of gases are made. A novel question that is being investigated is the X-ray danger that may exist in connexion with the use of valve tubes at high voltages. For example, when these tubes are being exhausted, pressures of 10,000 volts and upwards are sometimes applied. Ordinary bulb glass which contains about 18 per cent. of lead is impermeable to these rays, but the special silica tubes often used in valve work are permeable; it is therefore necessary to know whether the work is dangerous or not. The problems produced by the static charges and other high voltage effects produced in bulbs are also being studied.

Some of the laboratories, for example the one for measuring the life of lamps, are used for routine testing. There were 800 lamps undergoing life tests simultaneously. They were of all kinds, carbon filament, metal filament, neon lamps, etc. Some of the neon lamps produce very novel effects and they are in great demand at present in physical laboratories. In photometry the equipment is very complete, and the various problems of illumination are being investigated by most scientific methods. A novel photometer was shown in operation which measured the absorbing power of various surfaces for light. By the use of this instrument the "blackness" of the inside coatings of lamp bulbs tarnished by use can be measured.

A specially novel and interesting feature of the laboratories is that they contain four small experimental factories for making electric lamps, tungsten wire, thermionic valves, and primary batteries, and these laboratory factories are regarded as tools which any of the research staff can use in connexion with the further development of a research. It is inadvisable to specialise research to too great an extent. Lamp research, for example, is not confined to the intensely interesting work on vacuum physics. It is equally concerned with metallurgical research, glass research, radiation from solids and gases, and high tension electrical phenomena in general. In a research laboratory it is necessary that the staff should be interested in practically every kind of research.

Many other interesting researches are being carried out at Wembley, and some of the work done has already proved of great commercial value in the factory. The importance of physics in electrical development may be illustrated by the case of the ordinary switch for the electric lamp. In the old days, an ominous bluish light sometimes made its appearance when the switch was turned off, and occasionally a switch was burnt out. The base of

the switch was sometimes made of wood, which is a very poor insulator. Electricians then improved matters by accelerating the rate at which the terminal pieces separated when the current was broken. Later on it was found that a double air break was a vast improvement, and the base is now made of the best vitreous porcelain, which is practically a non-conductor. Those who use switches nowadays seldom if ever consider the thought that has been expended on their development. Every device in a progressive factory is undergoing continual improvement, and practical men recognise the value of an experimental and theoretical study of the physical laws which govern its development.

The new laboratory at Wembley is one of the largest research laboratories in this country. Compared with American standards, however, it is not large. The research laboratory of the Western Electric Co., Inc., of 463 West Street, New York, has a 13-storey building on a floor area of 400,000 square feet, and employs 1600 full-time researchers under the able guidance of Dr. Jewett, president of the American Institution of Electrical Engineers. The results obtained, however, are seldom in proportion to the size of a research laboratory, and we were much impressed by the ability of the staff at Wembley.

University and Educational Intelligence.

ABERDEEN.—The honorary degree of LL.D. was conferred, *in absentia*, on the Duke of Richmond and Gordon, Chancellor of the University, at a meeting of the Senatus Academicus held on Tuesday, February 27.

Prof. W. Mitchell, vice-chancellor and Hughes professor of philosophy in the University of Adelaide, South Australia, has been appointed Gifford lecturer for the sessions 1924–25 and 1925–26.

CAMBRIDGE.—The Grace approving the regulations for the admission of women students of Girton and Newnham Colleges to titular degrees in the University has now been approved and one stage of a long-drawn-out controversy has been completed. Among the other privileges granted to women students by the new regulations is included the right to be admitted to instruction in the University and to University laboratories and museums, though the number receiving such instruction at any one time is limited to five hundred. Women are now admitted as research students on the same footing as present candidates for the degrees of M.Litt., M.Sc. and Ph.D.

The Right Hon. T. Clifford Allbutt, Gonville and Caius College, Regius professor of physic, has been appointed as delegate to the celebration next June of the 800th anniversary of the foundation of St. Bartholomew's Hospital and the Priory Church of St. Bartholomew the Great.

THE opening of the new chemistry section of the Technical High School of Stockholm is announced in the *Chemiker Zeitung* of February 10. The building cost 3,300,000 kroner, and has four large laboratories for inorganic, organic, technical, and electrochemistry, and a smaller for the study of fermentation. The Director is Prof. W. Palmaer. It is stated that in size the building is exceeded only by that of Boston.

A REPORT on the development of adult education in rural areas has been issued (H.M. Stationery Office, 6*d*.) by the Adult Education Committee constituted in April 1921 by the Board of Education. The report reviews the work in this field of existing organisations—Local Education and other County Authorities, Women's Institutes, University Extension Committees, Workers' Educational Association, Association of Village Clubs, Y.M.C.A., Educational Settlements, and County Unions of village organisations,—the conditions of State aid, and the available sources of supply of books, and concludes with several practical suggestions. Among the opinions formulated by the Committee are: schemes of rural education properly organised can secure immediate and notable success provided village initiative and co-operation are encouraged; some form of county organisation, such as the Oxford Rural Community Council, is essential; national organisation is desirable and has been provided for by the recent establishment of a representative council by the National Council of Social Service; pioneer lectures and short courses of lectures are a necessary prelude to formal classes and merit State aid; the full development of the Carnegie Trust Rural Library Scheme will solve most difficulties as to the supply of books. As regards this last point, it is explained in a highly interesting memorandum appended to the report that it is the policy of the trustees to promote the establishment of county schemes controlled by County Council Education Committees, and 192,000*l*. was set aside by the trustees in February 1920 to enable every county to inaugurate one. By January 1922 thirty-eight were in operation. The key-stone of the whole system is the Central Library for Students (London and Dunfermline), from which any good-class modern book on a serious subject can be obtained through the county librarians.

STATISTICS of 670 Universities, Colleges, and Professional Schools, published by the United States Bureau of Education as Bulletin, 1922, No. 28, shows a total student enrolment for 1919–20 of 521,754, of whom rather more than one-third were women; by departments—preparatory 59,309, collegiate 341,082, graduate 15,612, professional 57,131. Of the 670 institutions, 109 were under public and 561 under private control: 82 were independent professional schools. Of 586 universities and colleges with undergraduate students, 354 were co-educational, and reported 162,558 men and 96,908 women; 117 were maintained exclusively for men and 115 exclusively for women. Enrolments in the professional schools were: law 20,992, medicine 14,242, dentistry 8809, theology 7216, pharmacy 5026, veterinary medicine 908. The percentage of women students ranged between 14 in pharmacy and 0·01 in veterinary medicine. Engineering schools enrolled 51,908 students, almost all men, distributed as follows: general engineering 10,231, civil 8859, mechanical 11,789, electrical 9469, mining 3048, chemical 5743. The number of engineering students more than doubled itself in the decade 1910–20. The total amount of benefactions—excluding government grants—was 65 million dollars. The total income per student—363 dollars in 1920—has risen steadily since 1890, when it was only 68 dollars. During the same period the percentage of receipts derived from the Federal Government, the State, and the city has increased from 12 to 27 and of student fees from 22 to 26, while the percentage from productive funds and private benefactions has decreased from 65 to 38. The following figures relate to universities and university colleges (excluding Oxford and Cambridge) in Great Britain in receipt of annual Treasury grants in 1920–21: income per student 54*l*., percentage of income from endowments 11, parliamentary grants 34, grants from local authorities 9, tuition fees 32.

Societies and Academies.

LONDON.

Royal Society, March 1.—A. **Mallock**: The effect of temperature on some of the properties of steel. The period of torsional vibration and the length of a steel wire were automatically and continuously recorded in terms of time, while the temperature was varied between 15° and 1000° C. The results show (1) that the variation of the rigidity of steel between ordinary temperature and a dull red heat is small (less than 1 per cent.); (2) that above the critical temperature (about 800° C.) the rigidity decreases rapidly; (3) that the temperature coefficient of expansion does not show any marked change as the metal passes through the critical temperature; but (4) that a comparison with the cooling curves of iron and steel proves that the specific heat of the high temperature form of the metal is much less than it is at temperatures below the critical point.—C. H. **Lees**: Inductively coupled low-resistance circuits. The oscillations in each of two circuits of low resistance coupled by their mutual inductance can be simply expressed in terms of a certain product of capacitance and inductance. The expressions for the currents lead to a simple graphical solution of the problem.—Lord **Rayleigh**: Studies of iridescent colour, and the structure producing it.—(1) The colours of potassium chlorate crystals. The structure of the iridescent potassium chlorate crystals investigated by Stokes and the late Lord Rayleigh is examined microscopically. The periodic twinned structure inferred by the latter is clearly shown in the photographs taken under the microscope with polarised light. Some crystals have exceedingly complex structure, showing many groups of evenly spaced twin planes and a very complex reflection spectrum. This results from high interference from twinned layers situated a considerable distance apart. Chlorate crystals, giving a silvery reflection, were obtained by Madan, who heated the ordinary colourless crystals to about 250° C. A complex twinned structure is induced, and photographs of the structure of the crystal and of the reflection spectrum show corresponding irregularities in each, resulting from want of flatness in the twin planes. (2) Mother-of-pearl. The results generally confirm those of Brewster and A. H. Pfund. Micro-photographs show the grating structure of a pearl oyster shell and the structure of parallel layers of an "ear" shell. The absorption spectrum of the latter shows that in agreement with the spacing of the layers the reflection is of the second order. (3) The colours of Labrador felspar. The colours seen by reflection arise from two distinct origins:—(*a*) Specular reflection from tabular inclusions, which show the colours of thin plates and are often 0·2 mm. in dimensions; they are distributed parallel to one of the cleavages. (*b*) Diffuse reflection from a plane about 15° away from the cleavage mentioned; this is the source of the striking colours observed. When the diffuse reflecting plane is examined microscopically under conditions which ensure that the light only comes from a very thin stratum, it is found that the plane of reflection is patchy. The patches are of irregular outline. The diffuse character of the reflection is accounted for by the small diameter of these reflecting surfaces, regarded as independent optical apertures. Their size (0·005 mm.) accounts approximately for the angular diameter of the diffuse image of a point source seen by reflection. The colour of the reflection is not sharply limited to special regions of the spectrum, and can be explained by the interference of streams of light from the two surfaces of each patch. The patches may be fissures in the material, and there is evidence that their thickness is not absolutely uniform. The brightness of the colour is explicable by the large number of reflecting patches adding their effects, without definite phase relation such as would give rise to regular interference.—L. V. **King**: On the complex anisotropic molecule in relation to the dispersion and scattering of light.

Society of Public Analysts, February 7.—Mr. P. A. Ellis Richards, president, in the chair.—E. **Griffiths-Jones**: Titanium in Nile silt. Titanium is determined by a colorimetric method after freeing the sample from silica; 1·3-2·55 per cent. of titanium oxide was found. Egyptian straw showed only 0·4 per cent. of titanium oxide on the ash.—Osman **Jones**: Notes on the examination of preserved meats, etc. The presence of a trace of zinc chloride in the tin container (which sometimes arises through the use of this salt as a soldering flux) causes a more rapid absorption of tin by the food contents; the use of sealing fluid containing a high boiling-point solvent also causes a disagreeable flavour to be imparted to the food material. The absorption of tin by the meat contents of a can is greatest at the time of processing and almost ceases after about 4 months. A dilute solution of iodine in potassium iodide gives a crimson colour with agar, while with gelatin an orange-coloured precipitate is produced.

Optical Society, February 8.—F. W. **Preston**: On the properties of pitch used in working optical glass. Pitch as a material for mounting lenses for polishing possesses many remarkable advantages. Its colour is valuable; the dull black surface in contact with the lens prevents reflection of light at the second face of the glass. Its coefficient of expansion approximates to that of glass, it melts at a relatively low temperature, and remains plastic through a considerable range. Pitch, being an undercooled liquid, may be made sufficiently solid to resist deformation by external pressures during the polishing operation, and yet left sufficiently plastic to yield to internal stresses, so as to be self-annealing at ordinary temperatures. The alteration of properties on prolonged heating is its most serious disadvantage.—T. Y. **Baker**: Prismatic astrolabe designed and made at the Admiralty Research Laboratory, Teddington. This instrument, used for accurate geodetic survey work, is a modification of that designed by MM. Claude and Driencourt, which has been extensively used in Egypt. The modifications are: (i.) The prism can be rotated about an axis parallel to its edges, and the angles of the prism are allowed to depart slightly from 60°; by using each edge of the prism in turn as the front edge, three observations of the star can be made instead of only one, the mean of the measured altitudes being exactly 60°. (ii.) A refracting prism of small angle is mounted to cover one quadrant of the object glass and a duplicate image of one star is thus produced in the field of view. The duplicated images are on the same horizontal level. Observation for contact is made by noting the instant when the descending image is on a level with and between the duplicated images. Laboratory trials show that whereas the mean error of observation with the old scheme was 0·2″, with the new arrangement it is 0·12″.

Aristotelian Society, February 19.—Prof. Wildon Carr in the chair.—C. E. M. **Joad**: The problem of free will in the light of recent developments in philosophy. It is generally admitted that on the basis of the Materialist and Mechanist theories, the

conditions which must be satisfied if free will is possible are not fulfilled, since causation is conceived as proceeding always from the material to the mental. It is not generally recognised, however, that the Vitalist theories, for which the ultimate reality is life or spirit, also preclude the possibility of free will. There are two difficulties in regard to the theory of a vital principle or spirit. (1) How can a homogeneous unity differentiate itself into individual manifestations which are in some sense less real than itself, unless it contains in itself the principle of difference *ab initio*, that is to say, unless it is a plurality and not a unity? (2) Assuming that this difficulty could be surmounted, how can the individuals so formed act, desire, or will with a motive force, other than that derived from the underlying vital principle? If the energy with which they desire is that of the vital principle, and the will with which they suppress the desire, if they do suppress it, is also that of the vital principle, it follows that they are responsible neither for their desires nor for their suppression. These difficulties cannot be solved on the basis of a reality which consists of an initial unity, but the problem of free will, if not actually soluble, takes an entirely different complexion if an initial dualism or pluralism be assumed.

Association of Economic Biologists, February 23.—Prof. E. B. Poulton, president, in the chair.—Sir John **Russell**: Partial sterilisation of soil. The discovery that partial sterilisation increased the bacterial activity of soil was accidental, but when followed up it showed protozoa were present in the soil depressing bacterial numbers. It also showed that certain soil bacteria have the remarkable power of breaking the benzene ring, decomposing such unlikely substances as benzene, toluene, naphthalene, phenol, etc., and utilising them as food. Partial sterilisation kills or reduces disease organisms: here, however, heat is the only certain agent, the various chemical substances having specific properties rendering their general use difficult. A knowledge, however, of disease organisms to be suppressed and of the substances toxic to those organisms, allow the costly heating process to be superseded by the much cheaper chemical treatment. Finally, partial sterilisation produces chemical changes in the soil, some of the products of which have important effects on the plant. Thus, heating soil produces something which stimulates root development. At present partial sterilisation is used by the scientific worker to open up new fields of investigation, and by the practical grower to obtain better crops as the result of the increased bacterial activity, the freedom from disease organisms, and the presence of the root-stimulating substances.—H. G. **Thornton**: The destruction of aromatic antiseptics by soil bacteria. Soil antiseptics fall into two groups: those resembling toluene in mode of action, and those resembling phenol. The second group produces a sudden and great increase in the bacterial numbers in the soil, which is only temporary and is not accompanied by any considerable increase in ammonia production. The effect suggested that organisms fed on this group of compounds. Phenol, cresol, and naphthalene, when added to ordinary manured soil, disappear rapidly, due largely to a biological cause, and bacteria were found which in pure culture were able to derive the energy necessary for growth by decomposing these compounds. These organisms fell into three groups, non-motile resembling *B. phloei*, large rods producing clostridial sporangia, and short oval pseudomonads. The Pseudomonas group is of chief importance in producing phenol destruction in the soil.

PARIS.

Academy of Sciences, February 12.—M. Albin Haller in the chair.—C. **Guichard**: Two triple orthogonal systems which correspond in such a manner that the second tangent of one shall be the polar reciprocal of the third tangent of the other with respect to a linear complex.—A. **Andant**: The application of photography to the study of critical opalescence. The phenomenon was studied by means of a Hilger spectrograph, and the opacity measurements were made with a Fabry and Buisson microphotometer. Curves are given showing the variation of opalescence in ethyl acetate with temperature and with the wave-length.—M. **de Broglie** and J. **Cabrera**: The K absorption spectrum of element 72 (celtium). Some specimens containing zirconium show a feeble band with wave-length $\lambda = 0{\cdot}1905$Å. From corresponding spectra of ytterbium ($N = 70$) and lutecium ($N = 71$) this line would belong to the element of atomic number 72.—Mlle. Irène **Curie**: The distribution of length of the α-rays.—L. J. **Simon**: Viscosity, neutralisation, and isomorphism. The gradual neutralisation of arsenic and phosphoric acids has been followed by viscosity measurements. NaH_2PO_4 is indicated by a well-marked viscosity minimum: Na_3PO_4 shows a viscosity maximum. The arsenate and phosphate viscosity curves are very similar.—H. **Colin** and Mlle. A. **Chaudun**: The diastatic hydrolysis of the glucosides of alcohols. Determination of the molecular weights. An experimental method of fixing the molecular weight of a glucoside by measuring the quantity of enzyme for which the glucose set free from a fixed weight of glucoside no longer increases with the amount of the enzyme. Measurements of propyl, isopropyl, butyl, and isobutyl glucosides are given.—P. **Job**: The complex ions formed by silver salts and aqueous solutions of ethylenediamine.—Marcel **Delépine**: The potassium irido-dipyridino-dioxalates.—Marcel **Godchot**: The 1 : 2 cyclohexanediols and ortho-chloro-cyclohexanol.—Paul **Pascal** and M. **Garnier**: Two definite combinations of nitrogen peroxide and camphor. The melting-point curve of camphor-nitrogen peroxide indicates two definite compounds, $5N_2O_4 + 4C_{10}H_{16}O$ and $2N_2O_4 + 3C_{10}H_{16}O$.—Charles **Baron** and Albert **Verley**: Contribution to the study of a national petrol. Study of the miscibility of alcohol (94-100 per cent.) with ordinary petrol.—F. **Diénert**: Contribution to the study of the circulation of water in the chalk. Results of experiments with fluorescin. Water circulation in the chalk takes place by fissures only and not by filtration. A detailed experimental study of each region is necessary to determine the course of the water underground.—Pierre **Bonnet**: The existences of limestones containing Ural Fusulina in southern Transcaucasia.—Raoul **Blanchard**: The terraces of glacial closing.—Sabba **Stefanescu**: The contraction of the lower maxillary of mastodons and elephants.—Emile F. **Terroine**, A. **Feuerbach**, and E. **Brenckmann**: The unit of energy metabolism and the active mass of organisms.—Albert **Lécaillon**: The tendency to albinism in the hybrids of *Dafila acuta* and *Anas boschas*.—Jules **Amar**: The law of minimum in biology.

Official Publications Received.

Carnegie Institution of Washington. Year Book No. 21, 1922. Pp. xxii+414. (Washington.)

Annual Report of the Director, United States Coast and Geodetic Survey, to the Secretary of Commerce for the Fiscal Year ended June 30, 1922. Pp. iv+148+38 charts. (Washington: Government Printing Office.)

Department of the Interior: United States Geological Survey. Forty-third Annual Report of the Director of the United States Geological Survey to the Secretary of the Interior for the Fiscal Year ended June 30, 1922. Pp. ii+80. (Washington: Government Printing Office.)

Proceedings of the University of Durham Philosophical Society. Vol. 6, Part 4, 1922-1923. (John Theodore Merz Memorial Number.) Pp. 215-290. (Newcastle-on-Tyne.) 2s. 6d.

Report of the Director of the Observatory to the Marine Committee, and Meteorological Results deduced from the Observations taken at the Liverpool Observatory, Bidston, Birkenhead, in the Years 1920-21. (Published by order of the Mersey Docks and Harbour Board.) Pp. 75. (Bidston.)

Diary of Societies.

SATURDAY, MARCH 10.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (4).

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.—Conversazione.

MONDAY, MARCH 12.

VICTORIA INSTITUTE (at 1 Central Buildings, Westminster), at 4.30.—Rev. Prof. A. S. Geden: Value and Purpose of the Study of Comparative Religion.

ROYAL SOCIETY OF MEDICINE (War Section), at 5.—Col. J. F. C. Fuller: Problems of Future Warfare; to be followed by a discussion on The Medical Problems of Future Warfare.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Evolution and Disorders (4) (Hunterian Lectures).

ROYAL SOCIETY OF ARTS, at 8.—J. E. Sears, jun.: Accurate Length Measurement (2) (Cantor Lectures).

SURVEYORS' INSTITUTION, at 8.—C. G. Eve: The Re-valuation for Landlord's Property Tax, Schedule A.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—O. G. S. Crawford: Air Survey and British Archæology.

TUESDAY, MARCH 13.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. C. G. Seligman: Rainmakers and Divine Kings of the Nile Valley (1).

ROYAL SOCIETY OF MEDICINE (Therapeutics and Pharmacology Section), at 4.30.—Prof. F. R. Fraser, Dr. A. N. Drury, Dr. A. E. Clark-Kennedy, and Dr. T. F. Cotton: Discussion on the Action of Quinidine in Cases of Cardiac Disease.

ROYAL SOCIETY OF MEDICINE (General Meeting), at 5.—J. E. Adams: The Urgent Need for Education in the Control of Cancer, to be followed by a discussion by Dr. C. P. Childe, Lord Dawson, Dr. H. Spencer, and others.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. G. Evans: The Nature of Arterio-sclerosis (3) (Goulstonian Lectures).

INSTITUTION OF PETROLEUM TECHNOLOGISTS (Annual General Meeting) (at Royal Society of Arts), at 5.30.—Prof. J. S. S. Brame: Presidental Address.

MINERALOGICAL SOCIETY (at Geological Society of London), at 5.30.—A. Hutchinson: A Graphical Method of correcing Specific Gravity Determinations.—C. E. Tilley: Genesis of Rhombic Pyroxene in Thermal Metamorphism. Mineral Associations and the Phase Rule.—C. S. Garnett: A Peculiar Chlorite-rock from Ible, Derbyshire. The Dissociation of Dolomite.—A. Brammall and H. F. Harwood: The Dartmoor Granite: (*a*) Porphyritic Felspars, and Biotite; (*b*) Andalusite, Sillimanite, Cordierite, and Spinellids.—J. G. C. Leech: Some Occurrences of Titanium Minerals on St. Austell Moor.

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6.—H. Gordon: The Effect of Schooling on Intelligence Tests.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—W. A. Dexter: The Development of the Air Pump for High Vacuum.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Annual General Meeting.

QUEKETT MICROSCOPICAL CLUB, at 7.30.—C. H. Caffyn: Rocks under the Microscope.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Miss M. Edith Durham: "Bird-men" and related Customs in the Balkans.

SOCIOLOGICAL SOCIETY (at Leplay House, 65 Belgrave Road), at 8.15.—J. A. Hobson: Bias in the Social Sciences.

ROYAL SOCIETY OF MEDICINE (Psychiatry Section), at 8.30.—Dr. C. S. Myers: The Association of Psychoneuroses with Mental Deficiency.—Dr. H. J. Norman: Genius and Insanity.

WEDNESDAY, MARCH 14.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Evolution and Disorders (5) (Hunterian Lectures).

GEOLOGICAL SOCIETY OF LONDON, at 5.30.

FELLOWSHIP OF MEDICINE (at Royal Society of Medicine), at 5.30.—A. J. Walton: The Differential Diagnosis of Surgical Dyspepsias.

INSTITUTION OF AUTOMOBILE ENGINEERS, at 7.45.—Major T. G. Tulloch: Multiple-wheel and Track Motor Vehicles.

ROYAL SOCIETY OF ARTS, at 8.—Sir William Warrender Mackenzie: Industrial Arbitration.

THURSDAY, MARCH 15.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lt.-Col. E. A. Strange: Japanese and Chinese Lacquer (1).

ROYAL SOCIETY, at 4.30.—G. C. Steward: Aberration Diffraction Effects.—Lord Rayleigh: Further Observations on the Spectrum of the Night Sky.—Lord Rayleigh: Studies of Iridescent Colour, and the Structure producing it. IV. Iridescent Beetles.—Prof. J. W. Nicholson: Oblate Spheroidal Harmonics and their Applications.—Prof. J. W. Nicholson and Prof. F. J. Cheshire: The Theory and Testing of Right-angled Prisms.—Prof. J. C. McLennan and D. S. Ainslie: The Fluorescence and Channelled Absorption Spectra of Cæsium and other Alkali Elements.—Dr. W. Stiles: The Indicator Method for the Determination of Coefficients of Diffusion in Gels, with special reference to the Diffusion of Chlorides.—H. T. Flint: A Generalised Vector Analysis of Four Dimensions.

LINNEAN SOCIETY OF LONDON, at 5.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. A. J. Hall: Encephalitis Lethargica (Epidemic Encephalitis) (1) (Lumleian Lectures).

ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 5.30.—Prof. B. Melvill Jones: The Control of Aeroplanes at Slow Speeds.

INSTITUTION OF MINING AND METALLURGY (at Geological Society of London), at 5.30—Annual Meeting.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Sir Richard Gregory: The Position and Character of Science in Schools.

INSTITUTION OF ELECTRICAL ENGINEERS AND ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 6.—F. Hooper and J. W. Beauchamp: Co-operation between the Architect and the Electrical Engineer.

CHEMICAL SOCIETY, at 8.—E. H. Usherwood and M. A. Whiteley: The Oxime of Mesoxamide (*Isonitrosomalonamide*) and some Allied Compounds. Part III. Ring Formation in the Tetra-substituted Series.—H. H. Morgan: The Preparation and Stability of Cuprous Nitrate and other Cuprous Salts in the presence of Nitriles.—F. Challenger, A. L. Smith, and F. J. Paton: The Interaction of Hydrogen Sulphide, Thiocyanogen, and Thiocyanic Acid with Unsaturated Compounds.—Prof. T. M. Lowry: The Polarity of Double Bonds.

INSTITUTE OF METALS (London Local Section) (at Institute of Marine Engineers, Inc.), at 8.—W. B. Clarke and others: Discussion on The Heat Treatment of Non-Ferrous Metals.

CAMERA CLUB, at 8.15.—C. P. Crowther: The Man behind the Camera.

FRIDAY, MARCH 16.

ROYAL SOCIETY OF ARTS (Dominions and Colonies and Indian Sections), at 4.30.—Lt.-Col. Sir Leonard Rogers: Recent Advances towards the Solution of the Leprosy Problem.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 5.—Dr. F. M. R. Walshe: The Symptomatology of Eighth Nerve Tumours.—W. Trotter: The Surgical Treatment of Tumours of the Eighth Nerve.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Man's Posture: its Evolution and Disorders (6) (Hunterian Lectures).

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Second Report of the Steam-Nozzles Research Committee.

RADIO SOCIETY OF GREAT BRITAIN (at Institution of Electrical Engineers), at 6.30.—L. F. Fogarty: Accumulators, Dry Cells, and the Currents used in the Reception of Radio Telephony, illustrated by Experiments.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—C. H. Woodfield: Comparative Power Costs.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group Meeting, in conjunction with the Affiliation of Photographic Societies), at 8.—R. H. Lawton: A Criticism of the Prints in the Affiliation Print Competition.

ROYAL SOCIETY OF MEDICINE (Electro-therapeutics Section), at 8.30.—Prof. Gosta Forsell: Some Observations on Movements of Gastro-intestinal Mucosa.

SATURDAY, MARCH 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (5).

PUBLIC LECTURES.

SATURDAY, MARCH 10.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—H. N. Milligan: The Great Sea-serpent.

MONDAY, MARCH 12.

INNER TEMPLE HALL, at 8.—Dr. C. Porter: The Principles and Practice of Sanitary Legislation (Chadwick Lecture).

TUESDAY, MARCH 13.

LONDON SCHOOL OF ECONOMICS, at 5.—Sir Henry Reid: Food Supplies (Statistics, before, during, and after the War) (4).

UNIVERSITY COLLEGE, at 5.15.—Prof. E. T. Whittaker: Electric Fields in Atomic Physics (succeeding Lectures on March 15, 20, and 22).

WEDNESDAY, MARCH 14.

KING'S COLLEGE, at 5.30.—Sir Richard Gregory: The Influence of Science.

THURSDAY, MARCH 15.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 5.—H. S. Goodhart-Rendel: Architecture—a Necessity or a Luxury? (4).

CENTRAL LIBRARY (Fulham Road), at 8.—A. H. Page: Architectural and Record Photography.

FRIDAY, MARCH 16.

UNIVERSITY COLLEGE, at 5.30.—Sir Gregory Foster: Lectures—their Use and Abuse.

CHELSEA POLYTECHNIC, at 8.15.—Prof. A. C. Seward: A Summer in Greenland.

SATURDAY, MARCH 17.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. A. Abram: Travelling in the Middle Ages.

NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

No. 2785, Vol. 111] SATURDAY, MARCH 17, 1923 [Price One Shilling

Registered as a Newspaper at the General Post Office.]

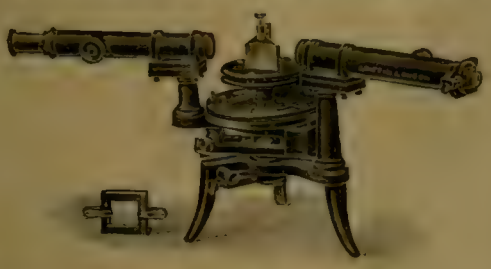
BALANCES & WEIGHTS

SPECTROMETERS



Particulars and Prices on application to—

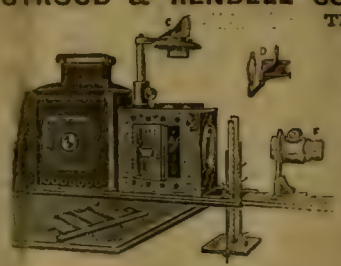
JOHN J. GRIFFIN & SONS, LTD.
Kemble Street, Kingsway,
London, W.C.2.

REYNOLDS & BRANSON, LTD.

Chemical Glassware, Chemical and Physical Apparatus Makers to His Majesty's Government (Home and Overseas Dominions), Laboratory Outfitters, &c.

Gold Medals at Allahabad and London. Grand Prix and Gold Medal at the International Exhibition, Turin.

STROUD & RENDELL SCIENCE LANTERN.



The "University" Lantern, with Russian iron body, sliding baseboard, two superior objectives, with rack and pinion for focussing, condensers 4½ in. diam., plane silvered mirror "A," which is moved by a knob causing the rays to be reflected upwards for the projection of objects in a horizontal plane silvered prism which can be used at "C," or as an erecting prism in mount "D," limelight burner or arc lamp, slide carrier, complete in travelling case, with reversible adjustable stage for supporting apparatus.

PRICE ON APPLICATION.

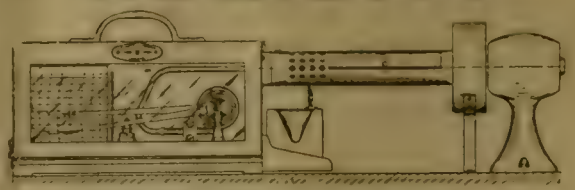
Wireless Apparatus and Accessories supplied.

CATALOGUES (Post Free).

Optical Lanterns and Accessory Apparatus. Chemical Apparatus and Chemicals (New Edition), etc., etc.

14 COMMERCIAL STREET, LEEDS.

HUMIDITY



RECORDING ASSMAN PSYCHROMETER

with Ventilating Fan and Electric Motor.

Write for full particulars.

NEGRETTI & ZAMBRA
38, HOLBORN VIADUCT E.C.1.
LONDON.

BEDFORD COLLEGE FOR WOMEN
(UNIVERSITY OF LONDON).

POST-GRADUATE SCHOLARSHIP.

The Council of Bedford College for Women invite applications for a POST-GRADUATE SCHOLARSHIP in SCIENCE to be awarded in June 1923. Open to graduates of Bedford College only. Value £125 a year for two years.

For further information apply to the SECRETARY, Bedford College, Regent's Park, N.W.1.

BATTERSEA POLYTECHNIC
LONDON, S.W.11

Award of Tate Scholarships for Session 1923-24.

The examinations for the award of SCHOLARSHIPS in ENGINEERING, SCIENCE, and DOMESTIC SCIENCE, will be held on Tuesday, June 5, 1923, and the succeeding days. The scholarships vary in value from £20 to £30 per annum with free tuition, and are tenable for two or three years.

Last day of entry April 21, 1923.

Full particulars on application to the PRINCIPAL.

NATIONAL UNION OF SCIENTIFIC WORKERS.

THE AIM OF THE NATIONAL UNION OF SCIENTIFIC WORKERS is to bring together into one professional organisation all qualified scientific workers, viz. :

Those engaged (*a*) In Higher Educational and Research Institutions.
(*b*) In Industry and Consultative Practice.
(*c*) In State and Municipal Scientific Departments.

Applications for membership are invited from all scientific workers with university degree or equivalent professional qualification. Further particulars may be obtained from

THE GENERAL SECRETARY, N.U.S.W.,
25 Victoria Street, S.W.1.

UNIVERSITY OF BRISTOL.

The University invites applications for the following Grade III. posts which will be vacant on August 1, 1923 :

ASSISTANT LECTURER IN ZOOLOGY
ASSISTANT LECTURER IN CHEMISTRY (ORGANIC)
} Salary £300 per annum.

Applications should be lodged with the REGISTRAR, from whom further particulars are available.

March 3, 1923.

KENT EDUCATION COMMITTEE.
COUNTY SCHOOL FOR BOYS, GILLINGHAM.

The Committee invite applications for the post of HEADMASTER of the above-named School, which will be opened in September 1923. The School will accommodate 200 pupils, but has been planned with a view to future extension to 400. Applicants must be Graduates of a University in the United Kingdom, and must be experienced in Secondary School work.

Salary £600 a year, rising by annual increments of £20 to £700, or by £30 to £850, according to the number of pupils in attendance. This salary will be subject to the usual deduction of 5 per cent for Superannuation, and a further 5 per cent in respect of the voluntary abatement of salaries.

Forms of application, together with Scales of Salaries, Conditions of Appointment and Terms of Service, may be obtained from Mr. R. L. WILLS, District Education Officer, Elm House, 15 New Road Avenue, Chatham, to whom they should be returned not later than March 21, 1923.

March 6, 1923. E. SALTER DAVIES, Director of Education.

THE POLYTECHNIC,
REGENT STREET, W.1.

The Governors will shortly proceed to appoint a HEAD of the DEPARTMENT OF CHEMISTRY. Salary in accordance with the Burnham Scale and resolutions thereon by the London County Council is £600 to £750.

Applications should be made on special form. (Send stamped addressed envelope to the DIRECTOR OF EDUCATION on or before March 20, 1923.)

CHELSEA POLYTECHNIC,
CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.**
Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.**
Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement, Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.**
Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

Telephone : Kensington 809. SIDNEY SKINNER, M.A., Principal.

BATTERSEA POLYTECHNIC,
LONDON, S.W.11.

Principal—ROBERT H. PICKARD, D.Sc., F.R.S.

Head of Chemical Department—J. KENYON, D.Sc., F.I.C.

Day and Evening Courses in Pure Chemistry (Inorganic and Organic) in preparation for University Degrees and A.I.C. and other professional examinations.

Special Technological Courses in Chemical Engineering, Oils, Fats and Waxes, Mineral Oils and Waxes, Toilet Soaps Manufacture, Lubricating Oils and Greases, Paper Making and Paper Testing, Paper Making (Engineering), Commercial Paper Work, Applied Bacteriology, Testing of Disinfectants, Analysis of Foods, Waters, Fertilisers and Feeding Stuffs, Microscopy of Food and Drugs, Flour Milling, etc.

The instruction is both theoretical and practical, fully equipped laboratories being provided.

UNIVERSITY OF LONDON.

The Senate invite applications for the following UNIVERSITY READERSHIPS tenable at Bedford College :

READERSHIP in GEOGRAPHY, salary £700 a year.
READERSHIP in MATHEMATICS, salary £500 a year.

Applications (12 copies) for either post must be received not later than first post on April 13, 1923, by the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7, from whom further particulars may be obtained.

UNIVERSITY OF LONDON.

The Senate invite applications for the RAMSAY MEMORIAL CHAIR of CHEMICAL ENGINEERING tenable at University College. Full particulars may be obtained from the ACADEMIC REGISTRAR, University of London, South Kensington, London, S.W.7.

THE ROYAL TECHNICAL COLLEGE, GLASGOW.

The Governors invite applications for the CHAIR of ELECTRICAL ENGINEERING, from which Professor Magnus Maclean, M.A., D.Sc., LL.D., is about to retire. Salary £1000.

Applications and testimonials should be sent, not later than March 22, to the DIRECTOR of the College, from whom further particulars may be obtained.

PHOTOMICROGRAPHY—1½ in. Holostigmat F/6, by Watson. Perfect Condition, £4 : 10s. List Price, £6. HUNT, 51 Longley Road, Harrow.

ACCURATE CHEMICAL THERMOMETERS.—110° C., 150° C., 250° F., 300° F., 2s. ; 200° C., 2s. 6d. ; 360° C., 400° F. 3s. ; 500° C., gasfilled, special glass, 10s. Beckmann Thermometers with Auxiliary Scale, $\frac{1}{100}$° C., 22s. 6d. each.—CHERLD, Chesham.

OLD PLATINUM, GOLD

Dental Alloy, Scrap, &c.,
Purchased for Cash or Valued.

SPINK & SON, Ltd.,

17 & 18 PICCADILLY, LONDON, W.1.
EST. 1772.

Fine Jewels or Plate also purchased or valued.

NO. 2785, VOL. 111]

A National Water Policy.

THE Minister of Health has recently appointed a Standing Advisory Committee "to confer with representatives of the Ministry on questions of water supply." From a reference in the public announcement of this appointment to the final report of the Water Power Resources Committee of the Board of Trade, it would appear at first sight that the step is the outcome of one of the recommendations put forward by that Committee in its report of November 1921, which was reviewed in NATURE of February 9 last year (vol. 109, p. 161). The proposal therein made, it may be recalled, was for the formation by Act of Parliament of a controlling water commission having jurisdiction over England and Wales, with statutory powers and duties. In commenting on such a far-reaching and momentous proposal, we felt it desirable to deprecate the idea of setting up a fresh department with a retinue of officials and an additional burden of salaries for the taxpayer.

Our first impression, therefore, was one of gratification that apparently the departmental proposition had been dropped and that, in place of it, there was to be a "Standing Committee," presumably honorary, with advisory functions. On further consideration, however, we became less confident that the announcement covered all that it implied, and whether, in fact, it was in any degree a materialisation of the Water Power Committee's findings. Inquiry has confirmed the suspicion that the Ministry of Health is only concerned with the water question as regards supplies for domestic use, and that the terms of reference of the Advisory Committee, though unspecified, cannot possibly be stretched to cover functions which lie within the province of the Board of Trade.

An inspection of the list of the committee shows it to comprise the names of six gentlemen connected with municipal waterworks administration in various official capacities. With one exception, we miss altogether any name which appeared as signatory to the very full and comprehensive report of the Water Power Resources Committee. There is, indeed, a marked absence of that representation of broadly national, scientific, and industrial interests which should, in our opinion, form a prominent, if not a predominant, element in a committee dealing with the policy of development of the water resources of the country.

This is the more disappointing in that, according to the Press, the first meeting of the committee has already been held, and it is announced that it discussed two matters which were in the forefront of the Water Power Resources Committee's recommendations, and have been the subject of earnest

advocacy by NATURE for a number of years past. These are (1) the formulation of the outlines of a national water policy, and (2) the survey of the water resources of England and Wales. We are not in possession of information as to the views of the members of the Advisory Committee on these points, but we conceive that they must have been somewhat seriously handicapped by the absence of assistance from the compilers of the very valuable report to which we have alluded. In regard to the second point, we note that the survey is already in hand, and is being made by the Engineering Department of the Ministry of Health. We confess that we are puzzled by this statement. Conservation and control of water power resources for industrial purposes is not very obviously a question of health, or of physical well-being. We are therefore at a loss for an explanation, unless it be, that the survey is limited to sources of water supply for domestic use. If so, this is not only regrettable as making it an inquiry of inadequate scope, but it is also inconsistent with the announcement that the survey is being prosecuted "on lines recommended by the Water Power Resources Committee in their final report." Turning to that report, we find the recommendation expressed as follows:

"That in view of the importance in the national interest of the utilisation of water power, wherever this is commercially practicable, the Board of Trade, or the Electricity Commissioners, should be charged with the duty of studying, supervising, and promoting the development of all water power. The (Water Power) Department should collect data concerning, and cause surveys to be made of water power resources, and they should give the widest publicity to the results of their inquiries."

Clearly it is not within the province of a Ministry of Health to prosecute such a research, which must lie outside the education and training of its officials. Our own suggestion was that the work might be done as a branch of the Ordnance Survey, as it is done in the United States by the Geological Survey.

A matter of such outstanding importance as national water power control demands the most careful and competent handling. It has been the subject of a searching and painstaking investigation by a committee thoroughly representative in character, the recommendations of which, after several years of exhaustive study and the issue of three reports, were to the effect that the matter did not admit of procrastination or delay, and that it should be dealt with on a generous and effective scale. They were "thoroughly convinced of the necessity of such action if the national water resources are to be properly conserved and fully and systematically utilised for all purposes, and that the work should be proceeded with unremittingly." We therefore urge that the matter should be entrusted to a committee with a scientific and technological element of adequate proportions, and that the survey should be placed in the hands of a department closely associated with this particular class of work.

The Gas Industry.

(1) *The Administration and Finance of Gas Undertakings: with Special Reference to the Gas Regulation Act*, 1920. By G. Evetts. Pp. xi+374. (London: Benn Bros., Ltd., 1922.) 32*s*. 6*d*. net.

(2) *Modern Gasworks Chemistry*. By Dr. G. Weyman. Pp. x+184. (London: Benn Bros., Ltd., 1922.) 25*s*. net.

(3) *Gasworks Recorders: their Construction and Use*. By Dr. L. A. Levy. Pp. xi+246. (London: Benn Bros., Ltd., 1922.) 35*s*. net.

(4) *The Distribution of Gas*. By W. Hole. Fourth edition, rewritten and enlarged. Pp. xv+699. (London: Benn Bros., Ltd., 1921.) 50*s*. net.

THE gas industry had its modest origin in the researches of William Murdoch, the "incomparable mechanic" to whom the Royal Society awarded its Rumford medal for his work in the production and utilisation of illuminating gas. Its rapid growth owes much to the co-operation of the scientific workers, although in the early days, even as now, there were not lacking prominent and distinguished men of science prepared to wail a Jeremiad over the industry. While to-day the nature and magnitude of its operations entitle the gas industry at least to contend for pride of place among applied sciences, whether chemical, mechanical, or physical, it cannot be too strongly emphasised that the industry is the child of pure science, and its present-day problems the problems of pure science. The industry asserts that pure and applied science are one and indivisible.

Scientific literature, apart from technical journals and the Transactions of various institutions, dealing with the fundamentals of the processes and control of manufacture of towns' gas is not at present very extensive. The volumes under review, together with Meade's "Modern Gasworks Practice" in the same series, and Prof. Bone's "Coal and its Scientific Uses," constitute practically the only modern English works dealing specifically with the scientific and other problems of the gas industry.

(1) Consider the magnitude of the industry. We learn from Mr. Evetts's book that in the United Kingdom the public supply of gas is in the hands of about 1630 undertakings. About 20 million tons of coal and 65 million gallons of oil are employed annually in the manufacture of gas in the country. By-products of

carbonisation amount to 10 million tons of coke, 180 million gallons of tar, 170,000 tons of sulphate of ammonia, and 45,000 tons of sulphur annually. About 87 per cent. of street lamps in the country are lit by gas. The annual make of gas is approximately 1200 million therms supplied to consumers through about 8 million meters. The figures are clamant for the maintenance of a due sense of proportion in criticism of the industry. We commend them to the notice of any inclined to regard the gasworks as the original home of the three-card trick, and the gasometer as the present-day residence of the Borgias.

Mr. Evetts has produced an extremely clear and readable account of the legislative and administrative aspects of the gas industry. Primarily intended to meet the requirements of the student, the junior assistant, and others desirous of qualifying for high administrative posts in the industry, the book will be welcomed by a much wider circle of readers.

The provisions of the Gas Regulation Act, 1920, enabling gas to be supplied and sold on the basis of its potential thermal value, are set out in Chapter 2. Although from the date of the publication by the Board of Trade of the brochure on Gas Standards the gas industry generally welcomed the suggested new method of supply (p. 34), it should be remarked that at a somewhat earlier date such suggestions were regarded favourably only by a very small minority of representatives of the gas industry considering the subject. The supply and sale of gas on the only conceivable scientific basis, namely, on a thermal basis, having regard to present-day uses of gas, we owe to the Board of Trade. The electrical unit of energy supply is termed the Board of Trade Unit. We suggest that correspondingly the unit of supply of gaseous energy should be designated the Board of Trade Therm.

Among the matters dealt with by Mr. Evetts are: the sliding scale of gas charges, parliamentary procedure when applying for a Bill, the model Bill, repairs and depreciation, hirings and fittings, arbitration and other workaday matters. Chapter 8, dealing with financial aspects of the sale of gas by therms, is a clear statement of the numerous facts to be taken into consideration before a calorific value is declared. Advocates of the supply of low-grade gas should ponder well the tables on p. 242, giving the costs of mains and the pressures necessary to deliver a definite quantity of energy in the form of gases of various calorific values. In this connexion we may remark that such changes in declared calorific value as have recently occurred have all been in the direction of supplying gas of higher calorific value.

(2) Dr. Weyman's book on modern gasworks chemistry describes the methods employed in the control of plant and processes employed in the manufacture of towns' gas. Chapters are devoted to coal, carbonisation, coke, refractory and insulating materials, tar, ammonia, oxide purification, steam raising, water supply, and lubricants. A great amount of work has gone to the collection of the very large number of analytical and other tests comprised in the volume We regret that frequently these are not sufficiently detailed or clearly described to afford working instructions. Occasionally, and more especially in regard to what would be regarded as essentially physical tests, the descriptions are inaccurate or meaningless. As examples, we would refer to the calorimetric radiation correction (p. 27), the standardisation of the Wanner pyrometer (p. 56), and the determination of thermal conductivity (p. 74). It is certain that the methods described for the determination of the thermal conductivities of materials will not yield results of much value in the hands of the works chemist. This class of work should, we think, for the present, until the gas industry is equipped with its own large central testing establishment, be allocated to the National Physical Laboratory. In any case, if this section of the book is to be retained in later editions, it should include a description of the simpler flow methods, developed at the National Physical Laboratory for the determination of thermal conductivity, and probably more suitable for adoption in industrial laboratories.

(3) Dr. Levy's work on gasworks recorders is the complement of Dr. Weyman's. Control of chemical processes can be based upon the results of snap-tests or the indications of recording devices. There is much to be said for both methods. Painful experience with some recorders forces the present writer to the unfortunate conclusion that generally the former method is to be preferred to the latter. Individual observers suffer from their "personal equations." Recording devices are not without their idiosyncrasies. Their value and trustworthiness are to be determined by the "acid test": How far is the record influenced by, and *only* by, variation in the characteristic to be recorded? Frequently the influence of disturbing factors, such as friction, temperature, and the rest, are completely overlooked in the design of such instruments.

Pressure and vacuum gauges, pyrometers, gravitometers, gas analysis and volume recorders, and densimeters are among the recorders discussed in this volume. The activity, born of the Gas Regulation Act, 1920, among makers of scientific instruments is evidenced by the chapter devoted to recording gas calorimeters. Prof. Boys's instrument, incorporating many novel features and points of geometric design, is worthy of the close attention of scientific instrument makers

generally. Incidentally it may be mentioned that an important feature of this recorder, namely, that the calorific value is recorded in strict relation to the chart ruling, however the chart may be displaced on the drum, is omitted from the description of the chart on p. 127. The electrical flow meter of C. C. Thomas described on p. 208 *et seq.* is finding extensive application in industry, more especially in America. In all descriptions of this instrument with which we are acquainted, it appears to have been overlooked that the device is merely an application of the constant flow method of calorimetry introduced by Prof. Callendar, and is one more in the lengthy and lengthening list of contributions—not always acknowledged—made by pure to applied science. Considering that the platinum resistance thermometer is among the most accurate of all indicating or recording instruments, it is disappointing to find its calibration inaccurately described on p. 62 and the variation of the resistance of platinum with temperature wrongly given in Fig. 56.

The main defect of the present volume is what we may be pardoned for describing as its apparent partisan character. About one-third of the instruments described are the products of a single firm. This is certainly unjustifiable in a work claiming, according to the preface, to describe all recording instruments of utility in gas engineering. We are acquainted with at least five types of recording pyrometers which go unmentioned although they are of utility at least equal to that of any described. Scant justice is done to certain forms of carbon dioxide recorders, to depth gauges, to water or steam meters. The recording specialities of one firm are referred to in the advertisement pages included in the volume but are not found in the text! We register our protest against this growing tendency in English scientific literature of a certain type.

(4) Under the Gas Regulation Act of 1920, the gas undertaking is interested in the supply of gas right up to the point of combustion of the gas in the burner. Mr. Walter Hole, from his experience as superintendent of the City of Leeds Gas Mains and Distribution Department, is, we think, as well qualified as any one within the industry to undertake the task of compiling a standard work on the subject of gas distribution. That a fourth edition of his work has been called for is eloquent testimony that it supplied a need felt in the industry. We would suggest, however, that the subject of gas distribution is so large that a treatise to be adequate must be the result of the co-operation of a number of experts in its various branches. In these days of specialisation it is not to be anticipated that a single individual will be able to deal adequately with, *e.g.*, the jointing of steel mains and the laws of flow of gases in pipes. The result of such an attempt might be foreseen and is evident in the present volume. The section devoted to main-laying is excellent and constitutes the best part of the volume. That devoted to a theoretical discussion of the flow of gases in pipes is inaccurate and altogether inadequate. It would be well, we think, to include the work of Stanton and Pannell and the empirical formula deduced by Lees from their results in this section.

New chapters on inferential meters and gas for industrial purposes have been included. The former is not entirely adequate. The form of Pitot tube developed as the result of work carried out at the National Physical Laboratory is quite incorrectly attributed to Griggs. This error will serve to illustrate the author's apparent general lack of acquaintance with the more strictly scientific aspects of the subjects of gas distribution. The chapter on gas for industrial purposes is wholly commendable and illustrates the great development which has occurred within recent years in this direction, a development very much accelerated by the call for munitions during the War.

Summing up our impressions after carefully reading the four volumes, we would say that the gas industry has at long last started on the way to provide itself with a scientific and technical literature which shall be in some measure adequate to its needs and deserts. The four volumes here briefly reviewed stand in serious need of overhauling, and we suggest that when a further edition of any of the volumes is called for, the proof-reading should be a little more carefully done. Grammatical errors and split infinitives are in some of the volumes almost as thick as "leaves in Vallombrosa," and we are tempted to infer that the gas industry has its own peculiar variant of Kings' English. The prices of the volumes are, even in these days of inflated index figures, exceedingly high. A considerable portion of the text and illustrations in Mr. Hole's and Dr. Levy's volumes is available gratis in the form of trade circulars, and we believe that these circulars will, owing to the high price of issue of the volumes, continue to be the main source of information consulted by the great majority interested in gas distribution and gas-works recorders. J. S. G. THOMAS.

The Earth under the Rule of Man.

Man as a Geological Agent: An Account of His Actions on Inanimate Nature. By Dr. R. L. Sherlock. Pp. 372. (London: H. F. and G. Witherby, 1922.) 20*s.* net.

THE Human period of the Quaternary era has set in. Disregarding epochs of the Pleistocene or of earlier periods in which man has left traces of his

existence, his activity may be said to have begun when a clear field was given for migration. His rule on the earth's surface was assured by the disappearance of continental glaciation from the temperate zones. Henceforward, he began seriously to modify the earth. The improvement of the entrance to a cave was probably his first essay in denudation; the building of a barricade against wild beasts foreshadowed the vast works of transport and accumulation that are traceable in the Pyramids or in Cuzco.

By turning up the soil with pointed sticks, and later with some primitive form of plough, man assisted natural agents in the disintegration of hard rocks. As the soil developed under culture, with a constant renewal of its air-ways and water-ways, the subsoil in humid climates became modified in an opposite direction. Its interstices were choked by fine material washed in from above. There was a greater retention of water in the overlying soil, and acres that at one time were liable to run dry became available for the continuous growth of plants. When a patch became poor and temporarily exhausted, the early and unskilled cultivator moved to some adjacent area, just as the Berber of the Tell, with his camel-plough, or the Bantu in some forest-clearing, with his wooden hoe, is apt to do at the present day. In this way the earth was primarily and profoundly influenced by man. Let us remember that if our "civilisation" comes to us from the crowded life of cities, our "culture" reaches farther back, and was born with the first tillage of the fields.

This widely spread and continuous attack upon the land-surface does not appeal to Dr. Sherlock so much as might have been expected. He is more concerned with the localised and spectacular results of engineering pertinacity in recent centuries. These lend themselves to statistical treatment, and they can be compared with the slowly cumulative effects of natural, that is to say non-human, agents. Dr. Sherlock has brought together a large amount of curious information, and is able to tell us (p. 24) the total output of coal from Great Britain between 1500 and 1913 A.D., the area (p. 110) of England and Wales under pavements in 1908, and the height of the brick structure (p. 236) that forms the famous mound of Babylon. A fine example of his zeal for calculation appears on p. 73, where, by the use of average specific gravities, he records the output of quarries of eleven types of material during nineteen years in cubic yards in place of tons; 2·75, however, seems a slip for 2·25 in the case of gypsum; and is it scientific to use for quarried ironstone a factor so precisely stated as 4·017?

It was well worth while to direct attention to the enormous bulk of the artificial hills of slag or shale that are still growing in our mining areas. The illustrations facing pp. 203 and 207 are convincing evidence of the activity of man. The modification of an area of complex structure by the spread of a city over it is excellently typified in the chapter on London. The story of the origin of Moorfields in water that was banked up against the Roman Wall, and of the replacement of the alluvial mud of the Wall Brook and the Langbourne Water by the subterranean floors of some of our most monumental city buildings, might have been told in even greater detail. Dr. Sherlock, however, is not to be lured into the picturesque. He does not step aside to mention the lining of corridors in modern offices and hotels with the spoils of Egypt and Numidia, with slabs of imperial porphyry, "fiammeggiante come sangue," and with pale marbles voluptuously veined; or the accumulation of exotic blocks, exceeding in variety and length of travel the erratics of an ice-age, which man has brought together to deck, say, San Paolo fuori le Mura, even in an epoch of nineteenth-century restoration. The amount of Caen stone in the south of England, or of the corresponding oolite from Portland in the grey limestone areas of Ireland, suggests similar reflections. A conspicuous example of man's energy in geological transport is to be found in the Portuguese stone that was brought in carracks round the Cape to build the jutting fort on the coral shore at Moçambique.

Though the reader's imagination is not touched by Dr. Sherlock, plenty of facts are given on which to found an outlook. A sense of accurate hard work pervades the volume. The material has been quarried out, and the result of its accumulation is neither a slag-heap nor a cathedral. We have noticed only one misprint ("Berschlag" for "Beyschlag"), and few matters that the geologist could reasonably question. We wish that we could agree with the optimistic statement on p. 112 that "no sooner is a part of the road-covering destroyed than more material is brought from a quarry to replace it." In illustration of the denuding effect of ordinary traffic, a photograph of one of the deeply cut by-ways in the Folkestone Sand of Surrey would have been welcome as a touch of rural England. It would refresh one after reading of the 156,000,000 cubic yards of comminuted quartz-conglomerate on the Rand.

The construction of the volume is such that its main lines suggest attractive by-ways. The amazing transference of rock-material for agricultural purposes from Chile, Christmas Island, or the desert-edge of Gafsa, might well deserve a mention. The destructive action of man-made sulphuric acid in the atmosphere of our industrial towns has been pointed out by Mr. J. A. Howe. Dr. Sherlock, however, has

provided us with ample material for developing the subject along such paths as may appeal to us most nearly. GRENVILLE A. J. COLE.

Comparative Psychology.

Handbuch der vergleichenden Psychologie. Herausgegeben von Gustav Kafka. Band 1: *Die Entwicklungsstufen des Seelenlebens.* Pp. viii+526. Band 2: *Die Funktionen des normalen Seelenlebens.* Pp. viii+513. Band 3: *Die Funktionen des abnormen Seelenlebens.* Pp. viii+515. (München: Ernest Reinhardt, 1922.)

THE present is often said to be a psychological age, and certainly the recent rapid multiplication of psychological books and lectures would seem to justify the above statement. One happy result of the stimulus which popularity has given to the production of psychological literature has been to make that literature extensive and varied. Nevertheless a survey of that literature shows that the psychologist's library is by no means adequate to his needs. There are at least two regrettable deficiencies, deficiencies which are more obvious in English than in German psychological literature. There is, on one hand, no large-size and generally accredited work on theoretical or pure psychology, a work sympathetically mediatory between the several divergent schools of contemporary psychological thought, a work which provides a basis of theory for the co-ordination of the as yet somewhat scattered results reached in the various fields of psychological research. There are in existence many first drafts of and essays towards such a work, but none is detailed and comprehensive enough, apart from the fact that none of them can claim anything like general agreement; and this deficiency, however unavoidable, however much a symptom of scientific health, is obviously very disconcerting to students.

The second deficiency, the one most in question here, is the absence of a sustained and comprehensive attempt to describe the world of living beings from the psychological point of view. Twenty years ago this would have seemed an impossible, if not a thankless task. To-day it is at least possible to make a beginning. For one of the many indications of the psychologicalness (if the word may be permitted) of this age has been and still is the rapid and unresting invasion of one realm after another of concrete experience by the psychologist. From the somewhat supermundane and, to many, jejune science, closely associated with metaphysics, which it was in the last century, psychology has developed into a science which touches practical interests and activities at a thousand points. Education and industry, art and society, war and peace, all have begun to be at least discussed and often treated from the psychological point of view. And one result of this successful ramification has been the accumulation of material for such a description of the world.

What a fascinating gazetteer that would be, a psychological gazetteer of the world! A survey of the world through the eyes and from the vantage point of the psychologist! What tantalising glimpses one has of a psychological description of politics, of business, of courtship and marriage. . . . Those preserves of opinion which, as Mr. Trotter says, are deemed too lofty for knowledge and are reserved for conviction, would no longer be able to keep their sacrosanct aloofness. One would seek to understand not only the origin and persistence of the opinions but also the taboo itself. All phenomena, oaths, and tea-parties, morality and social rank, would be approached from the point of view of psychological interpretation. Ethical and æsthetic prejudgments would neither deter nor mislead, they would be explained. One would psychologise on a cosmic scale, never stopping till the psychology of the psychologist himself had been written.

There is scant prospect, alas, of anything of the quality and scale of the above for a very long time to come. Intensively and extensively contemporary psychology is not equal to such a task. On one hand, psychology, despite its recent advances, has not yet explored, much less cultivated, the full extent of its territory. Progress has been ragged, and while here the workers are many and progress rapid, there it is well if a bare seisin has been taken. On the other hand, psychological theory is as yet too limited and too sketchy, neither strong enough nor comprehensive enough, for the organisation and interpretation of the vast mass of data with which it would have to grapple.

But half a loaf is better than no bread, and if even relative finality cannot be looked for, yet a beginning is feasible. If no beginning has so far been made, with the possible exception of the late Wilhelm Wundt's obsolescent and inadequately conceived "Völkerpsychologie," the fault must lie with the necessary specialisation of contemporary psychology. The individual psychologist has been marooned, as it were, in his own field of work, ample though that field has often been; his tentatives towards communication and co-operation have been baffled by the immensity of the science, and few have had the courage and the vision even briefly and imperfectly to envisage that science as an articulate whole. So that even the little that was possible has been left undone, and the reader who wishes to gain even a cursory and incomplete conspectus of psychological experience must pursue his purpose through scores of ill-related and narrow volumes.

The student's labours have been considerably

lightened, and the present unfortunate and unnecessary state of affairs significantly improved, by a recently published work. This is the "Manual of Comparative Psychology" edited by Prof. Gustav Kafka, of Munich, to which twelve psychologists, including himself, have contributed. The work itself is divided into twelve sections, each section constituting a specific department of psychology and being written by a specialist in that department. These sections are grouped, somewhat unequally, into three groups, each group corresponding to a volume of some five hundred pages. The three groups are: The Evolution of Mind (Animals, Primitive Mankind, and Children); the Functions of the Normal Mind (Language, Religion, Art, Society, and Vocational Psychology); and the Functions of the Abnormal Mind (Psychopathology, Sex, Dreams, and Criminals).

This list sufficiently indicates the scope of the work. It is easy to find omissions: law, industry, and morality are inadequately represented, for example, while the editor himself deplores the absence of a section on the psychology of science, an omission due to his inability to find any one to write the section. It is easy also to find fault with the arrangement of the subject-matter. To mention one point only, it is surely not justifiable to give the impression that sex and dreams are abnormalities. One might again stress the occasional overlapping, the occasional unevenness of treatment and of point of view, and the more than occasional stodginess of manner, due largely to excessive compression on the one hand, and to theoretical incoherence on the other hand. But this is a pioneer work and must be judged leniently. If the reader brings an active and organising mind to its perusal, then the defects will be neutralised and the solid qualities of the work appreciated. For this reason one hesitates to recommend the work to the general reader, above all to the general reader who knows little or no psychology, and to whom an overloaded and viscous style is repellent. To those better versed in psychology its comprehensiveness, its accuracy, and its excellent bibliographies will make their appeal. They will be grateful for the compact account of the psychology of language. They will be glad to have Sante de Sanctis' views on dreams, inasmuch as they are the views of a man who began the study of dreams before Freud published his "Traumdeutung"; and they will be appreciative of and grateful for much else in this timely work. The fact that it is written in German will constitute but one more reason for regret that an international language for science has not long since made the peculiar aptitude of the German for this type of work the common property of mankind.

Our Bookshelf.

Handbuch der Pflanzenanatomie. Herausgegeben von Prof. K. Linsbauer. II. Abteilung, 1 Teil: Thallophyten. Band 6: Bakterien und Strahlenpilze. Von Prof. Dr. Rudolf Lieske. Pp. iv+88. (Berlin: Gebrüder Borntraeger, 1922.) 4*s.* 6*d.*

THE purpose of this handbook, which is to be comprised in a series of monographs by specialists in the various branches of the subject, is to give, in brief compass, a critical presentation of the present state of our knowledge of plant anatomy and cytology. In the volume before us, Prof. Rudolph Lieske, of the University of Heidelberg, has brought together, in a commendably brief and useful form, a critical digest of what is at present known of the morphology of the bacteria and ray-fungi (Actinomycetes). The first part of the book contains an account of the bacteria. In reference to the nuclei and nuclear structures which have been so frequently described, it is concluded that, although there can be no doubt about the existence of minute granules with nuclear characteristics, the presence of true nuclei in the bacteria has by no means been proved. The author has some interesting observations upon the recently described symplastic stage in bacterial development, and on the so-called sexual reproduction of bacteria. Among other topics dealt with are pleomorphism and variability, filtrable viruses, and mycobacteria.

In the second part of the volume the ray-fungi are dealt with. In discussing the systematic position of the group it is pointed out these organisms have certain characteristics in common both with bacteria and fungi, and that they must be looked upon as an independent group standing between the two. The various forms of the Actinomycetes present an astonishing variability both in morphological and physiological peculiarities, and the characters which have been used by various observers to discriminate species are so inconstant that no dependence can be placed upon them.

A literature list accompanies each part of the work, and there is a good index.

Mathematics and Physical Science in Classical Antiquity. By D. C. Macgregor. Translated from the German of J. L. Heiberg. (Chapters in the History of Science, II.). Pp. 110. (London: Oxford University Press, 1922.) 2*s.* 6*d.* net.

THIS volume gives a general survey of the science of classical antiquity, laying special stress on the mathematical and physical aspects. It opens with an account of the Ionian natural philosophy, pointing out that science is the development of early attempts of man to see his way in the world outside. Next there is a chapter on the achievements of the Pythagorean school, followed by two others on the progress made in the fifth century B.C. One of these is on mathematics, still under the influence of Pythagoras, and the other on medicine, which then reached a level not surpassed before the Alexandrian age. The work of Plato and Aristotle is adequately dealt with, while the longest chapter in the book is assigned to Euclid, Archimedes, and the Alexandrian school. In the period of decline which followed (second and first centuries B.C.)

only medicine made any real progress, and a four-page chapter is sufficient to record the work of the Romans. The last chapter, a long one, is devoted to Greek scientific literature of the Byzantine empire, it being stated that the founders of modern science, such as Galileo, Copernicus, and Newton, learnt from the Greeks not only particular results but also the very meaning of science.

Naturally Prof. Heiberg's little book makes no pretence of being a complete history of science in classical antiquity. It puts the achievements of the different schools of thought into a true perspective, and the language throughout is free from technicalities. The book would be improved by the insertion of more dates, even when these are only known approximately. (A companion volume deals more fully with the medical and biological sides of the subject.) W. E. H. B.

Tested Methods of Metallurgical Analysis (Non-Ferrous). By S. Pile and R. Johnston. Pp. 128. (London: H. F. and G. Witherby, 1922.) 7*s.* 6*d.* net.

In referring to the literature of metallurgical analysis the student, and even the worker of experience, frequently finds himself at a loss to select, from the mass of alternative detail offered, a method suited to his immediate requirements. The authors of the present work, while disclaiming any novelty in the methods given, have collected together a series of well-tried methods of which they have had personal experience. The book deals mainly with commercial metals and their more important alloys. It opens with a few introductory remarks on general analytical procedure, and on sampling. In the latter no mention is made of the frequent necessity for rejecting the first few drillings of a bar to avoid the introduction of skin impurities, as distinct, of course, from segregated elements. The suggestion of dissolving up a large quantity of metal, and working on an aliquot portion of the solution, is a good one, and worthy of more general adoption. The metals are dealt with in alphabetical order, several good methods being given for each metal, and special attention is paid to details of manipulation. The inclusion of "moisture" among the determinations is rendered possible by the somewhat "scrappy" reference to fuels and oils. A similar extension in the case of sulphur is treated at greater length. No mention is made of gold or its alloys.

With some exceptions, perhaps of secondary importance, the book is a sound and careful compilation, and should meet all the requirements of those needing, at the working bench, a trustworthy guide to assays coming within the scope of the book, familiar or otherwise.

Faune de France. 4: *Sipunculiens, Échiuriens, Priapuliens.* Par Prof. L. Cuénot. Pp. 31. (Paris: P. Lechevalier, 1922.) 3 francs.

To this excellent series, promoted by a federation of the French natural history societies, Prof. Cuénot, of Nancy, contributes an account of the curious marine animals that used to be classed together as Gephyrea. Nowadays it is supposed that the resemblances between the three groups mentioned in the title are due to convergence, and that each group was derived independently from some primitive ancestor of the annelids. Prof. Cuénot, whose writings of twenty years ago on some of these creatures are well known to zoologists, has here given a clear, interesting, and well-illustrated summary of the species living round the coasts of France. British zoologists, though they have the works of Shipley and the more recent paper by Southern, may none the less welcome this convenient aid to the study of a remarkable assemblage. F. A. B.

Manuel de filature. Par F. Rubigny. (Bibliothèque Professionnelle.) Pp. 366. (Paris: J. B. Baillière et fils, 1922.) 10 francs.

The volume under notice is one of a series of technological works, written primarily for the use of workers in the several industries, and deals with the spinning of all kinds of fibres, including asbestos and artificial silk, and also with the spinning of paper yarn. The treatment follows similar lines to those adopted by other writers on spinning, but with rather more attention to function and less description of machinery details than is the case with English works on the subject. Though this book cannot, any more than similar works on spinning technique, be taken as a trustworthy guide with respect to the raw materials, yet considering the wide field covered in less than 400 octavo pages, the treatment is otherwise remarkably adequate; and the book should be found a useful supplement to the usual works on spinning.

Cours de physique mathématique de la Faculté des Sciences. Par Prof. J. Boussinesq. Compléments au tome 3: Conciliation du véritable déterminisme mécanique avec l'existence de la vie et de la liberté morale. Pp. xlviii+217. (Paris: Gauthier-Villars et Cie, 1922.) 30 francs.

This book is in the nature of a supplement to a complete course of mathematical physics by the University of Paris professor. It contains an extraordinary variety of matter, not very well arranged, but its main purpose is to round off a natural philosophy course by including, or rather by reconciling, the mechanism of physical nature with the indeterminism of life and consciousness. To a certain extent this has been the intellectual problem since Leibniz. Prof. Boussinesq can scarcely be said to claim to bring forward anything distinctively new, but he discusses the problem with full scientific knowledge and keen philosophical interest.

Smith's Intermediate Chemistry. Revised and rewritten by Prof. J. Kendall and E. E. Slosson. Pp. xv+566. (New York: The Century Co.; London: G. Bell and Sons, Ltd., 1922.) 8*s.* 6*d.* net.

There can be no doubt that this book, the first edition of which was reviewed in Nature of October 14, 1920, p. 208, has been greatly improved by revision. It is now more balanced in treatment, is very well printed and bound, and is probably the best elementary treatise on chemistry of the day. The inaccurate historical note on oxygen (p. 28), which was mentioned in the former review, has been toned down, but is still somewhat incorrect. Apart from the very clear and modern account of the chemistry of the common elements, the book contains a large number of brief notes on important matters (vitamins, enzymes, atomic structure, isotopes) not often met with in elementary manuals.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Origin of Radioactive Disintegration.

IN a letter to NATURE of September 16, 1922 (vol. 110, p. 379) R. N. Pease directs attention to the possibility that the radioactivity of the heaviest elements may be due to the disturbing effect of the electrons in the atom. This view may be traced back to the time of the discovery of radioactivity (cf. J. J. Thomson, *Phil. Mag.* 7, 265, 1904, and Lord Kelvin, *Phil. Mag.* 8, 525, 1904). The problem, however, has been seriously complicated by the circumstance that, on the basis of ordinary mechanics and electrodynamics, the outstanding difficulty has not so much been to understand that radioactive disintegration can occur as to understand the simple law of radioactive decay. For the latter question, it seems that the development of the quantum theory has prepared the way to a deeper insight in the sense that the same law may be shown to apply to transition processes between stationary states of quantised systems.

On the basis of the quantum postulates alone it is an open question whether the nuclear instability is a strictly spontaneous process solely dependent upon the state of the nucleus itself, or whether external influences also play an essential part. A tentative argument in favour of the latter view is perhaps afforded by the fact that the life-periods of the elements at the beginning of the disintegration series are very large. This fact suggests the idea that the nuclei may be intrinsically stable and the radioactivity of these elements induced by the action of an external field of force, the origin of which may be looked for in the surrounding electrons. The regular variation in the life-period of successive elements in the disintegration series seems to indicate that the disintegration, when once initiated, proceeds spontaneously until a stable element is reached. On the other hand, the occurrence of radioactivity in the elements of low atomic numbers (rubidium and potassium) might be due to an enhanced efficiency of the perturbations due to some sort of resonance in the interaction between the nuclear and the electronic motion.

The force exerted by the electrons at a point in, or close to, the atomic nucleus will increase rapidly with increasing atomic number on account of the decreasing dimensions of the electronic orbits belonging to a permanent group. It will, however, in addition, depend intimately on the nature of the electronic configuration. If this configuration at every moment exhibits central symmetry, the forces from the electrons will to a large extent neutralise each other. The case is essentially different in the recent theory of Bohr, according to which the electrons belonging to a particular group and moving in eccentric orbits will approach the nucleus in succession. The shortest distance from the nucleus will be attained by the electrons moving in orbits with azimuthal quantum number equal to 1, and will then be given by

$$d = \frac{d_0}{2N}(1 - \alpha^2 N^2) \quad . \quad . \quad . \quad (1)$$

approximately. Here N is atomic number, d_0 the radius of the orbit in the normal hydrogen atom, and $\alpha = \frac{2\pi e^2}{hc} = 7{\cdot}2 \times 10^{-3}$ is the constant occurring in the theory of the fine structure of hydrogen lines. For the uranium atom the above formula gives $d = 15 \times 10^{-12}$ cm. On the other hand, the inferior limit for the diameter of the uranium nucleus, derived from the energy of the α-particles from uranium on assuming this energy to be due to the electrostatic repulsion of the nucleus, comes out of the same order of magnitude as the above value of d. At the moment of closest approach these electrons will thus exert forces upon the individual particles of the nucleus which may be of the same order of magnitude as the electrostatic attraction or repulsion between the particles themselves. For still larger atomic numbers, d will rapidly decrease while the nuclear dimensions will be expected to increase. It is therefore seen that for some atomic number not far ahead of that of uranium the electrons in question would have to pass quite close to the nucleus, and thus exert large perturbing forces on the nuclear particles. For still larger atomic numbers a motion for which the nuclear field is treated as due to a point charge would become impossible as the electrons in question would have to collide with the nucleus. On the whole, it does not appear excluded that the presence of radioactivity among the heaviest known elements as well as the apparent absence of elements of higher atomic numbers may be connected with some sort of interaction between the nuclear and the external electrons.

The efficiency of this interaction will be expected to depend intimately on certain resonance conditions, as is the case for ordinary mechanical systems. The frequencies of the motion of the nucleus must in general be expected to be of an altogether higher order of magnitude than the frequencies in the motion of the electrons; but there remains the possibility that the nucleus as a whole will rotate and this rotational frequency may in some cases be comparable with some electronic frequency. The case when the nucleus rotates with an angular momentum equal to $h/2\pi$ is of special interest, as this value appears to be associated with the most stable state of quantised systems. The rotational frequency w may then be estimated from the expression

$$w = \frac{h}{4\pi^2} \cdot \frac{1}{Ma^2}, \quad . \quad . \quad . \quad (2)$$

where M and a are the nuclear mass and radius of gyration about the axis of rotation. Assuming the nuclear dimensions to increase from about 8×10^{-13} cm. in helium (Rutherford and Chadwick) to about 6×10^{-12} cm. in uranium (cf. above) this frequency is found to decrease from about 10^{20} sec.$^{-1}$ in helium to about 10^{16} sec.$^{-1}$ in uranium. The latter value is essentially larger than the value to be expected for valency electrons. This is also necessary in order to understand the fact that the radioactive properties hitherto on record are independent of chemical combinations. It will further be found compatible with the assumptions regarding the nuclear dimensions to assume the frequencies of nuclear rotation in potassium and rubidium to be of the same order of magnitude as the electronic frequencies of the K and the L electrons respectively in these elements.

The above considerations, however, are to be regarded merely as tentative suggestions, and our knowledge of nuclear structure is probably far too scanty to permit of any definite conclusions concerning these questions at present.

The New Marine Biological Research Station of the Bergen Museum.

FOR close upon one hundred years researches regarding marine fauna have been a prominent part of the work carried out by the Bergen Museum. The first biological station in Norway was built in the year of 1891 and was attached to the museum. On account, however, of the expansion of the city of Bergen, the pollution of the salt-water supply for the station gradually increased to such an extent that the biological work there had to be abandoned.

By the generosity of private donors, who realised that the fine traditions of the maritime research work carried out at Bergen should be maintained, the Trustees of the Bergen Museum have been enabled to build a new station. The biological station (Fig. 1) is now situated on the island of Herdla, about seventeen miles from Bergen. The station is thus right in the centre of one of the richest and most promising fields for research of the west coast of Norway, well known also through the investigations of such British naturalists as Norman, Jeffreys, Harmer, Punnett, and others. The open sea, the deep fjords, and the narrow sounds with their strong currents, offer here the most varied and changing conditions of life for marine fauna, which accordingly is extraordinarily rich and well represented.

FIG. 1.—Marine Biological Station at Herdla, seen from the fjord.

Any biological condition typical of the west coast of Norway may be reached within less than two hours' sail from the station. The salt-water supply is taken from a depth of approximately 25 metres, which guarantees salt water of excellent quality and without appreciable changes in temperature and salinity. Thus are present the best conditions for experimental and embryological research.

The object of the station is to serve as a basis for scientific investigations, as well as for the international courses in marine biology which were held at the Bergen Museum for a number of years until 1914, and with a large participation from abroad. The station is open to naturalists of all nations. During the period in the summer when no courses are held, the station has tables for ten scientific workers besides the staff. During the winter there are tables for five only. Being situated close to the open sea, which never freezes, the station can be kept open all the year round, and thus offers good opportunities for collecting material during the winter months. The station contains the necessary accommodation for housing naturalists visiting it.

A 25-ton research vessel, the *Herman Friele*, is attached to the station, and is equipped with appliances for research down to a depth of 1500 metres. Moreover, the station is provided with a smaller open motor boat and various rowing-boats.

By the opening up of this new station, facilities are afforded for utilising again the particularly favourable conditions for marine biological investigation offered by the west coast of Norway. I shall be glad to reply to any inquiries regarding the station or the reservation of tables.

A. BRINKMANN.

Museet, Bergen, Norway.

Industrial Applications of the Microscope.

WHILE one reads with satisfaction in NATURE of February 17, p. 239, of the ever-increasing examples of the application of the microscope to industry, the fact remains that the use of the mineralogical microscope with the small amount of knowledge of crystal optics necessary has up to the present been practically disregarded.

In 1918 a considerable amount of work was done in this connexion dealing particularly with explosives, but the results were never published, and hence it is thought that the following example may be of interest.

It was proved quite definitely at the Ardeer Factory of Nobel's Explosives Company that the degree of nitration in guncotton and nitrocellulose could be ascertained directly by the optical properties of the product. Thus it was found that the birefringence of ordinary cotton fibre before nitration was strong and of a positive character. The same cotton after being fully nitrated showed strong birefringence but of a *negative* character, while cotton with an intermediate degree of nitration was shown to be practically isotropic.

It was found afterwards that a corresponding work had been carried out by Dr. Phil Hans Ambron in Germany, and he published a table giving the actual values and character of the birefringence of nitrated cellulose and also nitrated ramie or China grass. It is, of course, true that the degree of nitration can be obtained quicker and more accurately by means of a nitrometer, but the two lots of information differ widely. The nitrometer gives the average nitration of the whole sample while the microscope gives the actual nitration of separate fibres, and is therefore a valuable test of the homogeneity of the sample.

During the War, when acetone was unobtainable, a substitute had to be found as a solvent for nitrated cellulose in the making of cordite. Ether-alcohol was the substitute used. Now, while cellulose and almost any form of nitrated cellulose are soluble in acetone, ether-alcohol will only dissolve nitrated cellulose of a certain percentage nitration, and the homogeneous nitration of large samples of cotton was

by no means easy or altogether certain, and hence the microscopic method should have been invaluable. The results of these experiments were obtained too late to be used on a large scale, but they certainly show an example of the class of information obtainable.

Another application of a rather humorous nature can also be cited. A large consignment arrived in the factory of what was called ground silica. This was sent to the analytical department and its percentage of silica ascertained. It was pointed out, however, that the value of ground silica did not lie in the purity of the material but in its fineness and homogeneity. This was tested both by elutriation and the microscope. The microscope revealed the fact that the material was nothing but an inferior sand, with very little grinding. Ground silica must, of course, always show conchoidal fracture and not rounded grains. This sample was also shown to contain the mineral glauconite actually replacing the tests in small fragments of foraminifera, and hence had during its formation been closely connected with the sea. The price per ton indicated that the material was supposed to have been obtained by the grinding of vein quartz.

The identification of asbestos has been published before, but it bears repeating. Platinised asbestos was extensively used in the sulphuric acid plant. The asbestos was originally supplied from the continent, but during the war this supply was not available. The South African asbestos or the mineral crocidolite was used as a substitute with very disastrous results. It was decided, therefore, that the nature of the original asbestos must be obtained by chemical analysis and all samples similarly tested. The chemical analysis of a complicated silicate like asbestos is a long and by no means easy process, as the asbestos is seldom free from other complicated silicates. Now, it was found by a very simple mineralogical test that the original sample was the mineral chrysotile, and by similar tests it was quite easy to ascertain which of the other samples was also chrysotile and to pick out the purest. In this way, a dozen samples were tested in two hours, whereas the chemical analysis had already been in hand for three months, and was likely at the same rate to take another six and give no information whatever.

The simple test for chrysotile was mounting it on a microscopic slide in mononitrobenzene and rotating it between crossed nicols. The refractive index was obtained by the Becke method. The refractive index together with the birefringence and optical character render the mineral quite distinct from any other sold as asbestos. These are three of the very many occasions that cropped up so frequently.

Marlborough College, Wilts.

Factors of Odorous Strength.

IN the letter from Mr. J. H. Kenneth published in NATURE of February 3, page 151, a relation is indicated between the odours of certain substances and specific gravity. If, however, we examine the boiling-points of the odorous constituents of the four oils mentioned, we find that in order of increasing vapour pressure the oils stand as follows: sandalwood (305), cedarwood (280), origanum (230), and terebene (160), the figures in brackets being the approximate boiling points. This order is precisely that represented by the specific gravity quoted by Mr. Kenneth.

I scarcely think the phenomenon with which Mr. Kenneth's letter deals, can safely be ascribed to the specific gravity of the oils, although possibly in this instance the specific gravity is a property concomitant with volatility. Volatility alone, however, does not afford a completely satisfactory explanation of this and many other phenomena connected with the smell of an odoriferous substance. There are at least four factors concerned, namely: (1) Volatility; (2) solubility in the aqueous layers in the nose; (3) solubility in the lipoid fats of the nose, and (4) chemical reaction with osmoceptors in the nose.

A substance which fails to satisfy any one or more of these factors is odourless, and it is obvious that variations in the factors will produce variations in both the strength and the quality of the odour.

T. H. DURRANS.

The Dyson Perrins Laboratory,
South Parks Road,
Oxford, February 6.

WITH reference to Mr. Kenneth's letter in NATURE of February 3, p. 151, I should like to point out that, if the "votes" be counted on a sort of proportional representation scheme by adding to the first votes for each substance half the second, a third of the third, and a quarter of the fourth, we get the following results in votes:

S.	C.	O.	T.
18·66	11·56	9·33	6·33

This result seems to me to enforce Mr. Kenneth's argument.

The Life-Cycle of the Eel in Relation to Wegener's Hypothesis.

IN NATURE of January 27, p. 131, under the title "The Distribution of Life in the Southern Hemisphere, and its Bearing on Wegener's Hypothesis," an account is given of a discussion at a recent meeting of the Royal Society of South Africa on this question. Opinions were divided, the geologists suspending judgment, while the hypothesis was opposed on botanical and entomological grounds as being unnecessary. On the other hand, it was said that the most important zoological evidence in support of Wegener's theory was provided by the distribution of the isopod, Phreatoicus.

It seems to me that strong evidence in favour of Wegener's hypothesis is to be found in the life-history of the European freshwater eel, as revealed by the brilliant researches of Dr. J. Schmidt, of Copenhagen. For something like eighteen years Dr. Schmidt has been engaged on this subject. He has published numerous papers and has summarised his results in the Philosophical Transactions, published a year ago, and quite lately in NATURE (January 13). It will be sufficient for the present purpose to allude only to certain of his results.

Of the two freshwater eels of the North Atlantic, the American species spawns somewhat to the south and west of the spawning region of the European species, and the larvæ attain full size and, after metamorphosis, enter the freshwaters of the American coast when about one year old. On the other hand, the larvæ of the European species, originating more to the east but still in the same region, are transported by the Atlantic Drift and its continuations, aided perhaps by their own efforts, it may be for thousands of miles, as shown in the chart, p. 51 of the article in NATURE of January 13. Still more to the point, the larvæ are about three years old when they become transformed into elvers and enter

freshwaters. A larval life so extremely prolonged, as Dr. Schmidt points out, is quite unique. The rate of growth, moreover, is extraordinarily slow. At full size, after about three years' growth, the larvæ are approximately three inches long, although the temperature of the water in which they are immersed is comparatively high. In our own waters with much lower temperatures most young fishes would attain a corresponding length in as many months. The extremely slow growth of the larvæ of the European eel is thus an adaptation to the prolonged journey.

It is scarcely possible to understand this unique phase in the life cycle of the European eel on the hypothesis that the geographical conditions were formerly the same as now exist. But if Wegener's theory be accepted, the explanation is simple. As the coasts slowly receded from one another the larval life of what became the European species was more and more prolonged by natural selection in correspondence with the greater distance to be traversed. T. WEMYSS FULTON.

The Stoat's Winter Pelage.

SIR HERBERT MAXWELL'S letter on the above in NATURE of February 17, p. 220, raises points of great interest. Presumably if his glacial explanation be correct, stoats taken from the Scottish Highlands to the south of England will still become white in the winter; whereas stoats brought from the southern counties to the north of Britain will remain the same colour the year round. Has this ever been put to the test?

It would be instructive to know whether winter coats intermediate in shade between brown and cream-white are ever assumed. I ask this from the point of view of mutation, which is so much to the fore at present. Have, for example, circumpolar white animals arisen from coloured ones through chance albinos being preserved and increased by Mendelian segregation, or have they appeared through the selection of paler and paler forms leading eventually up to white?

Then again, taking Sir Herbert Maxwell's explanation as correct, have we not here an example revealing how slowly evolution may work? The elimination of the arctic winter garb of the stoat in Britain is not yet complete, though some thousands of years at least must have elapsed since the last ice age.

One more point: Is the British stoat as regards its pelage reverting to the pre-glacial condition, and if so, how does this harmonise with the view that evolution is irreversible? JOHN PARKIN.

The Gill, Brayton, Cumberland.

SIR HERBERT MAXWELL'S attractive thesis (NATURE, February 17, p. 220), that latitude and not winter temperature regulates the seasonal change of the stoat's pelage from brown to white, does not meet all the facts of the case. Islay is farther north than Monreith, and yet in Islay a large proportion of the stoats retain their summer colour throughout the winter.

Having made arrangements some time ago to obtain specimens of the Islay stoat, regarded by Mr. Gerrit Miller as a distinct race, I was struck by the fact that individuals killed in December and February were in summer coat. This suggested inquiry as to the usual course of events in the island, and Mr. Macdonald reported that there white winter stoats are rather the exception than the rule: that of more than 20 stoats he had killed during the winter of 1921–22, only one was entirely white, although in the previous winter the proportion was higher, about six being white; but that only in exceptional years did the proportion of white individuals attain to about half of the total number killed.

Now the latitude of Edinburgh is not far off that of Islay, yet my impression is that here almost all the stoats become white in a normal winter.

These and other facts strengthen the old idea that climate is somehow involved in the colour-change, which seems also to depend to some extent on the condition of the individual animal.

JAMES RITCHIE.

The Royal Scottish Museum,
Edinburgh, February 21.

SIR HERBERT MAXWELL, in NATURE of February 17, p. 220, directed attention to what he considered the conditions determining the winter change of colour in stoats, and inferred that the tendency to undergo such a change is usually the inherited characteristic of some particular strain or breed, rather than the outcome of any special present local severity of climate. He said the effect was most marked in the Highlands of Scotland and diminished regularly as one travelled south, until on reaching Cornwall the winter blanching seemed almost entirely in abeyance.

Since his observations appear to be confined to the island of Great Britain, Sir Herbert may be interested to learn that as a boy at Jersey, about the year 1880, I happened to come across a white stoat. This was shot by a neighbour, in St. Lawrence valley, and, after being stuffed, kept by us for some years. It represented a perfect ermine, the fur being pure white except for a black tail. I never heard of, or saw, any other specimen in Jersey, either white or brown. The case seems interesting, for the stoat belonged to a breed which must have been free from any extraneous admixture, particularly from the north, since that remote period in the past, when the French coast (on which the Channel Islands are situated) was finally separated from Great Britain by the English Channel. Further, the climate being mild and uniform, the tendency to assume a winter pelage can only have resulted from very ancient inheritance.

The Subject Index to Periodicals.

MAY I add a few words of information to the appreciative review of the above publication which appeared in NATURE of February 17, p. 214. Our headings are "The Subject Headings used in the Dictionary Catalogues of the Library of Congress" to which an annual supplement is published. These are linked up with the corresponding classes in the shelf-classification of that library. The advantage of this type of catalogue is that, if properly compiled, it combines system and uniformity with the property of immediate reference. It is in fact a class catalogue in which the headings are arranged in "index" order. Your reviewer's suggestion that we should print a list of the journals indexed in each Class List will be certainly adopted when our funds admit of it. Our Class Lists for 1915-16 contained such Lists as well as Authors' Indexes, and it was with the utmost regret that we were compelled to discontinue these features.

The following extract from an official letter now being circulated widely throughout the British Empire may interest some of your readers:

"In assuming responsibility for the Index the Council of the Library Association was actuated by the following considerations:

"(1) That, in view of the rapid growth of the periodical press, the analytical indexing of periodicals could be carried out with due regard to efficiency and economy only by co-operative effort.

"(2) That such co-operative publication should be controlled by a British professional body rather than be left to the enterprise of a foreign publisher.

"(3) That the Index should be compiled by trained library workers on a voluntary basis, and that the price should be fixed as nearly as possible to the cost of production, and without any idea of profit."

Every effort will now be made to bring the Subject Index up to date. We hope to complete the 1920 Class Lists this summer and commence the publication of the 1921 Lists in the autumn. For further particulars application should be made to the Hon. Secretary of the Library Association, Westminster Public Libraries, Buckingham Palace Road, S. W.

E. W. HULME,
Editor of "The Subject Index to Periodicals."

Time Relations in a Dream.

I HAVE read with much interest Dr. Atkin's letter in NATURE of January 27, and also Mr. Barcroft's letter in the issue of October 23, 1919 (vol. 104, p. 154) to which he refers. My own observations, made in various degrees of semi-consciousness, appear to show that there is no such thing as a definite time relation, as it depends entirely on the degree of consciousness, the time scale being enormously shortened in the semi-conscious state most remote from wakefulness, so that the images produced by the mind must succeed one another with extraordinary rapidity when in that state. As wakefulness increases, the time scale seems to expand, and the succession of events proceeds more and more slowly, until it practically stops or becomes normal as wakefulness resumes absolute control. I have been led to believe that the mind is *always* active—just like the heart always pulsates—whether we are asleep or awake, and that control and memory are the features of our waking condition, so that we do not remember the images it calls forth, except when we are beginning to awaken, and the degree of activity of our memory in our dreams and the extent of the dream memorised merely depend on the rapidity with which we reach wakefulness.

I have made a number of observations of hypnopompic pictures, or optical illusions, which occur while sinking into slumber or during gradual awakening. I described my first observations in the Journal of the Society for Psychical Research for April 22, 1921, but since then I made several curious observations, some of which concern the case in point.

The hypnopompic pictures which I have observed are generally landscapes passing *slowly* before one's closed eyes, when in an *almost awake* condition, one being fully aware of one's wakefulness, and having one's full reasoning powers *while the illusion proceeds*, so that one can make precise observations and experiments as to the effect of volition, etc. The pictures, which are extraordinarily sharp and full of detail, appear as an endless panoramic band or film passing *slowly* before one's mind's eye, so to speak. The film may pass in any direction, right to left, or the reverse, or vertically downwards, or obliquely. A film may snap, but it invariably slows down as consciousness increases, till it becomes motionless and *then* gradually fades.

It seems as if several such bands or films could exist at the same time, passing one in front of the other, and sometimes in different directions, the uppermost alone being visible of course, and its sudden ending by snapping allowing the one underneath to be visible. This would explain the sudden changes which are often noticed in dreams. The fact that the film is panoramic (and not cinematographic, that is, without perception of translation) is remarkable, as one would have expected it to be cinematographic in character. Once, attaining consciousness very rapidly, I glimpsed, for a couple of seconds, a blurred mass of lines such as one sees from an express train on a wall quite close to the track—lines caused by the persistence of vision of the details on the wall, combined with their motion relatively to the train. I have no doubt whatever that I had witnessed the hypnopompic "film" nearly at its normal speed, but with a mind already "slowed down" by the return to consciousness, and unable to cope with its speed and see the details which otherwise I am persuaded—by the agreement of all my observations—would have been visible.

The latter observation bears directly on the question of duration. At such a high translation speed, hundreds of times faster than the usual speeds I had hitherto observed, a whole panoramic view must pass in an extraordinarily short time. Moreover, at such a speed, cinematographic effects are possible, but I fail altogether to imagine by what mechanism they could take place, and so far my observations have given me no clue, although I have once or twice witnessed variations in the process which prevent me from despairing of getting further insight into this mysterious working of our minds. It seems as if control and memory slowed down the working of the mind so that the speed of succession of the images is an inverse function of the degree of wakefulness.

The Social Influence of Science.

IN his article in NATURE of February 17, p. 209, Mr. F. S. Marvin says: "When in the sixteenth century the mind of Ancient Greece awoke again . . ." The advent of modern science is here considered as a revival and continuation of Greek knowledge; an opinion very commonly held, but entailing some difficulty—a millenary period of stagnation and even retrogression. This is inconceivable; the very essence of science is progress, continuous but not steady, because the rate is increasing. This characteristic of science was pointed out in the Harveian Oration for 1897 by Sir William Roberts ("Science and Modern Civilisation," NATURE, October 28, 1897, vol. 56, p. 621).

Antiquity has been artistic, literary, philosophical with deductive reasoning; but is markedly deficient in the objective study of Nature and the inductive mentality. The philosophers' knowledge of things was part of their system, based on *a priori* principles. Their opinions were many and conflicting, with various degrees of credulity, a few of them by chance right. The influence, if any, on the birth and growth of modern science has been very limited; the method of working, by patient observation and experimenting, is exactly the reverse. The rise of the experimental inductive method was like a botanical mutation and inaugurated a new era in the evolution of mankind.

AD. K.

Antwerp, February 17.

It is true that progress was made in certain directions during the "millenary period of stagnation," for example, the improvements in mathematics due to the Arabs. Yet the main fact in the re-birth of science in the sixteenth century is the discovery of the work of the Greeks, especially in geometry, astronomy, and geography. Descartes goes back to Pappus, Copernicus to Aristarchus, Toscanelli to Ptolemy. There is no question that in the general spirit with which the medieval mind regarded Nature there was retrogression, and that the Greek mind did come to life again at the Renascence, partly in its broader quality of rational inquiry, partly in the actual works of Greek thinkers.

F. S. MARVIN.

German Book Prices.

In reference to Prof. Browning's letter in NATURE of December 23 (vol. 110, p. 845), I should like to point out an added difficulty in India and Burma. Not only are exorbitant prices charged for German books, but to the majority of our students such books are useless owing to their ignorance of the language. The Indian or Burmese student already has to learn English in order to study chemistry, and to ask him to learn German as well is too great a handicap and should be unnecessary.

The appearance of certain recent works on inorganic chemistry shows that British chemists are capable of compiling exhaustive treatises, and a dictionary of organic chemistry in English would be invaluable. The Society of Dyers and Colourists is preparing a colour index, and the combined strength of the Chemical Society and Institute of Chemistry should be able to produce a work on organic chemistry which would enable Indian or Burmese students to carry out research in organic chemistry without constant reference to German works.

Single Crystals of Aluminium and other Metals.

The brilliant account given by Mr. G. I. Taylor at the Royal Society (February 22) of the deformation of single crystals of aluminium leads me to direct attention to work done in this laboratory ten years ago by Mr. B. B. Baker and Dr. E. N. da C. Andrade. Mr. Baker showed that sodium and also potassium cylinders when stretched contracted laterally so as to lead to an approximately elliptical section, and when they broke they did so at a chisel edge. The surfaces are marked with a double set of slip lines. A photograph of the appearance is shown in the Proceedings of the Physical Society of London for 1913.

Dr. Andrade, who was experimenting at the same time on the traction of metals, showed that similar results were obtainable with tin and lead, and also with frozen mercury (*Phil. Mag.* 1914). He concludes that they are due to large uniform crystals of a size comparable with the diameter of the rod. From the regularity of behaviour over a length of several centimetres it may be concluded that both were dealing with single crystals several centimetres long in the case of each of these materials—at any rate in the same sense as that in which the crystals of aluminium are spoken of as being single.

The crystals of sodium are still in my possession, having been carefully preserved in anhydrous paraffin. They show the characteristics, even the fine surface markings, practically as well as when they were drawn.

Paradoxical Rainfall Data.

At Blue Hill careful measurements of rainfall have been made for thirty-seven years. There is no break in the record and the amounts are checked by more than one gauge. Data for the entire period 1886–1922 are given in Blue Hill Meteorological Observations. The average monthly values are:

January	101·1 mm.	July	104·1 mm.
February	101·0 ,,	August	100·8 ,,
March	109·2 ,,	September	103·1 ,,
April	94·1 ,,	October	96·4 ,,
May	94·0 ,,	November	97·7 ,,
June	86·3 ,,	December	97·9 ,,

Year . . . . 1185·7 mm.
Month . . . 98·8 mm.

The driest month is June and the wettest is March. Yet the driest month in the whole period was March 1915, when the total rainfall was only 1 mm. What is equally remarkable, the wettest month was June 1922, when 274 mm. fell. It is difficult to explain these rainfalls on any theory of probability. The June rainfall was not due to abnormally heavy showers.

Atmospherics.

Many who have "listened in" must have been much interested by the peculiar sounds the telephone generally emits, in addition to those produced by the waves from the broadcasting station. Although atmospherics are produced by the electric discharges during thunderstorms, many would appear to have a very different origin.

In the discussion of a paper on "The Study of Radio-telegraphic Atmospherics in Relation to Meteorology," by C. J. P. Cave and R. A. Watson Watt (Journal of Meteorological Society, January 1923, pp. 35-42), Mr. L. F. Richardson asked Mr. Watson Watt "if he could explain the origin of the peculiar atmospherics which were experienced at Eskdalemuir on the telephone, which was connected with an overhead wire in a lonely valley. In addition to the ordinary clicks there was a 'swishing' sound. The frequency of the vibration diminished as the swish went on. This property was characteristic of the sound of a shell passing high overhead. Mr. Richardson had the idea, perhaps a mad one, that the swish might be produced by a meteorite."

Many of the atmospherics I have heard have had this character, and it may be suggested that the idea that they are produced by very small meteorites is not quite such a mad view as would at first appear.

In the higher atmosphere, there may be a very considerable electric potential gradient, and if a meteorite, entering it, ionised a path in it, an electric discharge might occur along this ionised path sufficiently strong to give off electric waves. There is indeed reason to suppose that the direction from which the waves come is influenced by variations in the sun's position (R. A. Watson Watt, Proc. Roy. Soc., vol. 102, 1923, p. 460).

Recent Aeronautic Investigations and the Aeroplane Industry.[1]

By Prof. JOSEPH S. AMES, The Johns Hopkins University, U.S.A.

FEW industries offer better illustrations than the manufacture of aeroplanes of the intimate relation between purely scientific investigations and the practical application of their results. As an example of this fact, attention may be directed to three experimental researches in progress at the laboratories and flying-station of the National Advisory Committee for Aeronautics at Langley Field, Virginia. These researches were begun and are being conducted in order to add to our knowledge of the science of aeronautics, but their results are of the utmost importance to the industry and also to the art of aviation. Other illustrations might well have been selected, but these are, in many respects, of "actual" importance.

The first research deals with the pressure distribution over the wings, tail-surfaces, etc., of an aeroplane —an old problem, studied with marked success by the staffs of the British establishments at Teddington and Farnborough. What is novel in the present investigation is the extension of the problem to aeroplanes making manœuvres, and to wings of different plan form, varying the angle of attack and the aileron angle. The method adopted is simple: numerous series of small openings are made in the surface to be investigated; each of these is joined by a rubber tube to a capsule containing a metal diaphragm, to which is attached a tilting mirror; a beam of light is reflected from this on to a photographic film which may be shifted, thus permitting a series of observations to be made. The apparatus in use records the pressures existing at sixty points simultaneously. All the diaphragms are, of course, standardised and calibrated. (In the case of wind-tunnel experiments a number of liquid manometers are used.)

Among the questions already investigated are: the change in pressure distribution produced by a loop, a roll, etc.; the effect of the shape of the wing-tip, square corners, elliptical, raked off, etc.; the influence of the air-stream from the propeller. In all cases the pressures are measured quantitatively, and the results are shown in two ways: by making plaster or wooden models, like a relief map; and by drawing contour lines of pressure (Figs. 1 and 2). From the knowledge thus obtained, the aeroplane engineer can decide upon the best shape of wing or elevator, etc., and upon the relative strength required in different parts of his structure; and further, if a breaking sand-load test is thought necessary, he can so distribute the load as to make it correspond to actual flying conditions.

Plan and elevation showing contour lines and built-up model.

FIG. 2.

The second research was undertaken to learn the actual motion of an aeroplane in alighting, taking off, making oscillations and manœuvring, and at the same time to record the motions of the control surfaces and the forces exerted by the pilot (Fig. 3). A large number of instruments are required, all of which were newly designed with special reference to lightness and compactness, as well as to accuracy. The central instrument is a photographic film wrapped on a cylinder which is in rotation, for all records are made upon this by beams of light reflected from mirrors which form part of all the various instruments. When in actual use on an aeroplane, the pilot simply presses one button at the beginning of a manœuvre, and this starts everything. The instruments in use at the present time are as follows:

(*a*) Chronometer, consisting of a constant speed

[1] Substance of a lecture delivered before the Franklin Institute, Philadelphia, on November 23, 1922.

motor, properly governed. Lines of light are recorded at definite intervals, *e.g.* two seconds.

(*b*) Air-speed recorder, simply a Pitot-Venturi nozzle attached to suitable pressure-recording capsules.

(*c*) Single component accelerometer, consisting in the main of a damped steel spring, one end of which is free.

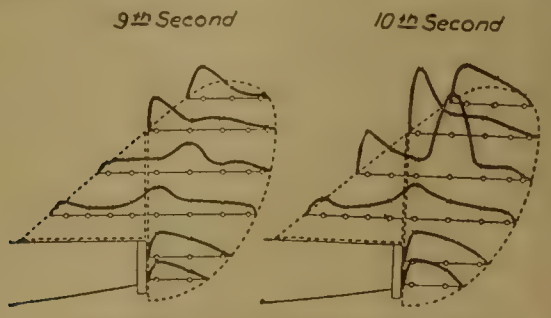

FIG. 3.—Showing the curves of pressure on the entire surface of the rudder at various intervals during a left turn.

(*d*) Three-component accelerometer, a combination of three of the previous instruments. The sensitiveness of the three is adjusted corresponding to the amount of the acceleration to be expected.

(*e*) Angular velocity recorder, making use of a high speed electric motor as a gyroscope. The curves obtained by this give, when integrated, angular displacement, and when differentiated, angular acceleration.

(*f*) Three-component angular velocity recorder, a combination of three of the previous instruments.

(*g*) Control position recorder, consisting essentially of three spring-controlled spools threaded on an axial screw, each spool actuated by a wire leading to the horn of the control surface.

(*h*) Force recorder, using a carbon pile resistance method.

Of course all these instruments are not used at the same time, but only as many as are needed for the study of each particular question.

From a practical point of view these instruments allow the performance of an aeroplane to be recorded accurately, in a manner quite free from the personal impressions of the test-pilot; and, further, the records taken in any manœuvre tell a story which is perfectly plain. Numerous questions, often raised by pilots, have already been answered, and pupil pilots have received great assistance.

The last research to be mentioned is one which is only beginning, but the apparatus has been carefully tested, and a few preliminary readings have been made. This refers to a new method of investigating the "scale effect." In the ordinary wind tunnel the forces and moments on a model of about one-twentieth the full scale are observed, and from these measurements deductions are made as to the promised performance of the full-sized aeroplane, or part thereof. It has been known for many years that in order for these deductions to be justified it would be necessary to have in the tunnel and in the flight of the actual aeroplane the same Reynolds's number, as it is called. This number is the fraction $\rho VL/\mu$, in which ρ is the density of the air, V is the relative velocity of the air-stream, L is a linear dimension of the aeroplane (or part), and μ is the coefficient of viscosity. It is clear that the Reynolds's number in the tunnel is about one-twentieth, or less, that of the aeroplane in flight. To obviate this, a complete wind tunnel has been installed inside an elongated steel tank—35 feet long, 15 feet in diameter—in which the air is kept compressed to 20 or 30 atmospheres (Fig. 4). The walls of the tunnel proper are hollow, and in this space the balances are installed, so as to be out of the air-stream. The attitude of the model in the tunnel may be varied, and the balancing weights may be shifted, etc., by small electric motors, controlled from outside the tank. Readings consist in viewing through suitable small windows a number of Veeder counters. The importance of this apparatus from the point of view of aerodynamics is sufficiently obvious, and from that of the aeroplane designer even more so.

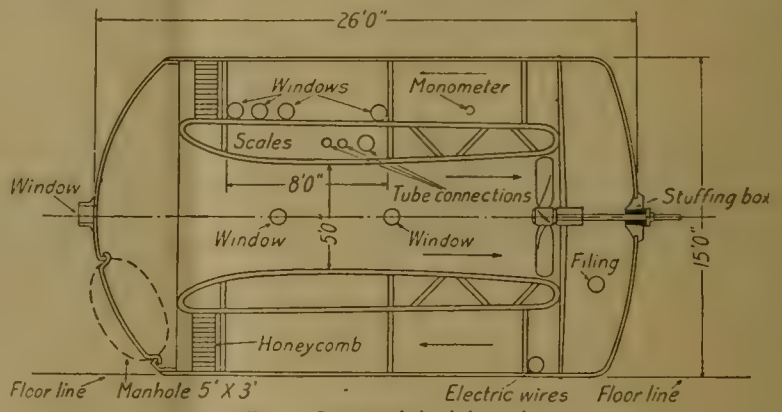

FIG. 4.—Compressed air wind-tunnel.

Radiography and Physics.[1]

By Dr. G. W. C. KAYE.

THE frail, untrustworthy X-ray tube of 1895 and the more robust and dependable tube of the present day do not differ in principle. The X-ray tube still remains a device for generating high-velocity electrons and suddenly depriving them of that velocity by hurtling them against a target. In fact, the tube possesses all the characteristics of a battlefield, except that as yet we lack the ability to give our shells speeds of the order of 50,000 miles a second. Then, just as a flash of flame accompanies the sudden stopping of the shell, so do the X-rays set out in all directions from the target, travelling in straight lines just as

[1] Abstracted from the opening address to the Society of Radiographers, October 31, 1922.

light rays radiate from a lamp. The X-ray tube is, indeed, an X-ray lamp in which the applied voltage is analogous to the temperature of a luminous lamp. If we raise the temperature of the latter, we shorten the average wave-length; so with the X-ray bulb, if we raise the voltage the average wave-length is diminished.

In the light of present-day knowledge, what do we know to be the factors which control output from an X-ray tube? The radiographer is concerned more with the general or continuous spectrum of X-rays than with the superposed rays characteristic of the target. In regard to the former the factors are three: (*a*) The number of the cathode rays or electrons which strike the target; (*b*) the speed of the electrons; (*c*) the massiveness of the atom of the target. (*a*) is represented by the current through the tube, (*b*) by the voltage across the tube, (*c*) by the atomic weight or, more precisely, the atomic number of the metal of the target.

To what extent do these several features come in? To settle these points let us call in the aid of the X-ray spectrometer and vary each of the factors one by one. The spectrometer spreads out into a continuous fan of rays all the various wave-lengths present, and tells us, moreover, the amount or intensity of each wave-length. So that if we plot wave-length against intensity, we get a curve which clearly reveals the composition of the beam. Furthermore, the area of the curve is a measure of the output. If we do this, we find that the several spectral curves show that the X-ray output is proportional to the current, to the atomic number of the target, and to the square of the voltage.

We notice that the voltage comes in as a second-power term, and the importance of measuring voltage by the radiographer not sporadically but as a routine procedure day in and day out should be stressed. For the applied voltage has a dual importance: it not only dominantly affects the output, but it is the sole arbiter of quality or penetrability or wave-length.

The time is approaching when we must gradually relinquish the use of the terms "hard" and "soft" X-rays and accustom ourselves to speak of wave-lengths. For example, in deep therapy we can say that the spectrum of rays employed lies between 0·06 and 0·2 Å.U., the mean effective wave-length being about 0·15 Å.U. or less. The radiographer who uses point spark-gaps up to, say, 6 inches long employs a spectrum of rays ranging from about 0·12 to 0·4 Å.U., the mean effective wave-length generally lying between 0·2 and 0·3 according to the filter and nature of the high potential generator. We might make a beginning by agreeing, for example, that "hard" rays refer to rays with wave-lengths shorter than 0·1 Å.U., and that "soft" rays have wave-lengths longer than 0·3 Å.U., the intervening rays being of "medium" hardness.

Let us consider the career of an electron in an X-ray tube impelled towards the target with a velocity which it owes to the applied voltage V. The chances that that electron will ultimately come into suitable conflict with one or more atoms in the target and so generate X-rays are slight—about 1000 to 1. The energy of the electron is, in fact, much more likely to be frittered away as heat. Assuming that the unlikely happens, one of two things may occur: the electron may lose all its energy at one encounter or it may do so by instalments in a succession of encounters. In other words, if we agree to think of its energy in terms of the original driving voltage (V), then it may lose the whole of V in one step or do so in a number of steps.

Now Planck's quantum relation tells us that whenever an electron has its speed altered the wave-length of the X-ray produced is inversely proportional to the energy given up by the electron; that is, to the equivalent loss of propelling voltage. It will be noted that no question arises of the nature of the target. To put it another way:

$$\begin{pmatrix}\text{Loss of propelling}\\ \text{voltage on electron}\end{pmatrix} \times \begin{pmatrix}\text{Wave-length of}\\ \text{resulting X-ray}\end{pmatrix} = \text{const.}$$

In those encounters where the whole of the energy of the electron is transferred in one fell swoop, the shortest-waved X-rays possible to that voltage will be generated. They will be accompanied by a variety of longer waves depending on the varied experience of other electrons, but always a short-waved limit is set by the magnitude of the full exciting voltage.

We are led to appreciate a number of other results. It is seen at once why we do not get (as was once imagined) homogeneous X-rays when a tube is excited by constant potential, and where all the electrons reach the target with the same velocity. Nevertheless, we should expect that the proportion of short waves would be greater with constant potential than it would be with fluctuating potential, the peak value of which is equal to that of the constant potential. Furthermore, from what is known of the effect of voltage on output, we should anticipate a greater X-ray output (and less heating of the target) with a constant voltage than when that voltage is diluted with lower voltages. Both these surmises as to the superior efficacy of constant potential are confirmed by the X-ray spectrometer.

With reference to the existence of a minimum wave-length or boundary to every spectrum of general X-rays, this is fully borne out by spectrometer measurements and photographs. Numerically, Planck's relation becomes:

$$\begin{pmatrix}\text{Minimum wave-}\\ \text{length in Å.U.}\end{pmatrix} \times \begin{pmatrix}\text{Maximum}\\ \text{voltage}\end{pmatrix} = 12{,}350.$$

This very simple relation provides us with a scale of quality which, if not perfect, is more exact than any which the radiologist has been in the habit of using. If we glance at typical spectral curves of X-ray emission, we see that they are not symmetrical—the centre of gravity of the curve is well towards the quantum limit—the shortest waves are the dominating ones, and still more so if the rays are subjected to normal type filtering. The mean effective wave-length of a spectrum of rays is seen to approximate to the wave-length of the peak of the curve; that is, the wave-length of maximum intensity. Now, there is some evidence that the "peak" wave-length is proportional to the limiting or quantum wave-length, and this fact enables us so to identify very fairly the quality of a mixed bundle of X-rays. No doubt something depends on the wave-form of the exciting potential, but the

effect of this is probably less important as the voltage is raised. The precision of the method would be enhanced if steps were taken to standardise apparatus and technique, so that all work could be done by the use of, say, three or four spectra the distinctive features of which, including energy distribution, could be determined and specified.

Among the other interesting aspects of the X-ray tube is the distribution of the rays in different directions from the target. With the usual 45° target the rays are most intense at right angles to the cathode ray beam. For radiographical purposes it is often better to mount the target face more nearly at right angles to the cathode beam and thus employ a pencil of rays which leaves the target face at a relatively small angle. The width of the focal spot is thus foreshortened and definition enhanced.

If penetrating power is the important factor, then we may well endeavour to utilise the X-rays leaving the tube in the direction of the cathode rays, which X-rays are of appreciably shorter wave-length than in other directions. Thus a tube in which the target also served as a metal window would offer advantages on this score.

The proper choice of filter may do much to increase the effectiveness of a tube. For example, it is known that, weight for weight, silver is relatively more transparent than lead to short waves, but is relatively less transparent to longer waves. Again, copper is relatively superior to aluminium in letting through short waves, but relatively inferior as a filter if long waves are required.

What has the future in store for us as regards X-ray tubes? Higher voltages are coming—one hears rumours of 500,000 volt tubes in Germany; and both the United States and Germany have, I understand, developed transformers giving 1 million volts. The life of 200,000 volt tubes is none too long; there will be many difficulties to overcome before a 500,000 volt tube will become a practical proposition.

A crying need is more robustness in the X-ray tube, which must become more of an engineering job. The portable Coolidge tube with lead-glass walls ¼ inch thick and a window of soda-glass for letting out the rays is to be commended on this score. Equally robust is the new miniature dental tube of similar design which measures only 4 to 5 inches long and has a diameter of about 1½ inch. It is operated at 45,000 volts and 10 milliamperes, is mounted in the same oil-tank as the transformer, and gives excellent definition. It also contributes substantially to the protection which the radiographer has a right to demand. In this connexion we may confidently look forward to a time at no very distant date when, in the interests of the operator, all protective material and apparatus shall be certified by the National Physical Laboratory. This will be realised when I mention that different makes of lead-glass on the market differ by 100 per cent. in protective value. The same remark applies to lead-rubber.

What should be our ideal in radiography? To make the process as simple and noiseless as taking an ordinary photograph. The patient should hear nothing untoward, the apparatus should look no more formidable than a camera. Spark and brush discharges should be taboo; the rumble of rotating machinery anathema. Standardised technique must be the order of the day for much of the radiographer's work. The number of variables must be cut down.

It is possible that the future may witness the fuller development of the metal X-ray bulb of a design radically different from the present. Much work is being done on them at the present time. But in almost every section of a radiographer's X-ray equipment there is room for great improvement. How low the efficiency is may be gathered from the following. We may take it that the efficiency of the high-tension generator is of the order of 50 per cent., that of the X-ray bulb 1/1000. We may assume that half the rays emitted by the bulb are utilised, that half these useful rays are arrested by the object, and that 1 per cent. of the remainder is recorded by the photographic plate or screen (rather more, say 5 per cent., if an intensifying screen is used). Thus the overall efficiency of an X-ray equipment is of the order of 1 in 800,000.

An Inquiry into Dog Distemper.

FOR some considerable time it has been felt in this country that an investigation might be undertaken with advantage on the mystery of dog distemper, and the matter has recently been brought to a head by an appeal from the editor of the *Field* to dog lovers. A considerable sum of money has been promised, and the Medical Research Council has undertaken to organise an experimental inquiry with a view of finding out the causal agent of the disease and possibly a prophylactic. As announced in NATURE of March 10, a committee has been appointed under the chairmanship of Sir William Leishman, the other members being J. B. Buxton, S. R. Douglas, F. Hobday, and C. J. Martin. Other workers, it is suggested, will be co-opted for special investigations later on.

Distemper is an acute highly contagious disease, presenting symptoms somewhat analogous to measles in man. While some have regarded it as specific for the dog, others consider that it occurs in cats, young foxes, wolves, jackals, hyænas, and even monkeys. From its contagiosity it is certain that the cause is a microbe of some kind, which, however, has hitherto remained unmasked. Indeed, there is very little real scientific knowledge extant on the disease. This is in part, at any rate, due to the fact that what veterinary surgeons and the laity call distemper is almost certainly not one but several different diseases. That one of these is the specific disease distemper is, however, very probable.

At present the concept of "distemper" is entirely clinical. Thus, one finds descriptions in the literature of catarrhal, gastric, nervous, and exanthematic types of the disease. There is a great body of evidence to show that one attack of the malady confers a durable immunity on the survivor. The disease occurs in all countries and was apparently known in antiquity. On the other hand, there is a tradition—it is little more—

that distemper was introduced into Europe from South America in the seventeenth century. There have been many researches on the probable cause, and from the time of Semmer (1875) down to the present, every known type of microbe has been incriminated, many authors with great assertiveness having maintained that they had found the specific micro-organism.

Many have believed that Carré came nearest the truth with the idea that the *causa morbi* is an invisible microbe which can traverse bacterial filters. With filtrates obtained from nasal secretions he obtained lethal effects which were claimed to be identical with true distemper, and he regarded the visible bacteria found by others as of the nature of secondary invaders, which obtained a hold on the tissues as a result of the depressing effect of the real filter-passing virus.

This view is largely accepted without criticism, and is said to be the line along which the new committee will work. It may be pointed out, however, that Carré's work, which is not given in any great detail, has been adversely criticised by Galli-Valerio, and especially by Kreganow, who worked under the direction of Frosch, himself a known and successful worker on the filter-passer of foot-and-mouth disease. Filter-passers have been suggested or proved for a number of pathological conditions, notably the mosaic disease of tobacco plants, foot-and-mouth disease, Cape horse sickness, fowl plague, molluscum contagiosum, etc. These filter-passers have much in common. They are highly infectious, invisible, filterable, and non-cultivable. The causes probably constitute a new group of living things, which, if discovered in the case of distemper, may throw a flood of light on many unknown causes of disease in man, and it is for this reason that the work now being undertaken on distemper will be watched with unusual interest. W. B.

Obituary.

PROF. E. E. BARNARD.

IT may safely be said that the whole astronomical world is mourning the death of Edward Emerson Barnard, which occurred on February 6, and very many will feel it as the loss of a personal friend even more acutely than as the removal of one of the world's most remarkable observers.

Prof. Barnard was born at Nashville, Tennessee, on December 16, 1857; he was left fatherless and destitute by the Civil War, and had to go out to work in a photographic studio in Nashville at the age of nine, after the most meagre opportunities of education. But his subsequent career is a remarkable proof of the adage that "where there is a will there is a way." He worked most faithfully for his employers, and at the same time devoted his evenings to private study; it was not till the age of nineteen that his attention was directed to astronomy by perusal of Dr. Dick's "Practical Astronomer." The next year he had saved enough to buy a 5-inch telescope, with which in 1881 and 1882 he discovered the first two of his large family of Comets.

In 1883 Prof. Barnard obtained a fellowship in astronomy at Vanderbilt University, which gave him the opportunity for perfecting his education and the use of a 6-inch equatorial, with which he did useful work on comets, nebulæ, and double stars.

In 1888 Prof. Barnard went to the Lick Observatory, where he had the advantages of a giant telescope and a splendid climate. Three years later he made the sensational discovery of the fifth satellite of Jupiter, the first addition to the retinue of that satellite since the days of Galileo. In 1889 he had observed an eclipse of Japetus by Saturn and the ring which gave important information on the transparency of different parts of the crêpe ring. He was also doing very useful photographic work, photographing the Galaxy and the tails of comets with the Willard lens. These photographs showed interesting detail, in particular the shattered tail of Brooks's Comet of 1893. He demonstrated the value of a lantern lens for depicting faint diffused nebulosity; in particular, he discovered a huge nebula with many wisps that wandered over the greater part of Orion, the former "great nebula" of which was but a pigmy compared with it. Besides discovering very many new comets, he was frequently first in the field in detecting periodic ones on their return; for example, Pons-Winnecke in April 1921, the position of which had only been roughly predicted. In 1896 he left the Lick Observatory for the Yerkes Observatory, but the change involved no real break in his work.

Prof. Barnard took up a new and fruitful line of work in recent years, making a minute study of the light changes of all the Novæ that have appeared in modern times. Many of them had become excessively faint and difficult objects, but he was able to prove that some of them were still varying in a more or less regular manner.

Mention should also be made of Barnard's discovery of the star of largest known proper motion; this was no mere accident, but a well-earned fruit of careful study of numerous photographs.

Prof. Barnard was both a fellow and an associate of the Royal Astronomical Society, and was awarded its gold medal in February 1897.

It is pleasant to record that Prof. M. Wolf named two of his minor planet discoveries Barnardiana and Rhoda after Barnard and his late wife. It is a testimony to the universal sentiments of affection and esteem that were felt towards them.

A. C. D. CROMMELIN.

PROF. J. RADCLIFFE.

PROF. JOSEPH RADCLIFFE, head of the department of Municipal and Sanitary Engineering in the Municipal College of Technology, Manchester, died on February 16 at his residence in Crumpsall after a brief illness, at the age of sixty-six years.

A native of Rochdale, Prof. Radcliffe was forced by circumstances to commence to earn his own living at a very early age, but managed to attend evening classes with such success that he was one of the first scholarship students sent by the Rochdale Pioneers' Co-operative Society to the then Owens College at Manchester. After serving an engineering apprenticeship in Rochdale, he passed into the Waterworks department, where he gained a special experience, which led to his later

appointment as engineer to the Todmorden waterworks. In 1891 he commenced his career as professor in the Manchester College of Technology, where he had previously devoted untiring energies to founding the department by holding evening classes. In 1906, the Victoria University of Manchester conferred on him the degree of M.Sc.Tech.; and practically all the institutions and societies interested in his subjects had recognised his great abilities.

It is no exaggeration to say that the death of Prof. Radcliffe will be sincerely mourned all over the globe by former students, the numbers of which must literally run into thousands. Apart from his sound teaching, his wonderful kindness and modest, genial disposition have made his one of the most regretted losses his college and profession have ever sustained.

Mr. T. W. Stratford-Andrews.

Mr. T. W. Stratford-Andrews, who died on February 17, was a director of many companies connected with electrical industries. He was born in 1870 and educated at King's College, London, and his practical training in engineering was obtained at the works of Siemens, Schuckert, in Berlin.

Mr. Stratford-Andrews succeeded his father as managing director of the Indo-European telegraph line in 1899, but before assuming his new duties he took part in the expedition which went 800 miles up the river Amazon to lay an extension of the Western Brazilian telegraph cable. In 1897 also he rode on horseback through Russia and across the Caucasus to Teheran to inspect the route of the Indo-European land line. This journey he described in a little book entitled "Overland to Persia." In 1913 he covered the same ground again in a motor car accompanied by his wife and his sister. He was decorated by the Shah of Persia for his services, and received the thanks of the Russian Government.

Mr. Stratford-Andrews was the first to introduce direct automatic Wheatstone working on the Indo-European system. He also initiated, in conjunction with Sir Henry Kirk of the Indo-European (Government) department, direct operation at high speed between London and Karachi, a distance of 5600 miles. In his later years he took the greatest interest in radio-telegraphy and telephony, and he was chairman of the Radio Communication Company. His wide knowledge and technical insight were much appreciated by his numerous colleagues.

Prof. Ignaz Vogel.

The death occurred on December 29 last of Prof. Ignaz Vogel, a well-known agricultural bacteriologist and mineralogist. He was born on April 15, 1871, at Altenkunnstadt in Franconia, and after studying chemistry under Emil Fischer at Würzburg he graduated in 1893. Taking up physiological and bacteriological research work, he became assistant to Prof. Dunbar at Hamburg, where he remained till 1900. He was then appointed to the position of bacteriologist at the agricultural experimental station of Posen, being transferred five years later to the Emperor William Institute at Bromberg. In 1914 he was called to Leipzig as director of the bacteriological department of the Agricultural Institute of the University of Leipzig, where he succeeded Prof. Löhnis, who had received an appointment as agricultural expert in the United States.

Prof. Vogel published at Marburg a number of researches on the occurrence and the transformation of the various kinds of sugar in the bodies of plants and animals, most of which appeared in the *Zeitschrift für Biologie*. Later he turned his attention to the study of the bacteria of the soil, and of solid and liquid manure. He published numerous papers concerning the fixation of atmospheric nitrogen in the form of ammonia, and the transformation of this substance into nitrates and albumen, most of which appeared in the *Zentralblatt für Bakteriologie*. In the "Handbuch der Milchwirtschaft" he edited the agricultural section.

The researches of Vogel have contributed greatly to the increase of agricultural production by showing how the various methods of manuring can be properly adjusted to the qualities of the soil. In his university work he trained a number of able pupils, being always willing to communicate his great knowledge to his colleagues. All those who have been able to enjoy his teaching and society greatly regret the loss that agricultural science has suffered through his premature decease.

Prof. A. N. Favaro.

On September 30 of last year, there passed away at Padua, Antonio Nobile Favaro, widely known for his numerous contributions to the history of mathematics and physics. Born at Padua on May 21, 1847, educated at the University of Padua and at the engineering schools at Turin and Zurich, he entered in 1875 upon his long career as professor of projective geometry at Padua. His "Lezioni di statica grafica" (1877) were soon after translated into French. So early as 1873 he began the study of the history of science by a contribution on the evolution of planimeters. For nearly half a century he worked assiduously on questions dealing with the history of mathematical instruments, with papers and letters of Tycho Brahe, N. Tartaglia, Leonardo da Vinci, and others.

The researches for which Favaro is best known, and which mark the crowning effort of his long career, are on the life and work of Galileo and his friends. In 1887, Favaro received a commission from the Italian Government to edit the complete works of Galileo. He devoted nearly thirty years to this task and brought out the "Edizione Nazionale" of Galileo's works in twenty volumes, which serves as a model to other governments as to what can and should be done in editing the works of great men of science. As by-products Favaro brought out a series of publications, "Amici e corrispondenti di Galileo Galilei," consisting of more than forty parts and constituting an important contribution to our knowledge of science in Italy during the sixteenth and seventeenth centuries.

Florian Cajori.

We regret to announce the following deaths:

Dr. Norman Dalton, senior physician to King's College Hospital and formerly professor of pathological anatomy in King's College, London, on March 9, aged sixty-five.

Prof. J. D. Van der Waals, professor of theoretical physics in the University of Amsterdam, on March 8, aged eighty-five.

Current Topics and Events.

IT is fitting that some reference should be made in these columns to the fact that it was just fifty years ago that Mr. Edward Clodd, the veteran scientific thinker, happily still with us, published his first book, "The Childhood of the World." In 1920, at the advanced age of eighty, he published his "Magic in Names." In the period which elapsed between the appearance of these two books, Mr. Clodd devoted the leisure of a busy life of affairs to scientific research in branches of study connected with the physical and mental evolution of man. The results were embodied in a number of volumes dealing with various aspects of this central problem, of which the principal are: "The Childhood of Religion," 1875; "Myths and Dreams," 1885; "The Story of Creation," 1888; "The Story of Primitive Man," 1895; "A Primer of Evolution," 1895; "Tom Tit Tot," 1898, perhaps his best known and most enduring work; "The Story of the Alphabet," 1900; and "Animism," in 1906. In addition he produced monographs on his friends and associates—Bates, of Amazon fame, Grant Allen (1900), Huxley (1902), and a volume of "Memories" published in 1916. Mr. Clodd was one of a band of workers, of whom Huxley and Tylor were the best known, and who now, unfortunately, have nearly all passed away. To their untiring efforts to promote and popularise anthropology, its present position as a serious branch of scientific study is almost entirely due. Those of a younger generation who were first introduced to the evolutionary point of view in the study of man and of his religion and mental concepts through the lucid exposition and power of logical demonstration of which Mr. Clodd is a master, owe to him a debt of gratitude which is not likely to be forgotten.

FURTHER details of the progress of excavations at the Temple of the Moon God at Ur of the Chaldees, to which reference was made in these columns last week (see p. 336), are now to hand. Information given in a telegram published in the *Times* of March 7 indicates the relation of the present discoveries to those made by Dr. Hall in the course of his investigations—a point which previously was not clear. It would appear that the portion of the Temple discovered by Dr. Hall was the terrace of the main building which lay underneath. In the course of the present excavations, which have been made mainly in the south-east corner of the mound, one chamber has been found, which it is conjectured may be the innermost shrine, containing a valuable hoard of jewelry including many bracelets and necklaces, mostly of gold, and a tiled courtyard in which a gutter, such as was habitually used for collecting and carrying off the blood of a victim, suggests that it was the place of sacrifice. The cult of the Moon God was evidently re-established by Nebuchadnezzar, who made his daughters priestesses of the Temple, which he restored in the sixth century B.C., as is shown by an inscription. The upper bricks of the ruins were of this period, but those underneath were much earlier, and it is clear that in the restoration of the Temple the original foundations were, so far as possible, left untouched.

DR. CHARLES HOSE'S lecture on Sarawak at the Royal Colonial Institute on February 27 was opportune in affording material for a comparison in methods of administration and development with British North Borneo, an area which has attracted some little attention recently. Sarawak, a territory of some sixty thousand square miles, is perhaps best known in connexion with the romantic history of the Brooke family and as an independent native state under British protection, which has been ruled for nearly a century by a family of white men. It is, as Dr. Hose said, "perhaps the greatest achievement in state-making of the nineteenth century." It was founded by Sir James Brooke in 1840, and came under British protection in 1888 when its population numbered 600,000. The inhabitants include Malays, Dayaks, Kenyahs, Kayans, and a number of primitive tribes, still pagan, whose customs and beliefs have furnished, as readers of that valuable book "Pagan Tribes of Borneo," by Dr. Hose and Prof. McDougall, will remember, much material for the comparative study of religion, especially in connexion with their methods of divination and their belief in a spirit helper in animal form. The policy of the Brooke family has been to preserve, under an autocracy, as much of native custom as possible, retaining the great offices of state held by Malay nobles at the time of Sir James Brooke's accession to power, and associating the natives with the administration. As Dr. Hose pointed out in his lecture, several chiefs in bygone days endeavoured to establish peace through wide areas, but failed. To achieve enduring success the unifying influence of a central authority was needed. This has been furnished by the Rajahs, who, without breaking up old forms of society, have supplied elements lacking in the old system.

INFORMATION has been received that an All Russian Agricultural Exhibition will be held in Moscow on August 15–October 1. In a circular issued by the Russian Trade Delegation it is stated that foreign firms, institutions, and private persons are invited to participate in the exhibition, and that all privileges granted to Russian exhibitors will apply equally to foreign exhibitors. Special arrangements will be made to facilitate the delivery of exhibits, all such goods being given preferential treatment on the railways and waterways of the Republic, and for convenience of transit all foreign exhibits will be exempt from Customs examination at the frontier, provided that the goods bear regulation labels. Provision will be made for the insurance and safeguarding of exhibits, both during transit and at the exhibition itself. A fixed tariff of charges for space in the foreign section has been drawn up, all charges being payable in advance and not to be refunded if exhibitors renounce their allotted space or finally abstain from exhibiting.

THE Council of the Institution of Mining and Metallurgy has made the following awards: The gold medal of the Institution to Mr. Edgar Taylor, president, 1909–1911 and 1916–1918, in recognition of his services to the Institution since its foundation in 1892 and as an evidence of appreciation of his honourable record of work in connexion with the development of the mining industry, particularly in India; "The Consolidated Gold Fields of South Africa, Ltd." gold medal to Dr. Leonard Hill, in recognition of his valuable researches on ventilation and for his paper on "Ventilation and Human Efficiency," contributed to the Transactions; and "The Consolidated Gold Fields of South Africa, Ltd." premium of forty guineas to Mr. H. F. Collins, for his paper on "The Igneous Rocks of the Province of Huelva and the Genesis of the Pyritic Ore-bodies," contributed to the Transactions, and in recognition of his researches on the subject.

AN invitation is extended to Farmers' Clubs, Chambers of Agriculture and Horticulture, and other bodies interested in agriculture or market-gardening, to visit the Rothamsted experimental fields during the coming summer. The guide demonstrator is Mr. H. V. Garner, who for the past two summers has very successfully served in this capacity and has been able to make the visits both useful and interesting to farmers. Among important items of interest are: experiments on the manuring of arable crops, especially wheat, barley, mangolds, potatoes; manuring of meadow hay; effect of modern slags and mineral phosphates on grazing land, hay land, and arable crops; crop diseases and pests; demonstrations of good types of tillage implements, tractors, etc. At any convenient time between May 1 and October 1, there is sufficient to occupy a full day, and there is provision for assuring that the time shall not be lost, even if the weather turns out too bad to allow of close investigation of the fields. The director of the Station, Sir John Russell, will be happy to arrange full details with organisations of farmers, farm-workers, and others wishing to accept this invitation. Small groups of farmers are specially welcomed; if possible, arrangements should be made beforehand, but it is recognised that farmers' movements must often depend on the weather, and no one need stay away because he has been unable to write fixing a date.

THE departmental committee recently appointed to consider the present system of charging for coal gas on a thermal basis has now issued its report as a White Paper (Cmd. 1825, 6*d*.). The main recommendation is that the method of charging for gas on the thermal basis should be continued and extended to all statutory gas undertakings within the scope of the Gas Regulation Act. Thus is vindicated the really scientific method of asking the consumer to pay according to the amount of heat he receives. In the days of Argand and the flat-flamed fish-tail burners, light was produced by the combustion of the particles of gas in the surrounding air, and gas supply was then maintained at an illuminating standard. With the advent of the incandescent mantle, and the increasing use of gas fires, illuminatory properties in gas became of secondary importance to its heating values, and a calorific standard was introduced in 1916. The heat unit in common use in Great Britain for expressing the value of fuels has been, for many years, the British thermal unit, which is the amount of heat required to raise the temperature of 1 lb. of water 1° F. under appropriate conditions. This unit was used in gas calorimetry, and a gas was said to have calorific value of 500 British thermal units when 1 cubic foot gave out, when burned, sufficient heat to raise the temperature of 500 lb. (about 50 gallons) of water through 1° F. To obtain a conveniently practical unit, the therm, which is equal to 100,000 British thermal units, was adopted.

THE *Weekly Weather Report* for the week ending March 3, issued by the Meteorological Office, Air Ministry, gives a summary of the weather for the several districts of Great Britain for the past winter, comprised by the thirteen weeks from December 3, 1922, to March 3, 1923. The daily mean temperature for the period ranged from 40·1° F. in the east of Scotland to 46·9° F. in the Channel Islands. During the winter the extreme readings ranged from 61° in the Midland Counties to 15° in the east of Scotland, while in England the lowest temperature recorded was 22° in the Midland Counties and the south-east of England. Total rainfall was greatest in the north of Scotland, where the measurement was 18·52 in., which is 2·17 in. more than the normal; but the greatest excess on the average was 5·47 in., which occurred in the south-west of England. There was an excess of rain everywhere, the minimum excess being an inch in the east of England, where the total measurement was 6·53 in. Rain fell with greater frequency than the normal over the whole of Great Britain: the largest number of days with rain was 74 in the north of Scotland; the least, 53 in the north-east of England. The duration of sunshine was fairly equal to the normal in all districts. At Greenwich the mean temperature for the winter, December, January, and February, was 42·4° F., which is 2·9° above the normal for thirty-five years; temperature ranged from 57° to 24°. Rain fell on 49 days, which is 4 days in excess of the normal, and the total measurement was 6·60 in., which is 1·08 in. more than the average for thirty-five years. The duration of bright sunshine at Greenwich was 118 hours, which is 11 hours fewer than the normal.

NEWS received in Christiania, according to the *Times*, reports the arrival of Capt. R. Amundsen on December 15 at Nome, Alaska, from Wainwright, on the north coast, where he is wintering. His visit to Nome was to ascertain news of the *Maud*, which is now drifting across the polar basin. Capt. Amundsen expects to leave Wainwright or Point Barrow on his flight across the Pole to Spitsbergen in the middle of June. On March 6 a wireless message from the *Maud* reported her position as lat. 74° N., long. 170° 30′ E. The ship has drifted about half a degree

north and three degrees west of her position in the middle of December. Her speed of drift is about the same as that of the *Fram* at the same time of year, but the *Maud* is still well to the east of the New Siberia Islands and has not passed beyond the shallow and partially charted waters of the continental shelf.

H.M. THE KING has approved the grant of a Royal Charter of Incorporation to the Institution of Royal Engineers. The Institution, then known as the Royal Engineers Institute, was established as a voluntary association in the year 1875 for the general advancement of military science, and more particularly for promoting the study of such subjects as are of importance to the military engineer. In pursuance of its objects, the Institution has directed its efforts to the advancement of the science and art of engineering, especially in relation to their application to military purposes, and has thus been able to afford material assistance to those engaged in dealing with the important problems of defence connected with the British Empire. The Institution has during the past 47 years published 950 occasional, as well as other, papers on military and other scientific subjects; these papers, except those which are of a "Secret" or "Confidential" character, are available to the general public. *Inter alia*, the Institution now administers an important fund established in connexion with the award of scholarships to the children of deceased officers and other ranks who have fallen in the performance of their duties while on active service.

IN an article in the *Fortnightly Review* for March, Sir Charles Bright discusses the relation between the Empire's telegraphs and trade. He concludes that it is of national importance that there should be a great all-round reduction in cable tariffs. As this would doubtless result in greatly increased traffic it would necessitate laying many additional cables on different routes. He also dwells on the importance of the immediate completion of the Imperial "wireless chain," as well as alternative wireless chains. On March 5, Mr. Bonar Law announced that the Government is to proceed with the erection in this country of a state-owned and operated station capable of communicating with any part of the Empire. At the same time licenses are to be issued to private companies for the erection of stations in this country for radio-communication with any part of the world, subject to the conditions necessary to secure British control. The Marconi Company has thus been granted the license for which it has long asked, and it intends immediately to erect five large power stations to communicate with the Dominions and South America, and five smaller stations for more local traffic. The cost of these stations will be about two million pounds. It seems to us that this extension of long-distance communication will be of immediate benefit to this country, and the ensuing reduction in the tariff may induce the cable companies to co-operate with the radio companies. As Sir Charles Bright points out, this country has considerable leeway to make up; America, for example, uses 3400 kilowatts for its radio stations, and France 3150, while the British Empire only uses 700 kilowatts.

THE Spring Foray of the British Mycological Society will be held at Bristol on April 20–23. Headquarters for the meetings will be at the botany department of the University.

AN exhibition of Carboniferous corals has just been completed by Dr. W. D. Lang and Dr. Stanley Smith in the Geological Department of the British Museum (Natural History). Polished specimens and transparent sections have been prepared to illustrate the structure of each genus, and explanatory diagrams have also been added.

THE second annual general meeting of the National Institute of Industrial Psychology will be held in the rooms of the Royal Society on Tuesday, March 20. Among the speakers will be the Earl of Balfour, Sir Lynden Macassey, Dr. C. S. Myers, Sir Robert Hadfield, and Sir Charles Sherrington.

AT a representative meeting of botanists held at the Linnean Society's rooms on Friday, March 2, it was decided to hold an Imperial Botanical Conference of British and Overseas botanists in 1924 about the beginning of July. An executive committee was appointed, with Sir David Prain as chairman, Mr. F. T. Brooks as honorary secretary, and Dr. A. B. Rendle as treasurer. An invitation to attend the conference will be sent at once to Overseas botanists.

PROF. JOSEPH S. AMES, who gives an account of recent aeronautic investigations in the United States elsewhere in this issue, has been chosen to deliver the eleventh annual Wilbur Wright memorial lecture of the Royal Aeronautical Society. The lecture, the subject of which will be "The Relation between Aeronautical Research and Aircraft Design," will be given at the house of the Royal Society of Arts on May 31.

THE Royal Irish Academy devoted its meeting on February 26 to a commemoration of the centenary of Pasteur. Addresses were delivered by Dr. W. R. Fearon, Prof. A. C. O'Sullivan, and Prof. Sydney Young (president of the Academy), dealing with various aspects of his work, and an address in French by Prof. R. Chauviré dealt with Pasteur as a typical Frenchman.

A SCIENTIFIC superintendent under the Fishery Board of Scotland will shortly be appointed. He will conduct and supervise the scientific fishery investigations which the board may consider necessary, and be in charge of the board's laboratories at Aberdeen. Applications for the post, accompanied by copies of any published papers of the applicants, if deemed desirable, and the names of at least two referees, must reach the secretary of the board, 101 George Street, Edinburgh, by, at latest, March 31.

THE Ministry of Agriculture and Fisheries will shortly appoint an inspector in connexion with agricultural and horticultural education and research. Applicants for the position must have taken

a course in science or agriculture at a university or college of agriculture, and should have had special training in the science and practice of dairying. Forms of application and copies of the regulations governing the appointment may be had from the Secretary of the Ministry, 10 Whitehall Place, S.W.1. Application forms must be returned by March 26.

WE have received intimation of the opening at Lake Trasimeno of a laboratory for the study of the biology of the lake, including researches on the fresh-water fishes. The lake, which is about thirty miles in circumference, offers many opportunities for limnological work. It is to be hoped that this new station will receive the support which will justify its continuance. The premises have been provided by the University of Perugia, and Dr. Osvaldo Polimanti, professor of physiology in the University, has been appointed director, and intending workers should communicate with him.

MR. G. M. B. DOBSON will deliver a lecture to the Royal Meteorological Society on March 21 on "The Characteristics of the Atmosphere up to 200 km., as obtained from Observations of Meteors." Meteorological observations in the free atmosphere by means of *ballons-sondes* have not been carried to heights much greater than 30 kilometres, but Prof. Lindemann and Mr. Dobson have recently put forward a method of determining the temperature at much greater elevations by means of observations of meteors (see NATURE, December 9, 1922, p. 794). Those interested are invited to attend the meeting, which will be held in the Society's rooms at 49 Cromwell Road, South Kensington, London, S.W.7.

AT the annual general meeting of the Institute of Metals held on Wednesday, March 7, the following officers for the year 1923–24 were elected:—*President*: Mr. Leonard Sumner. *Past-Presidents*: Sir Gerard A. Muntz, Bart., Engineer Vice-Admiral Sir Henry J. Oram, Sir George Beilby, Prof. H. C. H. Carpenter, and Engineer Vice-Admiral Sir George Goodwin. *Vice-Presidents*: Sir John Dewrance, Mr. W. Murray Morrison, Sir Thomas Rose, Dr. W. Rosenhain, Sir William E. Smith, and Prof. T. Turner. *Honorary Treasurer*: Mr. A. E. Seaton. *Members of Council*: Mr. W. H. Allen, Mr. L. Archbutt, Mr. G. A. Boeddicker, Mr. T. Bolton, Dr. H. W. Brownsdon, Engineer Vice-Admiral R. B. Dixon, Prof. C. A. Edwards, Mr. S. Evered, Dr. R. S. Hutton, Mr. F. C. A. H. Lantsberry, Sir Charles A. Parsons, Mr. H. A. Ruck-Keene, Dr. R. Seligman, Mr. James Steven, Mr. F. Tomlinson, and Mr. H. B. Weeks.

Our Astronomical Column.

GREAT FIREBALL IN NORTHERN INDIA ON DECEMBER 28, 1922.—Mr. W. F. Denning writes that "letters have been received reporting a splendid fireball which appeared over the Punjab at about the time of sunset on December 28. It was observed by a great number of people, and accounts published in the *Civil and Military Gazette* (Lahore) include descriptions from Simla, Peshawar, Balloki, Moghalpura, Sargodha, Jhelum, Rawalpindi, Bakloh, Dharamsala, Lahore, Sharaqpur, Murpur, and other stations.

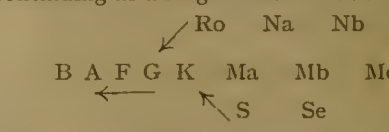
Many of the accounts are of little service, but Col. W. E. Pye and Lieut. Stephenson at Shagai, Khyber Pass, North-West Frontier, give an excellent description of the phenomenon. The observed path at the latter place was from 6°-43° to 20°-48°, and the fireball exhibited moderately slow motion. It left a long white streak which endured about fifteen minutes. A large number of the observers allude to the streak as perfectly straight at first, but it soon assumed a zig-zag shape, and drifted away from the place of its early projection. At one station the streak, which appeared to be vertical when formed, became horizontal in twelve minutes, the lower end having moved the required distance. At Sargodha, six minutes after the great illumination due to the meteor, loud rumbling sounds were heard, caused by the disruption of the object. These would indicate a distance of 75 miles.

From a comparison of the observations the fireball seems to have been an early Quadrantid with a radiant at 234°+55°. The height was about 54 to 29 miles, and velocity about 25 miles per second. The luminous course was directed from N.N.W. to S.S.E. It crossed the river Chenab, and ended about 100 miles N.E. of Mooltan.

These results are only approximate. The object was one of great splendour, and it is hoped that further observations will be forthcoming.

STELLAR SPECTRA OF CLASS S.—In the current number of the *Astrophysical Journal* (December 1922) Mr. Paul W. Merrill directs attention to a number of red stars having spectra similar to that of R Geminorum, which differ from any of the well-known types of spectra which form the Harvard classification. In this classification the red stars are known as M and N types and each of these is subdivided, but no stars are known which have a spectra intermediate between them; M stars have characteristic titanium flutings and N stars carbon flutings. This peculiarity has led to the adoption of a break in the main series of stellar evolution types of spectra.

Thus an M star of increasing temperature becomes consecutively in the evolutionary series a K, G, F, etc., type star, while an N star, also a giant, becomes an Ro, G, F, etc., type star in its progressive stages. Mr. Merrill shows in this paper that the stars he has discussed should properly form a third division of the giant series joining on to the main sequence of evolutionary stages between the types Ma and K. This progression may be likened to three sets of railway lines joining up at two positions near each other and continuing as a single line. Thus:



It is interesting to note that the Harvard classification is based to a great extent on the replacement of metallic lines by ionised lines, and eventually by gaseous lines, the higher the temperature; but Mr. Merrill points out that while some M stars show ionised lines, so also do the S stars; this presents, as he says, "an anomalous circumstance which invites investigation."

Research Items.

AFRICAN SIGN WRITING.—Mr. C. W. Hobley in the Journal of the East Africa and Uganda Natural History Society, No. 18, March 1923, has given some examples of sign writing collected in East Africa. It includes reproductions of the large fauna of the country, giraffe, elephants, and the like, and their spoor, supposed to indicate to the friends of the artist the presence of game in the vicinity. Others seem to be marks of locality and property. The custom of using signs still survives among the natives. In Togoland, if a man calls on a friend and finds him absent, he will pull a little grass from the roof of his hut and attach it to a stick outside the door to announce to the owner that a visitor has called. Wemba hunters make marks on their arms to record the number of the bigger animals they have killed, and in some parts of Kavirondo the birth of each child is marked by a cicatrisation on the abdomen, possibly with some magical object. The facts collected by Mr. Hobley and the illustrations he has provided are interesting in connexion with the origin of writing.

THE CATHOLIC CHRISTIANS OF EASTERN BENGAL.—Little has hitherto been known of the remarkable community known as the Firingis or "Franks" of Eastern Bengal. The late Dr. James Wise gave some account of them in the very rare volume entitled "Notes on the Races, Castes, and Trades of Eastern Bengal," of which only twelve copies were privately printed in London in 1883, and even libraries like those of the British Museum, the University of Cambridge, and the Royal Anthropological Institute do not possess a copy. Some of the information was, however, copied by Sir H. Bisley in his "Castes and Tribes of Bengal." Some fresh details of this curious people have now been collected by Mr. H. E. Stapleton, special officer of the University of Dacca, and published in vol. xvii., 1922, of the Journal of the Asiatic Society of Bengal. They are believed to be descended from the Portuguese pirates who infested the Delta of the Ganges in the sixteenth and seventeenth centuries. They undoubtedly include many converts from the local races, they speak nothing but Bengali, are indistinguishable from Bengalis in dress and means of livelihood, and until recently they made no claim to Portuguese descent. They now number about 8500, but of these, 2000, under the French Fathers, are converted natives and have no claim to the name Firingi.

PRODUCTIVITY OF HILL PASTURES.—An inquiry conducted into the productivity of hill pastures in Exmoor, Wales, and Northern England ("University of Oxford Institute for Research in Agricultural Economics: The Productivity of Hill Farming," by J. Pryse Howell, London, Oxford University Press, 1922. 1s. net) has shown the value of artificial manuring of pasture and of more intensive cultivation in increasing the production of mutton, wool, and beef per acre. Much improvement in this direction is possible on the lower-lying ground, but it is less practicable on farms with an extensive range of high sheep-walks. The improvement of the latter will always be difficult owing to the considerable cost involved, but the committee of inquiry make certain recommendations which could well be carried out. Much depreciation of flocks occurs, especially in Wales, from the practice of allowing the rams to roam at will over the unenclosed sheep-walks, and it is recommended that a more efficient system of control of rams be instituted and enforced. The management of the "Commons" with grazing rights is very unsatisfactory, and joint action by the commoners is essential if matters are to be improved. Bracken, heather, and gorse are too often allowed to grow unchecked, thus reducing the feeding value of the land, and the systematic burning of heather and gorse, and the eradication of bracken, would prove most advantageous. The mortality among the flocks from various diseases is very heavy, and causes great monetary loss, and the committee emphasise the fact that a systematic inquiry into the diseases affecting sheep is a matter of the most urgent importance.

RUSTS IN SOUTH AFRICA.—The great economic importance of rusts, owing to the considerable loss in crops that they cause, renders it essential to determine the life history of as many types as possible in order to discover the second host where unknown. Infection experiments have shown that the common rust on *Vigna angustifolia* produces spermagonia and æcidia on this species from October to January, and then infects the Besem gras (*Tristachya rehmani*) by means of æcidiospores (M. Pole-Evans, Union of S. Africa, Science Bull., Nos. 1 and 2 of 1923). Uredospores and teleutospores are produced on the second host, the winter being passed in the latter stage, and with the fresh growth of the Vigna in spring, infection occurs by sporidia developed from the resting teleutospores. This rust on sweet pea and Besem gras is a new species of Puccinia which has not yet been described and named. A similar life cycle has been established for the mealie rust (*Puccinia maydis*), of which the spermagonia and æcidia occur from October to December on *Oxalis corniculata*. This connexion was originally established by Dr. Pole-Evans, and has now been confirmed by these infection experiments. Other species of Oxalis tested proved to be quite immune.

COLOUR INHERITANCE IN SEEDS AND FLOWERS.—In a paper showing the inheritance of certain brown and red pigments in the seeds of soy bean and rice varieties, Mr. I. Nagai (*Journ. Coll. Agric.*, Imp. Univ., Tokyo, vol. 8, No. 1) has also made experiments on the physiology of the pigments involved. They are in two groups, the anthocyanins and the reddish-brown phlobaphenes. The whole subject of the genetic physiology of these pigments is discussed, and the limitations in our knowledge of the relations between genes, chromogens, and enzymes in colour production are pointed out. In the same Journal, Dr. S. Ikeno describes the genetics of flower colour in *Portulaca grandiflora*. The condition of colour inheritance resembles that in various other genera, the factor C producing an orange colour, C+G yellow, C+R red, while magenta, which is probably the original colour, is produced by C, R, and a blueing factor B acting together. R and B generally show complete linkage, but occasional crossing over produces red-flowered plants. Reverse mutations were also obtained, from white to magenta or red, as well as bud mutations, which were already known. Drs. K. Miyake and Y. Imai (*ibid.* vol. vi. No. 4) similarly analyse the flower colours of *Digitalis purpurea*. The purple colour is due to the presence of two factors C and P. When P is absent the flower is white with red spots, while in the absence of C it is white with yellow spots.

THE STRENGTH OF THE PLANT CUTICLE.—Botanists have recognised the importance of this question since the investigations conducted at the Imperial College of Science under the direction of Prof. V. H. Blackman have led to the conclusion that some parasitic fungi pierce the cuticle of the uninjured plant purely by pressure. They will therefore find

considerable interest in the conclusion drawn by recent writers in the Journal of the Textile Institute as to the surprising strength of the cuticle surrounding a cotton hair. From different lines of investigation this result is arrived at by R. S. Willows and his co-workers in the Research Department of Tootal, Broadhurst Lee Co., Manchester, in their experiments upon mercerisation (Journ. of the Text. Inst., xiii. pp. 229-40, December 1922), and by H. F. Coward and L. Spencer upon the absorption of caustic soda solutions by cotton (Journ. of the Text. Inst., xiv. pp. 832-45, Jan. 1923). All these investigators conclude that the swelling of the cotton hair in alkali may be considerably restricted by the resistance to expansion of the cuticle and give cogent grounds for this conclusion. Such a strong cuticle upon a hair which has largely matured within a closed fruit is at first sight a surprising phenomenon. It is interesting to note that H. J. Denham, in his study of the destruction of the cotton hair by micro-organisms (Journ. of the Text. Inst., xiii. pp. 240-48, Dec. 1922), inclines to the view that some of these organisms can penetrate the healthy cuticle. This cuticle resists cold alkalis at high concentration and its hydrolysis by any organism has yet to be detected; but in view of these studies upon its strength, the actual method by which the uninjured cuticle is penetrated would seem to deserve close investigation.

IMPOUNDING WATER FOR MOSQUITO CONTROL.—In Bulletin 1098 of the U.S. Department of Agriculture, 1922, Mr. D. L. van Dine describes a method of controlling the breeding of malaria mosquitoes in the lower Mississippi Valley. In this region the bayous or shallow streams of the delta, with their accompanying vegetation, greatly facilitate the breeding of anophelines. The topography renders drainage impossible, and a trial was therefore made of clearing a section of the bayous and impounding the water so as to convert what was practically a marsh into a lake. The essential points in this method are the preliminary clearing of all vegetation, the provision of a sufficiently high permanent level of water, to suppress the further growth of aquatic and semi-aquatic vegetation, and the maintenance of a clean margin. The experiment thus carried out is stated to have given good results.

GROWTH OF CASSAVA PLANTS.—T. G. Mason has an interesting note in the Scientific Proceedings of the Royal Dublin Society, vol. 17, N.S. Nos. 11-13, pp. 105-112, December 1922, upon the growth of some Bitter Cassava plants in St. Vincent, West Indies, under equivalent conditions save that half the plants were ringed through the phloem near the base of the stem, measurements of growth being made both before and after the operation. The experimental results show that this ringing did not affect the growth in length of the shoots for several weeks and then only to a relatively small extent; the fleshy roots, on the other hand, accumulated far less weight of reserve material upon the ringed plants. The author scarcely appears to put the simplest interpretation upon these experimental results when he declines to assume that the normal channel for the passage of this food to the root has been interrupted by cutting through the phloem, but assumes instead that the ring has blocked the passage of some mysterious correlating agency from the dominant apical shoot bud, and that in the absence of this unknown factor normal transmission of organic solutes in the xylem is impossible.

ORIGINS OF PETROLEUM.—In an important paper on the marine kerogen shales from the oil-fields of Japan (Sci. Rep. Tohoku Imp. University, Ser. 3, vol. 1, No. 2, 1922, Maruzen Co., Tokyo), Mr. Jun-ichi Takahashi describes a number of interesting deposits of Miocene and Pliocene age from various islands of the Japanese group, including a series where radiolaria, sponge-spicules, and diatoms are associated with what was originally sapropelic matter. The author concludes that the kerogen has arisen from "nectons and kelps" which have "been repeatedly buried by ash and detritus from submarine volcanoes." He illustrates the memoir by photographs of rocks and marine fossils, and of a remarkable series of thin sections of the sapropelic ooze.

CANNEL COAL, LIGNITE, AND MINERAL OIL IN SCOTLAND.—The Geological Survey has published recently volume xxiv. of its special Reports on the Mineral Resources of Great Britain, which gives an account of a number of minor occurrences of cannel coal, lignite, and mineral oil in Scotland outside the recognised Scottish oil-shale fields. The work has been done by a number of members of the staff of the Geological Survey, and the publication is edited by Dr. W. Gibson. It is of course important that all such occurrences should be put on record, although, as is pointed out in the memoir itself, they have little or no economic value; nevertheless they are of interest to the geologist, and the information here given may prevent waste of money and energy in attempts to develop them.

THE WARIALDA METEORITE OF NEW SOUTH WALES.—The Warialda meteorite, which is defined as a fine variety of hexahedrite, has been described, figured, and its analysis given by J. C. H. Mingaye (Rec. Geol. Surv. N.S. Wales, vol. x. part 1). It is identical in crystallographic structure with the Bingera and Barraba meteorites which were found in the same district, and the three are probably products of the same fall, of which it is hoped further specimens may yet be discovered.

ORTHOPTEROUS INSECT WING IN A SELENITE CRYSTAL.—In the Mount Elliott Copper Mine, North Queensland, at a depth of 260 feet from the surface, and embedded in a large crystal of selenite, enclosed in the actual copper lode worked in that mine, there has been found a portion of the wing of an Orthopterous insect. This interesting fragment forms the subject of a paper by Dr. R. J. Tillyard in the Records of the Geological Survey of New South Wales, vol. x. part 2. The crystal must have been formed by percolating waters long after the lode itself came into being; its age is, consequently, very uncertain, but the author inclines to the view that it is late Tertiary. The conclusion reached after a careful study of the fossil is that it represents an archaic type belonging to the family of long-horned grasshoppers (Tettigoniidæ), and does not belong to any genus known to exist in the world to-day. Accordingly it has received the name of *Austrodictya corbouldi*, n. gen. et sp., the trivial name commemorating the manager of the mine through whose instrumentality the specimen was saved from destruction and forwarded to the Survey.

NEW BRUNSWICK OIL-SHALE AND GYPSUM DEPOSITS.—Memoir 129 of the Geological Survey of Canada records the geology of the Moncton Map-area, which includes parts of the counties of Westmorland and Albert lying in south-east New Brunswick. Besides giving an account of the general geology of the district, incidentally the geology of the Carboniferous rocks for the most part, the memoir gives some new facts relating to the oil-shale deposits. These shales are associated with certain horizons in the Carboniferous sequence, and an effort has been

made to elucidate the structures accurately to enable the extent of the resources available to be calculated. Actual oil and gas possibilities are practically negligible, but the shales at places like Albert Mines and Rosevale are both well known and valuable, while several other localities offer good prospects. Since May 1921, the D'Arcy Exploration Co. (a subsidiary of the Anglo-Persian Oil Co.) has been operating at Rosevale, mainly on experimental lines with a special type of retort (Wallace), and the results have so far proved quite satisfactory. The average recovery of oil from a ton of shale is about 30 gallons, the specific gravity of the product varying from 0·893 to 0·903. This compares favourably with that obtained from the Scotch retort on the same material, where the yield is less and the gravity of the oil usually higher. Some gypsum and anhydrite deposits described from the region also form interesting and economically valuable occurrences: these are in the Hillsborough Series of Mississippian age and are at present being worked in the Demoiselle and Hillsborough basins. The relationship of the gypsum to the anhydrite deposits appears to be obscure here, as is frequently the case elsewhere; but the theoretical problems to be solved have a direct bearing on the future working of the deposits.

CLOUD FORMATION.—The Royal Magnetical and Meteorological Observatory of Batavia, in Verhandelingen, No. 10, gives a discussion by Dr. C. Braak on cloud-formation, nuclei of condensation, haziness, and dimensions of cloud-particles. The data were determined by means of Aitken's dust counter. In addition to the observations made in the East-Indian Archipelago an appendix is given on observations made in the Indian Ocean during a voyage from Java to Europe. Observations were also made on dry fog in the Archipelago as well as in other regions. Individual observations are published, so that the details can be examined. The differences between land and sea are given, and the variations with height above sea-level. The number of nuclei in the open sea under humid conditions was 120 per c.cm., and in the open sea in the dry season 1620 per c.cm.; in the neighbourhood of the land the mean number was 2560. The variation with height above sea-level shows a great decrease in the number of nuclei with increased height. Seasonal variations are considered, dealing chiefly with observations in Java and Sumatra. Much of the haze experienced is attributed to smoke from forest and prairie fires. The size of the particles is said to have a larger influence than their number on the density of haze, careful observations being made with a microscope to test this view. Valuable generalisations have been made on the subject, and these will doubtless be tested by other observers. This paper was taken as the subject for discussion at the evening meeting at the Meteorological Office on February 5, and is referred to in the *Meteorological Magazine* for February.

THE ELECTRICAL CONDUCTIVITY OF GLASS.—The February issue of the Journal of the Franklin Institute contains a communication from the director of the Applied Science Section of the Nela Research Laboratories, giving the results of the research of Mr. L. L. Holladay on the conductivities of glasses at temperatures up to 500° C. Between 20° and 75° C. the resistance from the inside to the outside of the glass tubes used was measured, and at higher temperatures the resistance of a length of the tube. In all the eleven glasses tested the conductivity could be expressed as the product of a constant into a power of the temperature centigrade about $-\frac{1}{2}$, into ϵ, the base of the Napierian logarithms, to the power $-A/T$, where A is a constant and T the temperature centigrade. A table of values of the constants for the glasses tested is given.

HEATING IN ELECTRIC CONDUCTORS.—An important research on the heating of buried cables has just been communicated to the Institution of Electrical Engineers by Mr. S. W. Melsom and Mr. E. Fawssett. Most of the tests were made at the National Physical Laboratory, but some were made under actual working conditions, the cables being laid in all kinds of soils. The rating of a cable depends on the rate at which it can dissipate the heat generated in it by the electric current, and hence it was necessary to calculate what current it could carry under different working conditions. Apparently the thermal conductivity of the insulating material of the cables does not vary appreciably with temperature, and thus the solutions of the thermal problems which Fourier gave in his "Théorie analytique de la chaleur," published in 1822, apply. The thermal constants of various kinds of soil are given, and so by the help of formulæ the maximum permissible currents in the various cases can be readily computed. It was found that in certain cases existing cables could carry greater currents safely, and hence economies can be effected. The research, which was a costly one, has taken several years, and was carried out on behalf of the British Electrical and Allied Research Association.

A RECORDING SACCHAROMETER FOR BREWING.—Messrs. Negretti and Zambra have constructed an instrument known as a hydrograph or recording saccharometer, which is compensated for temperature. It has been designed and constructed to provide a simple and practical means of showing and recording the specific gravity of wort flowing to the under-back, copper, etc. It consists of a cylindrical vessel on the lower portion of which is a $\frac{3}{4}$-in. pipe, through which the wort is admitted. To prevent eddies in the vessel, an inlet pipe leads into an annular ring, which distributes the flow evenly round the vessel. A cylinder and copper gauze is also provided through which the wort percolates. An outlet pipe at the top of the external cylinder is provided, and here again there is another annular ring over which the wort flows, with the object of preventing eddies. Within the inner copper gauze cylinder a hollow float of thin nickel heavily coppered is suspended. The hollow float is completely filled with the liquid, and is connected with the recording instrument by means of a chain immediately above the vessel. The chain is connected with a grooved quadrant mounted on a knife-edged axis. On the opposite side a weight is provided to balance the float when it is in the liquid, the zero adjustment being provided by an adjustable weight. The indications of the instrument are rendered independent of temperature from the fact that the wort in the cylinder and in the float are at the same temperature. The clock carrying the chart revolves once in six hours, and the graduated portion of the chart is marked from 1000 to 1100° specific gravity, and subdivided to 2° specific gravity, which on the chart is equal to $\frac{1}{10}$th of an inch. The pen marks in a continuous ink line on the chart, and the readings can be made to $\frac{1}{4}$° specific gravity with the greatest accuracy. In an ordinary mash tun, however, the wort from the various taps are often running at different temperatures and at a different specific gravity, so that the measurements made with the wort from one tap will not of necessity give the average specific gravity of the whole wort. The objection does not apply if the wort is drawn off through one spend pipe or is running from the under-back to the copper.

Humanism in Technical Education.[1]

By Sir THOMAS HOLLAND, K.C.S.I., K.C.I.E., F.R.S.

VERY few questions have been more discussed than that of education, and the reason for it is quite obvious; for educational methods are as varied as the students who have to be educated, and perfection can be reached only when a system is designed to meet the special circumstances of each individual. Some plants want pruning, others require fertilising, to produce their best results. One pedagogue thinks discipline should be the cure for all students' evils; others preach the importance of making the work attractive. The clash of ideals is heard most in our technical schools. One authority wants full-scale machinery, another says that the college workshop is merely a misleading caricature of a commercial factory. We are told that the student of science and technology can never become an educated man without a dose, and a fairly large dose, too, of the so-called "humanities"; he must always be narrow otherwise, if not absolutely lopsided, and can never be prepared in an institute of science and technology efficiently to undertake the full duties of citizenship.

In a community of science workers discordant notes are similarly heard. One presses for pure science as the main requirement of the practical technologist; another urges training in purely technical methods. The practical man thinks he has used a very hard word indeed when he calls the science student a theoretical idealist, a dreamer. The student of science pretends to despise the practical man as a mere rule-o'-thumb worker, often, however, because he fails to grasp the principles which underlie, and the long process of expensive research that has evolved, the so-called rule-o'-thumb. The doctrinaire student of science very often is, as some one has said of the early riser, conceited all the morning and stupid for the rest of the day.

It is, however, impossible to lay stress on any one truth without apparently being unfair to some other truth. Somewhere between these extremes the maximum of truth is to be found. It is too often so that where science is taught, the student is crammed with the facts instead of trained in the methods. The product of the science class is sometimes handicapped by what Prof. Huxley, the greatest of my predecessors at South Kensington, called "precocious mental debauchery"—the result of too many bouts of book-gluttony and lesson-bibbing.

I do not intend this evening to follow up any of these apparently divergent doctrines. We have learnt now, if we never appreciated it fully before, that a country cannot defend itself in war, or fight the relentless battles of peace, without science and technology. But the technologist will not remain only an expert in the workshop. He has duties as a citizen and must face relations, and competitive relations too, with other human beings, with most of whom he is unable to communicate in technical terms alone—the technical terms that he learns in the class-room. To be appreciated, he must understand and be understood by others: he wants the "humanities."

Now what is meant by the "humanities"? A dictionary will tell you that classical learning is intended by the same word that we also use for a study of the dispositions and sympathies of man. Sure enough, the study of classical literature once had this meaning. Late in the middle ages the study of the classics revealed to the world the long-buried wisdom, especially of the Greeks—their art, their religion, and, more important, their science. That discovery gave rise to the great movement which we speak of generally as the Renaissance—the revolt of intellect from previous feudalism and theological bondage—resulting not only in the revival of literature, art, and that religious freedom which is generally known as the Reformation, but in the development also of scientific curiosity, what, to avoid the secondary meaning of curiosity, we now call research. It gave us the Copernican for the Ptolemaic reading of the solar system; it gave us also in practical form the mariner's compass and, with the exploratory spirit which accompanied it, the discovery of the Americas, of South Africa, India, and the Far East; it gave us the invention of gunpowder and that of paper and printing, which facilitated the distribution of the new learning to a wide world.

How many of these developments, which succeeded one another with the speed of a revolution, were due to independent origin and from other sources, and how many were quickened by the rediscovery of buried philosophies, we need not stop to inquire; but it is obvious that what would otherwise have been but slow combustion developed, because of this discovery, at the speed of an explosion. That discovery was specially the discovery of humanism in Greek literature. Greek literature acted on medieval scholasticism like nitric acid on a combustible cellulose; cotton was converted into gun-cotton.

The lesson to be learnt from the Renaissance is strengthened by a consideration of what happened afterwards to classical studies. With the passage of time, classical learning like an organism went through a period of vigorous youth, vitalising the world with new energy and new ideas, until it reached the stage of adolescence, and, with it, specialisation.

That is the life-history of every organism. With specialisation the study of the classics became narrowed to its linguistic, grammatical, and purely rhetorical aspects: its main object became obscured and stricken with a formalism and a pedantry that "has given us false ideas, and the narrow spirit of a mutually admiring coterie, that wrote Latin and Greek verses to one another and to no one else. It has engendered a wild form of pedantry that regarded a false concord or a false quantity in Greek, not at all as we should regard a similar mistake in French, but as a shock to the higher order of things, which deserved scorn and reprobation when committed by a man, cruel punishment when committed by a boy."

These are not the words of a prejudiced and jealous scientific man, but the judgment of a distinguished classical scholar, the present Vice-Chancellor of Oxford. Reviewing the situation in this way before the Congress of Universities in 1921, Dr. Farnell pleaded for the revival of humanism in classical studies, and I wish similarly to direct attention to the importance of humanism in science and technology, for we also are exposed to the very same danger that Dr. Farnell says has now nearly strangled classical scholarship in our public schools and younger universities. We can thus learn something from the classics; we can profit by their mistakes, knowing that it is never so easy to recognise our own as the mistakes of others.

[1] From an address delivered at the Sir John Cass Technical Institute on January 31.

During the middle two quarters of the nineteenth century, science went through what we might call its Renaissance period. In its philosophical aspects, it was a revolt in part against a widespread misinterpretation of theology, and, in educational policy, it was a revolt against the dominance of what we regard as a perverted and senile form of the classical humanities. We do not object to the humanities, but to that devitalised residue of the humanities that is without humanism.

I am not now going to discuss the relative merits of science and classics as educational media, but I want to bring home to you the danger of defeating the very end of science itself. Scientific men are also liable to succumb to that form of pedantry which in classics exchanged humanism for grammar and rhetoric, and that homologue of pedantry in most religions which tends to kill doctrine by ritual. Do not let us claim that science can give mental training as good, when really we mean as bad, as that afforded by classics. You may remember what Huxley said of Peter Bell, whose dead soul, according to Wordsworth, saw nothing in Nature:

> "A primrose by the river's brim,
> A yellow primrose was to him,
> And it was nothing more."

Huxley asked if Peter Bell's apathy would have been roused one whit by the information that the primrose is a dicotyledonous exogen, with a monopetalous corolla and central placentation. This additional information would have added no more to the humanising influence of the primrose on Peter Bell than any form of exegetical analysis of a Greek text in exchange for Greek philosophy and Greek art.

Let us take an illustration from one of the departments of this Institute—that of metallurgy. The syllabus of this subject refers to "Bessemer and open-hearth plant and processes." A fair summary of what I, as a junior student, had to learn under this head would be as follows: "The original Bessemer process, as conducted in a ganister (silicious) lined converter, does not effect the elimination of phosphorus from the pig-iron; but by using a basic (dolomitic) lined converter, Thomas and Gilchrist found it possible to eliminate the deleterious element that affects the quality of the resultant steel, so it is now possible to use a phosphoric pig-iron for steel making." Later, coming under the influence of a professor with a wider outlook of the world, I learnt that this so-called basic process changed the whole of our international relationships. It opened up the enormous phosphoric ores of Germany, Belgium, and America. It resulted, therefore, in a challenge to British supremacy in the steel business. Just think of what that meant to railway development, shipbuilding, machinery, and dozens of dependent industries! Obviously, realisation of this, to me, quite unforeseen meaning in a purely technical fact opened up a new world of human interest.

Who was Thomas and who was Gilchrist? Those were the first questions that occurred to one. Thomas, I found, was a magistrate's clerk who attended evening science classes at the Birkbeck, a college having an object similar to that of the Sir John Cass Institute, and named for the same good reason after its founder. Gilchrist was his cousin, and he proved to be much more interesting to me, for he was an old School of Mines student and a Murchison medallist.

Thomas and Gilchrist made, by their invention, a greater impression on the history of civilisation than any two Prime Ministers we have ever had, a greater influence than the sum-total of that exercised by one devoted to optimistic militancy and his counter-irritant, the apostle of tranquillity. Thomas had what the great Mr. Gladstone described, in reviewing his memoirs, as "an enthusiasm of humanity." I am ready to assert that a review on these lines of the way in which the basic process of steel-smelting has affected history, especially when so touched with the human relations of the two men to whom it is due, is all that is necessary for the student. He will soon satisfy his own curiosity about technical details; he will soon be studying the question himself in the library and the workshop.

This stirring of that form of curiosity that Dr. Johnson called "the thirst of the soul" and "the characteristics of a vigorous intellect" will give human, living interest to a student's work. The teacher's task is three parts done and faithfully fulfilled when he has inspired the student sufficiently to impel him to find out the rest for himself. Nothing appeals to a man like humanity.

In a thoughtful paper read before the Congress of Empire Universities in 1921, Prof. Cecil Desch advocated the adoption of the historical method in science teaching. But history consists of innumerable biographies. As Emerson said, "There is properly no history, only biography." History, divorced from biography, can be as dull and deadening as either Greek grammar or descriptive technology. The educational balance is not secured by requiring students to attend a formal course of classics or history as well as of science. That would be merely to double the offence. A physician does not apply a counter-irritant if he can get at the seat of the disease. It is not separate courses of history and science—a mechanical mixture—that are wanted, but the history of science itself, that is, a chemical compound. Giving two separate doses of two unrelated subjects to act as mutual correctives is equivalent to giving a man a metallic sodium pill with a sniff of chlorine gas, when what he wants is merely a pinch of common salt.

But for the power unwisely given to examiners to make or mar a student's career, I would like to try the experiment of covering a syllabus of, say, metallurgy or chemistry by lectures on biography alone. I believe students could be trusted to fill in the historical frame-work on their own account, and to find out for themselves all that is required in the way of technical details. They shall succeed, of course, in varying degrees just as they do now; but whether they succeed partially or wholly, all shall be better men for having made an effort inspired by a natural and healthy curiosity; they shall have had the very training which lays a sure foundation for what the scientific man calls research; and what the scientific man calls a training for research is the very kind of training which qualifies a man to face the problems of after life, when every difficulty that the student has to face after he has left the institute shall have no apparent resemblance to any question previously treated, either in the lecture-room or the laboratory. Every problem that the student meets with afterwards shall be a piece of new research to him.

Sir Richard Gregory, in his address to the British Association last year, defined education as the "deliberate adjustment of a growing human being to its environment; and the scope and character of the subjects of instruction should be determined by this biological principle." I agree, and as the technical student's environment will be human beings, with little or no familiarity with his own pet technical terminology, he wants to go into the world with a full appreciation of the human aspects and importance of his special subject.

The Flora of an Indian Island.[1]

AS a preliminary to the faunistic study of Barkuda, one of several islands in the Chilka Lake, Dr. N. Annandale has investigated its climate, physical structure, palæontology, and vegetation. The lake is a maritime one in the extreme north-east of Ganjam, and is connected with the Bay of Bengal. The island, some three hundred acres in extent, though isolated for terrestrial animals, is within the range of insects of feeble flight and that of dispersal for many seeds. The climate is that of the coasts of the Circars to the south and Orissa to the north. The physical structure is simple and the geological formation uniform; the rocks are the quartz schists of the Ganjam Malias. The changes in the shore water-level, though of faunistic importance, scarcely affect the vegetation. The rocks contain no fossils, but sub-fossil molluscan shells abound in the soil of the island and the sand of its shores. These shells indicate that the island, as such, is recent; the age of the rocks has no bearing on its existing biological features.

Though the vegetation is restricted, several types occupy different areas. Much of the surface has been colonised primarily by species of Ficus, mainly *F. bengalensis*, with an undergrowth of Glycosmis and a partial thatch of woody climbers. This is gradually replaced by other species of Ficus accompanied by trees like *Melia Azadirachta* and *Strychnos Nux-Vomica*, while the undergrowth is reinforced by Capparis and Zizyphus. The foreshore vegetation is scanty. Where the coast is rocky the species present, though fewer than on sandy or gravelly sections, are arboreal and therefore more conspicuous. Behind the foreshore comes a Pongamia belt, broken in places by intruding Cratæva and Melia. Within this zone, besides surviving Ficus groves with Glycosmis undergrowth, are areas where the latter is replaced by *Weihea ceylanica*, the former by Cratæva, Odina, and Albizzia. Stony areas have a scanty plant-covering; the rock-flora of the interior includes masses of two arboreal Euphorbias, *E. antiquorum* and *E. neriifolia*. The commonest tree on the island is *Melia Azadirachta*; perhaps the most abundant herb indigenous there is *Oldenlandia Heynei*.

Dr. Annandale's ecological sketch is supplemented by a plant-list prepared from his specimens by two members of the Botanical Survey staff. This important adjunct to the paper is somewhat marred by typographical errors, and shows want of uniformity in citation. Messrs. Narayanaswami and Carter have not supplied an analysis of the vegetation from the point of view of plant-distribution to correspond with Dr. Annandale's discussion of the subject from the point of view of plant-association. Their carefully prepared list provides all the material required for the purpose, but they have made it more troublesome for those desiring to ascertain the facts by adopting a taxonomic system which, whatever its academic merits, has the inconvenience of differing from that used in the "Flora of British India."

The affinities of the Barkuda flora are South Indian. The list enumerates 139 plant-forms, of which two may be new while five remain undetermined. The remaining 132 include twenty-one, nearly 16 per cent., not reported from Orissa north of the lake, and seventeen, nearly 13 per cent., never found north of the Dekhan. One species, *Riccia crispatula*, has hitherto only been known from Ceylon; two, *Selaginella tenera* and *Weihea ceylanica*, have only been reported from Ceylon and from India south of the Dekhan. Thirty-five, more than 32 per cent., of the Barkuda species reported from North-eastern India, are themselves indicative of South Indian affinity. Seven are littoral plants that are North-eastern Indian only, because they occur on the Orissa coast and in the Sundribuns. The remaining twenty-eight include ten reported only from Orissa, which is a northward continuation of the Circars, and eleven reported only from Chutia Nagpur, which forms a north-eastern extension of the Dekhan, while the remaining seven have been met with both in Orissa and Chutia Nagpur but not in the Gangetic Plain.

[1] Memoirs of the Asiatic Society of Bengal, vol. 7, No. 4. "Introduction to the Study of the Fauna of an Island in the Chilka Lake," by Dr. N. Annandale.

The Sed Festival of Ancient Egypt.

AT a meeting of the Royal Anthropological Institute held on February 20, Mr. P. E. Newberry presented a paper on "The Sed Festival of Ancient Egypt." This was perhaps the most ancient of all the many Egyptian festivals: it was certainly the most important. There are representations of it on monuments from the beginning of the Ist Dynasty down to Ptolemaic times.

Various interpretations of the festival have been given, but none of them are entirely satisfactory. According to the Greek version of the Rosetta Stone, it was a festival marking a period of 30 years, but there are records of it being celebrated in the 2nd, 15th, 22nd, and 25th years of different kings' reigns. It appears to have been a repetition of the festivals of a coronation and its celebration seems to have procured for the king a new lease of life. It certainly had something to do with the king's assumption of responsibility for the protection of Egypt. It should be especially noted that the king's daughters take a prominent part in the festival. On the mace head of Narmer-Menes is the earliest representation of it: here there is a princess seated in a palanquin and behind her are three men in the act of running: this scene is also found in the Sed festivals of Neusere (Vth Dyn.), of Amenhotep III. (XVIIIth Dyn.), and of Osorkon (XXIInd Dyn.), although in the later examples young princesses standing replace the figure in the palanquin. This ceremony is probably the most primitive one of the Sed festival and represents, Mr. Newberry believes, a *race*, and a race for no less a prize than the Kingdom. Frazer in his "Lectures on the Early History of Kingship" (p. 260 *sq.*) notes that something, apparently the right to the hand of the princess and to the throne, has been determined by a race, and he quotes instances from classical and other sources. "Such a custom," he says, "appears to have prevailed among various peoples, though in practice it has degenerated into a mere form or pretence."

Although it is often assumed that the kingship was hereditary, in the male line—that the son regularly succeeded his father on the throne—it is certain that in Egypt the king claimed his right to the kingship, not because he was the son of his predecessor on the throne, but because he married the hereditary princess who might be the widow or daughter of his predecessor. It is obvious, there-

fore, that the marriage ceremony must have been a very important one in ancient Egypt. Egyptian women marry early in life, sometimes at 10 or 11, oftener at from 12 to 14 years of age. No doubt the same custom prevailed in ancient times. At 13, or even earlier, a girl may be a mother, and from 40 to 45 she becomes incapable of bearing children. When she becomes incapable of bearing children the husband often takes a new wife: this may perhaps explain why the Sed festival was called the 30 years' festival; for if a girl is married, say at 12, she ceases to be able to bear children at 42, just 30 years after her marriage, and her husband takes another wife.

If the hereditary princess predeceased her husband, then it must have been necessary for the king to marry again so as to retain the kingship: this would explain the fact that the Sed festival was sometimes celebrated in years earlier than the 30th year of a king's reign. It also explains why a king sometimes married his own eldest daughter. If the hereditary princess survived her husband, then Mr. Newberry's theory explains why she is sometimes married to her husband's successor. This theory would also give a reason for it being a kind of repetition of the king's coronation and for its procuring for the king a new lease of power.

There is yet another fact which suggests the theory that the Sed festival was a marriage festival. It was celebrated in a booth or tent (called *Sed*) raised high above the ground; and with Semitic peoples the tent plays a very important part in marriage ceremonial, as Robertson Smith notes in his "Kinship and Marriage," p. 198 ff.

Chemistry in Industry.[1]

NATURAL science — and in this connexion chemistry must be given a position of great prominence—is by far the most important dynamic factor in human progress. Notwithstanding its liability to abuse, its discoveries have, on the balance, made enormously for the greater good and greater happiness of the human race.

The direct utilisation by the State of the services of the professional chemist is a matter not only of immediate concern to chemists themselves, but also of high importance to the community at large, and it is one of the functions of the Institute of Chemistry to ensure that the relations between the appointing authorities and those who hold official chemical positions are of a satisfactory character. Unfortunately, some public bodies do not appear to be aware of the lengthy and expensive nature of the chemist's training or of the difficulties and responsibilities connected with his work, and consequently the advertised conditions of some public posts are not commensurate with the importance of the services demanded. There is a tendency on the part of local authorities to utilise the services of unqualified or imperfectly trained persons for carrying out what are regarded as simple routine processes, a practice against which the council of the Institute has protested vigorously on the ground that it constitutes a serious danger to the community and involves a waste of public money.

The disinterested zeal of the scientific worker is without parallel in the whole world, but it is not wise for any country to presume too much on this disinterestedness. Science is one of the greatest and freest of all givers, but it has a right to demand that recognition in the councils of the nation to which it is entitled. The indirect effect of proper State treatment is very great and the rulers of Germany know this well. A leading German industrial chemist said recently that notwithstanding Germany's position of virtual bankruptcy, the State, at the instigation of the commercial committee of the Reichstag, had come to the help of the great chemical and physical societies, particularly to that of the Kaiser Wilhelm Institute, and if the State could not continue financial aid, the German people themselves must give their last mark to maintain science.

Although the supply of qualified chemists exceeds, for the moment, the demand, there is no cause for serious alarm. The profession attracted a larger number of young men during the last four years than in any previous corresponding period. Notwithstanding the increased output from the colleges and the intense industrial and commercial depression, the new members of the profession are being steadily absorbed. This absorption may be taken as a definite indication that chemistry is more highly valued by the manufacturer than formerly, and that the leaders of industry and commerce are turning more and more to science to assist them in the solution of their various problems.

[1] From an address delivered to the Institute of Chemistry at the annual general meeting on March 1, by Mr. A. Chaston Chapman, F.R.S.

An Intestinal Parasite of Man.

WE understand that Sir Ronald Ross is engaged at the Ministry of Pensions in the investigation of *Giardi intestinalis*, often known as *Lamblia intestinalis*, which, of the three or four common flagellates inhabiting the intestine of man, has the greatest claim to pathogenicity. Moreover, it differs from the others in being an inhabitant of the duodenum and upper part of the small intestine instead of the large intestine. It is probably the first parasitic protozoan to have been observed, for, as Dobell has pointed out, the famous Dutch observer Leeuwenhoek saw it in his own stools so long ago as 1681. From that time down to the present day there has been much controversy as to the significance of its presence in the human intestine. Some regard it as a definitely harmful organism, while others believe that it does not damage its host in any way.

The frequent occurrence of the flagellate in enormous numbers in certain cases of mucous enteritis seems to suggest that it may sometimes be pathogenic, though, like parasitic amœbæ and bacteria which are known factors in disease, it often occurs in perfectly healthy individuals, who are to be regarded as carriers. American workers have brought forward evidence that *Giardia intestinalis* may invade the bile duct and gall bladder and cause irritation in these organs. Flagellates belonging to the same genus occur in domestic animals, such as dogs, cats, rats, and mice, but it appears that these are distinct from the human form, though Grassi and others believed that human beings became infected by ingesting the encysted forms of the flagellate which escape in large numbers in the dejecta of these animals. Careful experiments have, however, shown that it is not possible to infect animals with the human parasite, and slight morphological differences point to the existence of a number of distinct species.

Reproduction of the flagellate is by a complicated process of binary fission. The organism also becomes encysted in ovoid cysts within which division into two takes place. These cysts are found in the dejecta, and are responsible for the spread of infection. It is only during periods of diarrhœa that the free-swimming flagellates occur in the stool, so that infection of human beings is generally recognised by the discovery of the cysts. There is no known method of ridding a human being of infection, and if it is correct that the flagellate may sometimes damage its host, the outlook for these unfortunate individuals is not a bright one.

University and Educational Intelligence.

BELFAST.—At the recent meeting of the Senate of the Queen's University, it was announced that the bequest of 57,000*l.* from the late Henry Musgrave, a well-known benefactor of the University, had been paid. Of this sum 30,000*l.* is left to the absolute control of the Senate, to be used and applied for such purpose as the Senate shall consider necessary. Mr. Musgrave directed that 7000*l.* be invested, and the income applied towards paying an additional reader in connexion with the chair of physics. The sum of 20,000*l.* is to be invested, and the income applied in perpetuity for the promotion and encouragement of research in pathology, physiology, physics, biology, and chemistry. The income is to be applied in founding and maintaining studentships for promoting research in these subjects. Each studentship shall be held for one year, but if the electors are satisfied with the work of the student he may be elected for a second year but no longer. If at any time there shall not be any suitable candidate, or if in any year there be a surplus, such surplus shall form a fund out of which special grants may be made to graduates of the University engaged in research. The Senate has agreed that the annual value of the studentships shall be 200*l.*, and has appointed Prof. Ashworth, Prof. Lorraine Smith, Sir Joseph Larmor, and Prof. Collie, together with Prof. Symmers, Prof. Milroy, Prof. Morton, Prof. Small, and Prof. Stewart, to be the electors of the above studentships.

Mr. R. C. Johnson, Balliol College, Oxford, has been appointed lecturer in physics in succession to Dr. Gray, who resigned his appointment in December; Mr. S. P. Mercer, head of the Seed Testing Department of the Government of Northern Ireland, has been appointed lecturer in agricultural botany and plant diseases.

BRISTOL.—The Long Fox lecture will be delivered by Prof. F. Francis on Tuesday, March 27, at 5 o'clock. The subject will be "The Relation between Chemistry and Medicine."

The Coombe Memorial Scholarship, of the annual value of 60*l.* and tenable in the faculty of engineering of the University of Bristol, will be offered for competition for the first time this year. The scholarship has been established by the Engineering and the National Employers' Federations (West of England Association) as a memorial to a former president, and will be open to candidates who habitually reside within the area of the Association, which includes the counties of Gloucester, Somerset, Wilts, Devon, and Cornwall, as well as the city of Worcester and the towns of Hanley Castle, Malvern, Malvern Wells, Pershore, and Newport, Mon. The examination will be held at the Merchant Venturers' Technical College on Wednesday, July 4 next, and applications must be sent to Mr. A. Storey, director of the Association, not later than July 1.

CAMBRIDGE.—The Adams prize for an essay on "The Theory of the Tides" has been awarded to Mr. J. Proudman, Trinity College, director of the Liverpool University Tidal Institute. The essay submitted by Mr. H. Jeffreys, St. John's College, is highly commended.

Prof. H. A. Lorentz, of Haarlem University, will on May 15 deliver the Rede lecture on "Maxwell's Electromagnetic Theory."

On the conclusion of the last of the courses for naval officers held in the University since the termination of the war, the First Lord of the Admiralty has written to express the thanks of the Board of the Admiralty for the great service which the University has rendered the Navy. He expresses the hope that in some shape or other the intimate association between the two may still be kept alive for the mutual benefit of both.

Mr. M. B. R. Swann, University demonstrator in pathology, has been elected fellow and lecturer at Gonville and Caius College.

EDINBURGH.—On Thursday, March 1, the Right Hon. David Lloyd George delivered his address as Lord Rector to the students.

Mr. Lloyd George was afterwards entertained at lunch in the Union, and in replying to the toast of his health referred to the fact that seven of his colleagues in the late Government were graduates of Edinburgh. He dealt in an impressive manner with the relation of the universities to the War. He confessed that although he had known the part played by the universities in building up national efficiency, he never realised till the days of war what a national asset a great university was. He doubted very much whether the rich men of this country quite realised at the present moment what a national reserve a university is. After referring to the new kind of warfare developed by an enemy which was the most highly trained intellectual machine probably in the world, Mr. Lloyd George said the moment came when we called upon our universities, and they came to our rescue and poured out their trained minds—in the War Office, at the Admiralty, at the Ministry of Munitions—bringing the whole resources of their scientific knowledge, and, what was still more, knowing where to place their hands on people who had the training to enable them to take up the problems. He continued—"I don't know, I tell you now, what would have happened to us if we had not had the universities to fall back on in those dark days. I will tell you more. In the end our university brains beat theirs. War, you may say, is not what universities are for. I agree, but war is the great test of the nerve of a nation, of the muscle of a nation, of the heart of a nation. It tests every faculty of the human mind as well as the human body, and the test came; and in every particular, on land and sea, where scientific knowledge was required, where trained ingenuity was needed, we defeated the foe. That was due to the universities. Therefore I regard universities not merely as the great training-ground . . . I regard them as the fourth arm of defence for the security of this land."

Mr. Lloyd George warmly eulogised the services rendered by Principal Sir Alfred Ewing at the Intelligence Department, and stated that the work he did there gave information which ultimately brought America into the war.

LEEDS.—The Honorary Degree of Doctor of Laws was conferred upon Major the Right Hon. Edward Frederick Lindley Wood, president of the Board of Education, on March 5. Prof. Barbier, in presenting Mr. Wood, said: "The University desires to do honour to one who, the scion of a Yorkshire family of high distinction, is himself 'commended for the gifts that come from learning.' Mr. Edward Wood has won the respect of his fellow countrymen by the grave sincerity of his judgment. He holds an office of onerous responsibility in our public education. And by his unselfish generosity he has given to the transfer of an historic mansion the grace of a great benefaction to the city of Leeds."

LONDON.—Applications are invited by the senate for the Ramsay Memorial chair of chemical engineering tenable at University College. Particulars are obtainable from the Academic Registrar, University of London, South Kensington, S.W.7.

SHEFFIELD.—At the meeting of the Council on March 9 the following appointments were made: Mr. G. Grant Allan, to be assistant bacteriologist; and Mr. H. P. Lewis, to be assistant lecturer in mining geology.

Societies and Academies.

LONDON.

Royal Society, March 8.—A. B. **Wood**, H. E. **Browne**, and C. **Cochrane**: Determination of velocity of explosion-waves in sea-water; variation of velocity with temperature. An accurate determination of the velocity of explosion-waves in the sea gives:

(*a*) V = 4955·5 (±1) ft./sec., at 16·95 (±0·1)° C. and salinity 35 per cent.

(*b*) V = 4836 (±2) ft./sec., at 6·0 (±0·1)° C. and salinity 35·1 per cent.

(*c*) V = 4847 (±1·5) ft./sec., at 7·0 (±0·1)° C. and salinity 35·2 per cent.

In the new technique developed, it is unnecessary to know the exact position of charge relative to receivers. The results lead to a mean value of 10·9 ft./sec. per ° C. as the temperature-coefficient of velocity in the range 6° C. to 17° C. The following expression represents the velocity at any temperature t° C. within this range, and at any salinity S (parts per thousand):

$$V = 4627 + 13·7t - 0·12t^2 + 3·73S.$$

The salinity-coefficient is approximately 3 to 4 ft./sec. per 1 per cent. increase of salinity, the theoretical value being 3·73 ft./sec. per 1 per cent. No change was detected for charges varying in weight from 9 oz. to 300 lb. of explosive and no variation with depth. The coefficient of adiabatic compressibility of sea-water at 16·95° C. and 35 per cent. is $C_\rho = 42·744$ (±0·02) × 10^{-6}. Combining this with Ekman's value of C_θ, the ratio of the specific heats of sea-water under these conditions of temperature and salinity is $\gamma = 1·0094 \pm 0·0005$, in good agreement with 1·0090, deduced from thermo-dynamic data.—P. M. S. **Blackett**: The study of forked alpha-ray tracks. Forked alpha-ray tracks obtained by the Wilson condensation method were studied. The lengths of the tracks of the recoil atoms yield information concerning the relative ionisation due to different kinds of ionising particles, and of the average charge carried by them. Measurements of the angles between different parts of the tracks gave the masses of the recoil atoms in three particularly favourable cases.—A. **Egerton**: On the vapour pressure of lead.—I. The vapour pressure is measured by effusion of vapour at low pressure through a hole of measured area. Temperature is maintained constant by a selenium cell relay arrangement within 1/3° C. for many hours at about 800° C. Pressures were measured to 10^{-5} mm. The vapour pressure of ordinary lead between 1200-600° absolute is expressed by the equation $\log p = 7·908 - 9932/T$. The latent heat of vaporisation of lead (λ_0) is 47,000 ± 1000 cal. The chemical constant of lead is 1·84 ± 0·2, agreeing well with the theoretical value (1·853) obtained from the relation $3/2 \log M - C_0 = C$. The vapour pressures of lead and the uranium-lead isotope appear to differ by 2 per cent., but the result is rendered uncertain by an unexplained lowering of vapour pressure which lead undergoes on prolonged heating *in vacuo*.—A. C. **Egerton** and W. B. **Lee**: (1) Some density determinations. The Archimedes method of determining densities is rendered more accurate by utilising certain mobile and heavy organic liquids which avoid air bubbles and damping difficulties, and increase the weight of liquid displaced. Ethylene dibromide and carbon tetrachloride were employed with accuracy. A satisfactory sample of metal for density determination is prepared by filtering, casting, and heating *in vacuo*. The density of lead is 11·3437 at 20° C. The probable error of the nine determinations on three different samples is 1 part in 100,000. The maximum departure from the mean value for any single determination is less than 1 part in 12,000. A sample of uranium-lead would have an atomic weight of 206·26 from the density obtained. (2) Separation of isotopes of zinc. Two sets of distillations of pure zinc have been carried out in high vacuum, under conditions to obtain a slightly different concentration of the isotopes in the final residue of the final distillate. The samples are cast *in vacuo* and seeded with a particular kind of zinc. The first distillations gave a residue of slightly increased density, but the distillate possessed the same density as the original zinc. The second distillations gave a residue of increased density (about 1 part in 3700) and a distillate of decreased density (about 1 part in 3000). Determinations on seven samples of ordinary zinc give the density of zinc (prepared in the described way) as 7·1400 (the probable error being less than 1 part in 100,000). Flaws, allotropes, different physical conditions, and impurities are improbable. The amount of the separation agrees with Dempster's observations of isotopes of weights extending over six units (namely, 64-70), but is not so great as might be found for equal parts of 64 and of atoms of weights 66, 68, and 70.—E. **Hatschek** and P. C. L. **Thorne**: Metal sols in non-dissociating liquids. I.—Nickel in toluene and benzene. Very stable sols of nickel in a medium free from ions can be produced by decomposing nickel carbonyl dissolved in mixtures of toluene and benzene, containing a small amount of rubber, at 100° C. In the electric field the particles of disperse phase move to, and deposit on, *both* electrodes. Electrophoresis in fields of different strengths, all other factors being equal, shows that the amounts deposited are proportional to the first, or a lower, power of the potential gradient. Therefore positively and negatively charged particles are originally present in the sol. The sol resembles typical protected aqueous sols, inasmuch as it is coagulated by liquids which are not solvents for the protective colloid, *i.e.* rubber. The coagulum is only very imperfectly peptised again by rubber solvents, such as toluene or benzene.—H. **Hirata**: Constitution of the X-ray spectra belonging to the L series of the elements.

Zoological Society, February 6.—Sir S. F. Harmer, vice-president, in the chair.—Oldfield **Thomas**: (1) A new rock-kangaroo, *Petrogale godmani*, sp. n. It is like *P. assimilis*, but with a whitish tail, broader nasals, and larger secator. Its habitat is Black Mountain, near Cooktown, N. Queensland. (2) Skull of a pygmy fruit-bat from Sumatra. The generic name Æthalops is proposed.—C. A. Adair **Dighton**: Coat-colour in greyhounds.—E. G. **Boulenger**: The experiments of Dr. Kammerer and others upon amphibians and insects.—E. Leonard **Gill**: The Permian fishes of the genus Acentrophorus.—Charles F. **Sonntag**: On the vagus and sympathetic nerves of the terrestrial carnivora.—E. P. **Allis**: The postorbital articulation of the palato-quadrate with the neurocranium in the Cœlacanthidæ.—G. S. **Giglioli**: On the linguatulid arachnid, *Raillietiella furcocerca* (Diesing, 1835), Sambon, 1922.—Mrs. Rita **Markbreiter**: Some Microfilaria found in the blood of birds dying in the Zoological Gardens, 1920–1922.

February 20.—Dr. A. Smith Woodward, vice-president, in the chair.—D. **Seth-Smith**: Sexual display of the Magnificent Bird-of-Paradise (*Diphyllodes magnifica hunsteini*).—Einar **Lönnberg**: Remarks on some palearctic bears.—E. W. **Shann**: The embryonic development of the porbeagle-shark, *Lamna cornubica*.—Robert **Gurney**: Some notes on *Leander longirostris*, M.-Edwards, and other British prawns.

Faraday Society, February 19.—Sir Robert Robertson, president, in the chair.—A. W. **Porter** and J. J. **Hedges**: The law of distribution of particles in colloidal suspensions with special reference to Perrin's investigations. Pt. ii. The behaviour of particles specifically lighter than the medium has been examined in regard to distribution with height, using for the purpose emulsions of paraffin in water. The change of concentration occurs only at the bottom of the containing vessel. There is an increase of concentration with height reckoned from the bottom. A type of curve is suggested which fits closely the experimental results.—D. B. **Macleod**: On a relation between surface tension and density. The empirical relation $\gamma/(\rho_l-\rho_v)^4=C$, where γ is the surface tension at any temperature, ρ_l and ρ_v the densities of the liquid and the vapour at the same temperature and C is a constant for each liquid, fits the experimental figures with remarkable accuracy for temperatures ranging from the melting-point to the critical temperature.—D. B. **Macleod**: (1) On a relation between the viscosity of a liquid and its coefficient of expansion. If x_0 be the volume of the free space in 1 c.cm. of a liquid at 0° C. and $1-x_0$ the volume occupied by the molecules, it is assumed that at a temperature t° C. the volume of the free space is $x_0+\alpha t+\beta t^2+\gamma t^3$—the volume of the molecules remaining constant. The viscosity of liquids is expressed as a function of the free space, thus $\eta\mu x_t^A=C$. For normal liquids A is nearly unity. For associated liquids it has a higher value. The values obtained for the free space for various liquids at their boiling-points are practically constant and of the order required by Van der Waal's theory. An expression is given for the viscosity of liquids at different temperatures and pressures. (2) On the viscosity of liquid mixtures showing maxima. The viscosity of liquid mixtures is a function of the free space of the constituents and of the mixture. In the case of liquid mixtures showing a maximum, the increase of viscosity is due mainly to the increase of density, which in turn is due to the chemical affinity between the constituents. It is probable that complexes which are formed further reduce the free space and consequently increase the viscosity.—F. H. **Jeffery**: Electrolysis with an aluminium anode, the anolyte being (1) solutions of sodium nitrite, (2) solutions of potassium oxalate. With solutions of sodium nitrite probably the primary product of reaction at the anode is aluminium nitrite which is hydrolysed rapidly to hydrated aluminium oxide and nitrous acid, the latter giving rise to nitric oxide and nitric acid. With solutions of potassium oxalate the product of reaction at the anode is a complex anion derived from aluminium. The salt $K_3\{Al(C_2O_4)_3\}\,.\,3H_2O$ can be derived from the anolytes after electrolysis. It is probable that the salt is a true complex salt comparable with potassium chromioxalate, and if this be true, the alumini-oxalate complex can be represented in three dimensions just as Werner represented the chromioxalate. The isolation of a complex salt from an anolyte does not imply necessarily that the constitution of the anionic part of this salt is identical with that of the complex anion present in the anolyte after electrolysis.—Maurice **Cook**: Crystal growth in cadmium. Evidence has been obtained that unworked crystals can grow under certain conditions. The usual methods of preparing metallic specimens for microscopic examination are useless, since the specimen cannot be regarded as unworked after it has been sawn off the original, ground, and polished. In these experiments the metal is cooled in such a way as to be free from the stresses usually set up during solidification. The results obtained indicate that during annealing considerable crystal growth has taken place. Irregularity in the shape of the grains is probably a factor greatly facilitating crystal growth.—S. D. **Muzaffar**: Electric potential of antimony-lead alloys. Measurements of the electric potential of the antimony-lead alloys were made by means of a quadrant electrometer against a calomel electrode in N KOH, N $Pb(NO_3)_2$, and tartar emetic with tartaric acid solutions. The results reveal an identity of potential up to 98 per cent. antimony with that of lead, which show the formation of no solid solution and no chemical compound between the two metals.

Royal Microscopical Society, February 21.—Prof. F. J. Cheshire, president, in the chair.—Sir W. M. **Bayliss**: Colloids and staining. The histologist is concerned with the staining of particles, large or small, sometimes present in the living cell, sometimes formed by fixing agents. The process is a complex one; but, as would be expected from the heterogeneous nature of the systems concerned, adsorption is the chief factor, especially in its electrical aspect; chemical combination seems to be of less importance. Thus, surfaces with a positive charge take negative ("acidic") dyes, those with negative charge take "basic" or positive dyes. The degree depends on the magnitude of the charge, as shown by the effect of electrolytes, alcohol, heat, isoelectric point, etc. The removal of the amino groups from proteins has no effect on the process. Adsorption can be distinguished from chemical combination in certain cases, such as silk dyed with the acid of Congo-red. The fixation of stains by heat is difficult to explain. The action of mordants is also obscure; chemical combination as "lakes" is only a partial explanation, since these are stated to be resistant to acids. Differentiation appears usually to be a process of colloidal dispersion of the "lake." In a few cases, as the staining of fat by Soudan III., partition in accordance with solubility is the main factor. A. **Mallock**: The resolving power and definition of optical instruments. Resolving power is taken as indicating the least distance (angular or linear) at which two points can be seen as separate in the field of the instrument; definition is the ratio of that area of the field over which the resolving power is maintained to the whole area, or, shortly, the dimensions of the least objects appreciable and the range over which the appreciability extends. Optical images are formed when and where a number of paths from one point to another have the same optical length, in which case either point may be considered as the image of the other. By optical length is meant the length measured in wave-lengths in the medium through which the path proceeds. The constancy of this length causes all the waves emanating from one of the points to arrive at the other in the same phase, and this condition may be used to determine the form of the reflecting or refracting surfaces required to make one point the image of another. Resolving power depends on the rapidity with which the length of the optical path varies as the distance from the geometrical focus is increased: the more rapid the variation the greater is the concentration of the light and the smaller the luminous area which forms the image of a point. For telescopes where the angular aperture of the lens is small the variation is proportional to the diameter of the object glass, and a perfect lens one inch in diameter should have a resolving power of 4 in. of arc. For microscopes where the angular aperture of the lens is large the least appreciable distance is about $\lambda/2$ or 1/100,000 in. with ordinary light. Test plates for microscope objectives consist of groups of fine lines ruled on films of anilin colour, the thickness of which is only a small fraction of a wave-length of light.

PARIS.

Academy of Sciences, February 19.—M. Albin Haller in the chair.—G. **Urbain**: Celtium, element of atomic number 72. A discussion as to the priority of Coster and Hevesy. The author cites the earlier work of Dauvillier and himself, and concludes that Coster and Hevesy were not the discoverers of element 72, but have only found a material in which it is present in a relatively high proportion. The author claims that the name celtium has priority over hafnium for this element.—J. L. **Breton**: Spark-gaps in which the spark in a gaseous dielectric is deflected by a strong air current. Two types of spark-gap are described. The simpler of the two consists of a conducting disc of metal or graphite rotating with a high velocity in a hermetically closed cylinder filled with coal gas or the vapour of alcohol. The sparks play between this disc and two graphite electrodes. Long uninterrupted working is secured by water-cooling or by a fan. The apparatus has been successfully applied to the working of a high-frequency-induction furnace.—Jules **Andrade**: Isochronism and quadratic friction.—Georges **Friedel**: Cholesteric bodies.—C. **Sauvageau**: The prolonged quiescent state of an ephemeral Alga (Mesogloia).—M. W. C. Brögger was elected a foreign associate in the place of the late M. Schwendener.—A. **Myller**: Systems of curves on a surface and the parallelism of M. Levi-Cività.—M. **Juvet**: A generalisation of Jacobi's theorem.—M. **Malaval**: Permanent deformations by extension and compression.—M. **Mesnager**: Observations on the preceding note.—P. **Dumanois**: An aerodynamical arrangement for testing motors. The usual fan resistance does not permit of continuous variation. The author encloses the fan in a cylindrical drum closed by two plane parallel walls, one of which is constructed of radiating shutters. By partially opening the shutters, when fixed to a 12 h.p. motor, the number of turns per minute can be varied between 950 and 1470, a sufficient variation for practical conditions of use.—M. **Rateau**: Remarks on the preceding communication. M. Dumanois' apparatus has advantages over the Froude brake.—A. **Weinstein**: The unicity of sliding movements.—Charles **Bohlin**: The autologous series belonging to the problems of two and three bodies.—Ernest **Pasquier**: A simple expression of the acceleration of mercury in the case of the problem of two bodies, taking into consideration the movement of the perihelion of the planet.—Thadée **Peczalski**: The relation between Young's modulus and the ratio of density to atomic mass. The relation $E=B(\delta/M)^3$ is deduced, in which E is Young's modulus, δ is the density, M the atomic mass, and B a constant (8×10^5 kilograms per sq. mm.). The calculated and experimental values are compared for nine metals.—A. **Marcelin**: Superficial fluids. The unlimited extension of oleic acid. A study of the "superficial pressure" exerted by a thin layer of oleic acid on water. When the layer of oleic acid is one molecule thick the acid may be regarded as being in an intermediate state between the free and dissolved states, to which the name of "superficial solution" is given.—St. **Procopiu**: The appearance of the flame, arc and spark lines in the arc-spectra of metals in a vacuum.—Albert **Portevin** and François **Le Chatelier**: A phenomenon observed during the test by extension of alloys in course of transformation. The peculiarity observed was confined to aluminium alloys of the duralumin type with or without the addition of other metals (manganese, zinc). The elongation of the test pieces, instead of increasing continuously with the pull, progressed by repeated oscillations of an amplitude amounting to 4 per cent. of the load and with a frequency of several oscillations per second. The phenomenon attained its maximum amplitude immediately after tempering.—A. **Bigot**: The action of heat on kaolins, clays, etc. Black pottery. A study of the black pottery from the Bouchets Cave (Ardèche), from Basutoland, and of Etruscan black vessels.—André **Brochet**: The hydrogenation and dehydrogenation of castor oil and its derivatives. Castor oil with active nickel was treated with hydrogen at 150° C. under pressure. The pressure showed a series of oscillations which can be interpreted by assuming a series of hydrogenations and dehydrogenations. The fully hydrogenated product gave off hydrogen on heating with nickel to about 280°, but the product finally obtained did not correspond with the original oil.—René **Locquin** and Sung **Wouseng**: the hydration of the dialkylethinylcarbinols and the preparation of the α-hydroxymethyl ketones. Tertiary acetylenic alcohols of the type $RR.C(OH).C\equiv CH$ are readily converted into the ketones $PR.C(OH).CO.CH_3$ by Denigès' reagent (acid sulphate of mercury). Details of the method are given and a description of five ketones prepared by this general method.—Henry **Joly**: Stratigraphical observations on the Oxfordian and Lusitanian at certain points in the Celtiberic chain (Spain).—Léon **Bertrand** and Antonin **Lanquine**: The large Provençal sheets of Audibergue and Cheiron (Maritime Alps).—E. **Schnæbelé**: The present structure of the primary Vosges. The application to the whole of the Vosges of observations made especially to the north of the valley of Villé.—L. **Giraux**: The geological position of the neolithic workshops of the forest of Montmorency.—J. **Beauverie**: The relations existing between the development of wheat rust and climate. The sharp contrast between the climatic conditions in 1921 and 1922 showed that *Puccinia triticina* is especially the rust of dry seasons and *P. graminis* is the rust of wet seasons, the latter doing the most damage from the point of view of yield of grain.—M. **Rose**, J. **Dragoiu**, and F. **Vlès**: The reversibility of the phenomena of arrest by lowering the *p*H in the evolution of the eggs of the sea urchin.—M. and Mme. G. **Villedieu**.—The action of insoluble oxides on the mildew of potato (*Phytophthora infestans*). It is generally admitted that for a substance to act on a living organism it must first be rendered soluble. Experiments on the toxic action of the insoluble oxides of various metals (magnesium, cadmium, nickel, cobalt, zinc, copper, mercury) on the conidia of potato mildew are in direct contradiction with this hypothesis.—R. **Herpin**: Comparison between the sexual behaviour of some nereidians from the coasts of the Channel.—Ch. **Gravier**: Remarks on the preceding communication.—Auguste **Lumière**: The possibility of realising intestinal disinfection. An account of some experiments with sodium argentothioglycerine sulphonate, $AgS.CH_2.CH(OH).CH_2.O.SO_3Na$. Experiments on a dog showed that while a dose of 1 gm. of benzonaphthol per day had no effect on the number of organisms in the fæcal matter, the administration of the same weight of the silver compound sterilised the intestine in four days.

Diary of Societies.

SATURDAY, MARCH 17.

BRITISH MYCOLOGICAL SOCIETY (in Botany Department, University College), at 11.—Rev. P. J. Alexander: An Ecological and Phenological Account of the Mycetozoa of Surrey.—Miss M. H. Carré, Dr. A. S. Horne, Miss H. M. Judd, and Mrs. H. S. Williamson: Eidamia.—Dr. J. S. B. Elliott and Miss O. Stansfield: The Life History of *Polythrincium Trifolii* Kunze.—J. Ramsbottom: (1) The Correspondence of Berkeley and Broome; (2) Mycology at the British Empire Exhibition (1924).

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (5).

MONDAY, MARCH 19.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge, Kensington Gore), at 5.—Col. M. N. MacLeod, Squadron-Leader F. C. V. Laws, and Major Griffiths: Recent Developments of Air Photo-topography.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—H. T. Young and others: Discussion on the Need for Co-operation between Electrical Manufacturers and Contractors.

INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Section), at 7.—R. C. Bond: The Walschaert Locomotive Valve-gear.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—G. E. S. Streatfeild: The Hammersmith Housing Scheme.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Miss H. D. Oakeley and others: Discussion on Prof. Wildon Carr's A Theory of Monads.

ROYAL SOCIETY OF ARTS, at 8.—J. E. Sears, jun.: Accurate Length Measurement (3) (Cantor Lecture).

CHEMICAL INDUSTRY CLUB (at Whitehall Court), at 8.

TUESDAY, MARCH 20.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lecture: Diseases of the Prehistoric Britons.

ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. A. J. Hall: Encephalitis Lethargica (Epidemic Encephalitis) (2) (Lumleian Lecture)

ROYAL STATISTICAL SOCIETY, at 5.15.

NEWCOMEN SOCIETY (at Prince Henry's Room, 17 Fleet Street), at 5.30.—D. Brownlie: The Early History of the Gas Process.

INSTITUTE OF TRANSPORT (at Institution of Electrical Engineers), at 5.30.—Lecture on Town-planning and Re-modelling in Relation to Traffic.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Sushil Ch. Sarkar: A Comparative Study of the Buccal Glands and Teeth of Opisthoglyph Snakes, and a Discussion on the Evolution of the Order from Aglypha.—O. Thomas and M. A. C. Hinton: The Mammals obtained in Darfur by the Lynes-Lowe Expedition.—R. I. Pocock: (1) The External Characters of Elaphurus, Hydropotes, Pudu, and other Cervidæ; (2) The Classification of the Sciuridæ.

INSTITUTION OF CIVIL ENGINEERS, at 6.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—J. Lamb: Operation of the Marine Diesel Engine—Cylinders and Pistons.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—W. F. A. Ermen: The Preparation of Metol and its Homologues.

MEDICO-LEGAL SOCIETY (at Medical Society of London), at 8.30.—Dr. H. A. Burridge and others: Discussion on State Effort to rescue Drug Victims, with special reference to the Dangerous Drugs Act.

WEDNESDAY, MARCH 21.

INSTITUTION OF NAVAL ARCHITECTS (at Royal United Service Institution), at 11.—Sir Eustace T. d'Eyncourt and J. H. Narbeth: A Proposed Aircraft-carrying Mail Steamer.—Sir John E. Thornycroft and Lieut. Bremner: Coastal Motor Boats in War-time.—At 3.—A. C. F. Henderson: Remarks on Some of the Present-day Problems in the Design of Ships.

WOMEN'S ENGINEERING SOCIETY (at 26 George Street, W.1), at 6.15.—Dr. R. S. Hutton: Scientific Studies of Manual Work (Motion Study and Vocational Training).

ROYAL MICROSCOPICAL SOCIETY (Industrial Applications Section), at 7.—E. Hatschek: The Standard Methods of Ultra-microscopy.—Dr. A. C. Thaysen: The Destruction of Cotton and other Fabrics by Bacteria, and the Importance of the Microscope in the Study of this Destruction.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—G. M. B. Dobson: The Characteristics of the Atmosphere up to 200 km., as obtained from Observations of Meteors.

ROYAL SOCIETY OF ARTS, at 8.—Dr. F. W. Edridge-Green: Some Curious Phenomena of Vision and their Practical Importance.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

ROYAL SOCIETY OF MEDICINE (Social Evening), at 9.—Dr. H. C. Cameron: The Mystery of Lord Byron's Lameness.

THURSDAY, MARCH 22.

INSTITUTION OF NAVAL ARCHITECTS (at Royal United Service Institution), at 11.—The Hon. Sir Charles A. Parsons, S. S. Cook, and H. M. Duncan: Mechanical Gearing.—W. Le Roy Emmet: Electric Ship Propulsion. At 3.—G. S. Baker and W. C. S. Wigley: Model Screw Propeller Experiments with Mercantile Ship Forms. At 8.—K. C. Barnaby: The Powering of Motor Ships.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lt.-Col. E. F. Strange: Japanese and Chinese Lacquer (2).

ROYAL SOCIETY, at 4.30.—G. Hewett: The Dusuns of British North Borneo.—L. T. Hogben and F. R. Winton: The Pigmentary Effector System. III. Colour Response in the Hypophysectomised Frog.—H. R. Hewer: Studies on Amphibian Colour Change.—J. Walton: On Rhexoxylon, Bancroft. A Triassic Genus of Plants exhibiting a Liane-type of Vascular Organisation.—Margaret Tribe: The Development of the Hepatic Venous System and the Postcaval Vein in the Marsupialia.—J. Gray: The Mechanism of Ciliary Movement. III. The Effect of Temperature.—E. Ponder: The Inhibitory Effect of Blood Serum on Hæmolysis.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. A. J. Hall: Encephalitis Lethargica (Epidemic Encephalitis) (3) (Lumleian Lecture).

FELLOWSHIP OF MEDICINE (at Royal Society of Medicine), at 5.30.—Dr. H. W. Barber: The Investigation of certain Diseases of the Skin in the Light of Recent Research.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. H. C. Miller: The New Discipline.

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—Dr. L. C. Martin: Surveying and Nautical Instruments from an Historical Standpoint.

CAMERA CLUB, at 8.15.—T. Bell: Portraiture.

ROYAL SOCIETY OF MEDICINE (Urology Section), at 8.30.—S. Joly: Diverticulum of the Bladder with special reference to Operative Treatment.

FRIDAY, MARCH 23.

INSTITUTION OF NAVAL ARCHITECTS (at Royal United Service Institution), at 11.—Prof. T. B. Abell: The Behaviour of Stiffened Thin Plating under Water Pressure.—Dr. J. Montgomerie: Further Experiments on Large-size Riveted Joints.—J. Anderson: The Influence of Form upon the Stability and Propulsion of Passenger Ships.—At 3.—W. Thomson: The Effect of Variations in Loading on Longitudinal Structural Stresses in Ships.—E. V. Telfer: Graphical Trim Calculation and a Trim Nomogram.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Theatre, Imperial College of Science and Technology), at 2.30.—Prof. J. H. Priestley: The Causal Anatomy of the Potato Tuber.—E. H. Richards: Cellulose Decomposition: its Control and Applications.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5.—Dr. W. J. H. Moll: A Moving-coil Galvanometer of Rapid Indication.—Dr. W. J. H. Moll: A Thermopile for measuring Radiation.—Capt. C. W. Hume: Aberration and the Doppler Effect on the Theory of Relativity;—and the following Experimental Demonstrations:—C. R. Darling and the Hon. F. W. Stopford: The Production of E.M.F.'s by Heating Junctions of Single Metals.—R. H. Humphry: The Double Refraction due to Motion in a Vanadium Pentoxide Sol, and some Applications.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—R. J. Siddall: History and Development of the Underground Railway.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—F. G. Newmarch: A Tramp through Corsica.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir Ernest Rutherford: Life History of an Alpha Particle from Radium.

SATURDAY, MARCH 24.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Ernest Rutherford: Atomic Projectiles and their Properties (6).

BRITISH PSYCHOLOGICAL SOCIETY (at King's College), at 3.15.—Miss Mary Sturt: The Estimate of Duration.

PUBLIC LECTURES.

SATURDAY, MARCH 17.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. A. Abram: Travelling in the Middle Ages.

TUESDAY, MARCH 20.

SCHOOL OF ORIENTAL STUDIES, at 5.—Sheikh Abd el Razek: The Study in Europe of Moslem Civilisation.

WEDNESDAY, MARCH 21.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 5.—Lord Sumner of Ibstone: The Public and the Architect.

SATURDAY, MARCH 24.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr. W. A. Cunnington: The Natural History of Lobsters and Prawns.

BEDFORD COLLEGE FOR WOMEN
(UNIVERSITY OF LONDON).

POST-GRADUATE SCHOLARSHIP.

The Council of Bedford College for Women invite applications for a POST-GRADUATE SCHOLARSHIP in SCIENCE to be awarded in June 1923. Open to graduates of Bedford College only. Value £125 a year for two years.

For further information apply to the SECRETARY, Bedford College, Regent's Park, N.W.1.

PRIFYSGOL CYMRU.
UNIVERSITY OF WALES.

THREE FELLOWSHIPS, tenable for two years, may be awarded in 1923 to Graduates of the University of Wales. The value of each Fellowship will be £200 per annum. Applications from Candidates for the Fellowships must be received before June 1, 1923, by the REGISTRAR, University Registry, Cathays Park, Cardiff, from whom further information with regard to the Fellowships may be obtained.

H.M. SIGNAL SCHOOL,
R.N. BARRACKS, PORTSMOUTH.

Applications are invited for two vacancies for ENGINEERS, GRADE II., in the LABORATORY SECTION of the above School. The duties concern the development of Wireless Telegraphy, etc., for Naval purposes. Preference given to candidates possessing an Honours Degree in Physics or Electrical Engineering.

The salary scale is £150, rising by annual increments of £10 to £300 per annum, plus bonus based on the average cost of living figure. The minimum pay plus bonus at present is £244 per annum.

The appointments are not established and the Federated Universities Superannuation Scheme is applicable.

Applications giving full particulars of the candidate's experience, War Service, etc., should be addressed to THE SECRETARY OF THE ADMIRALTY (C.E.), Admiralty, S.W.1, from whom further particulars of the duties, etc., can be obtained.

BEDFORD COLLEGE FOR WOMEN
(UNIVERSITY OF LONDON).

The Council of Bedford College invite applications for the posts of (i) DEMONSTRATOR in ORGANIC CHEMISTRY; (ii) DEMONSTRATOR in INORGANIC and PHYSICAL CHEMISTRY; (iii) PART-TIME ASSISTANT in LATIN.

Candidates must have an Honours Degree or its equivalent.

Applications must be received not later than Saturday, April 28.

For all particulars apply to the SECRETARY, Bedford College, Regent's Park, N.W.1.

UNIVERSITY OF LONDON.

The Senate invite applications for the following UNIVERSITY READERSHIPS tenable at Bedford College:

READERSHIP in GEOGRAPHY, salary £700 a year.
READERSHIP in MATHEMATICS, salary £500 a year.

Applications (12 copies) for either post must be received not later than first post on April 13, 1923, by the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7, from whom further particulars may be obtained.

UNIVERSITY OF LONDON.

The Senate invite applications for the RAMSAY MEMORIAL CHAIR of CHEMICAL ENGINEERING tenable at University College. Full particulars may be obtained from the ACADEMIC REGISTRAR, University of London, South Kensington, London, S.W.7.

UNIVERSITY OF LONDON, KING'S COLLEGE.

The Delegacy require the services of a DEMONSTRATOR in BOTANY (man). Salary £250 per annum. The duties will commence in April. Opportunities will be given for research work.

Applications, with two copies of not more than three recent testimonials, should be received not later than April 10 by the SECRETARY, King's College, Strand, W.C.2, from whom further particulars may be obtained.

X-RAY ENGINEER requires position.

Considerable practical experience and good knowledge of theory; also scientific side of X-Ray work, including physics and mathematics. Box 65. c/o NATURE Office.

MUSEUM ASSISTANT; Youth 18, seeks

post. Camb. Senr. 2nd Class Honours, Matric. Exempn., Entomologist, Illustrations line and colour. Natural History. Prehistoric Man, References. K. WILKINSON, 64 Longstone Road, Eastbourne.

RESEARCH APPOINTMENT UNDER THE MINES DEPARTMENT.

The Secretary for Mines invites applications for a POST under the Safety in Mines Research Board. The appointment is a whole-time one and the provisions of the Federated Universities Superannuation Scheme apply. The salary, including superannuation contributions and all other emoluments, will depend upon the qualifications of the candidate selected and will not exceed £2000 per annum.

Candidates must possess high general scientific qualifications and experience in engineering, and a knowledge of coal mining will be a recommendation. The holder of the appointment will be required to advise the Board on questions of research in regard to the safety problems of coal-mining, to prepare programmes of research, to organise and superintend research work, and generally to co-ordinate the scientific work of the Board. It will also be his duty to prepare a scheme for the centralisation of the research work of the Board in a permanent Station.

Applications, which should be addressed to the UNDER SECRETARY FOR MINES, Mines Department, Dean Stanley Street, London, S.W.1, should reach that address not later than April 30, 1923.

March 13, 1923.

BRIGHTON SUMMER SCHOOL, 1923.

Director—Prof. T. H. PEAR, M.A., B.Sc.

In the Municipal Training College, on the Front, from July 30 to August 11 inclusive.

Courses in General Psychology, Experimental Psychology, History of Education (suitable for Diploma students), etc.

Hostel accommodation for men and women at College Hostels on the Front.

Further information from HONORARY SECRETARY, 8 Eastern Terrace, Brighton.

TUITION BY CORRESPONDENCE

Rapid preparation by highly qualified tutors for

MATRICULATION,
Intermediate and Final B.A. and B.Sc.,
OXFORD AND CAMBRIDGE LOCALS.

Single subjects may be taken:—Latin, Greek, Hebrew, French, Mathematics, Chemistry, Logic, etc. For terms address—

Mr. J. CHARLESTON, B.A. (Hons. Oxon. & Lond.),
14 Elsham Road, Kensington, W.14.

TO LET—for July and August—Plas Gwyn,

Bangor, overlooking Snowdon and Straits, large garden (tennis, poultry kept). Prof. BRYAN.

PHILOSOPHICAL MAGAZINE—For Sale,

eleven years, complete 1904 to 1914 inclusive, unbound. What offers? J. WILDMAN, 16 Shadwell Road, Portsmouth.

FOR SALE—NATURE, Dec. 1919 to date.

Unbound. £3. WILLIS, 37 Woodville Road, Golders Green, N.W.11.

ACCURATE CHEMICAL THERMOMETERS.—

110° C., 150° C., 250° F., 300° F., 2s.; 200° C., 2s. 6d.; 360° C., 400° F. 3s.; 500° C., gasfilled, special glass, 10s. Beckmann Thermometers with Auxiliary Scale, $\frac{1}{100}$° C., 22s. 6d. each.—CHEELD, Chesham.

WE SPECIALISE IN THE QUANTITY PRODUCTION OF OPTICAL AND MECHANICAL PARTS ON AN INTERCHANGEABLE BASIS. WE INVITE ENQUIRIES.

Labour and Science in Industry.

THE statement issued by the Trade Union Congress on February 19 entitled "The Attack on Labour Standards" calls for notice from those interested in the scientific organisation of industry. It is stated quite truly that "During the last 150 years industrial conditions have been revolutionised. Labour-saving devices have been introduced: steam and electric power have been developed, and the increased productive capacity of industry following innumerable inventions and scientific discoveries has enabled those who work by hand and brain to increase enormously their output." But if this increase in mechanical power is to be labour-saving, it must not, they go on to say, be at the expense of those who labour, and they have some fear that an attempt is being made "to utilise the present 'slump' for the purpose of degrading conditions of employment to the lowest possible point." In particular it is claimed that a reduction in the hours of labour is the only means of enabling the workers to share in the triumphs of civilisation and industrial peace, and that a firm front must be maintained on that point.

It would be impossible in a short article, and unsuitable in these columns, to enter on a discussion of the detailed questions involved in various industries at the present day; but the general question is one of the highest moment. Seeing that the application of science to industry has transformed society in the period referred to, and has indirectly affected politics, art, education—in fact every side of Western life—it behoves us to consider with the utmost care how far the mass of the workers has benefited by the change. By this it must ultimately be judged, for whatever may be the eternal value or eternal permanence of knowledge in itself, as soon as we apply it to the conditions of our life, it must be judged by the effects on the whole people and not on the few. As a human being, enjoying the products of industry, the happiness of the manual worker has an absolutely equal claim to moral or legal consideration with that of those who direct or organise his work.

This will scarcely be questioned nowadays on the employing side. Are not the "workers" on their side now ready to agree that, so far as we can judge in so difficult a matter, since the Trade Union action and legislation of the last three-quarters of a century, the conditions of the working-class are both happier, more intelligent, and more humane than they were before Watt invented the steam-engine?

But, it will be said, is not the betterment, if real, due not to science, but to legislation and other action necessitated by the evils which the industrial

revolution had produced? Above all, have the "workers" received a fair share in the increased products?

On the latter point a decision commanding universal assent is impossible. There is no absolute standard of justice in such affairs. If we can be satisfied on the general question, that the condition of the workers has been appreciably improved by the applications of science to industry and life, it would be unreasonable to seek a mathematical proportion. Can we? Immediately after the introduction of big machines and factory production, we certainly could not. The herding together of crowds of poor people in hideous, hastily constructed, and insanitary town-dwellings was a monstrous evil. Even now these conditions too largely persist to allow a very roseate picture to be drawn. But, on the other hand, so much has been done to ameliorate them that it would be equally untrue to paint quite so black a picture as may be heard described from Labour platforms. Life has been transferred from country to town for the mass of our people, and that has its inevitable drawbacks. But it is not on the whole an unhappy or degraded life. Houses have been, and are being, vastly improved. Hours of labour have been reduced, and there is not the slightest prospect of their return to the condition of the early factory years. Facilities for education and enjoyment have been vastly increased, or rather newly created. Health is remarkably improved.

One result of the change in industry due to science is seldom noted in these discussions, and yet it is one of the most important. Mass production and scientific machinery have between them thrown up a large new class of men intermediate between the manual workers and the capitalist director. This class—the foreman, the shop-steward, the manager, the man with exceptional organising or mechanical ability who invents and sets up on his own account—is the most characteristic human product of the industrial revolution and one of the weightiest factors in modern society. Those estimating the share taken by "Labour" in the fruits of scientific industry cannot omit this, which is the best paid section and nearest to the mainspring. Moreover, in general we may note that those industries which have absorbed most brains in their development, notably engineering, also pay the highest wages. Agriculture, which has up to the present remained most primitive, pays the lowest.

The application of science to industry does not appear, therefore, to carry with it the wholesale degradation of the working-class as is sometimes contended, though the great mass who do purely mechanical work are rightly the chief concern of the social reformers and the Trade Union Congress. F. S. M.

An Antarctic Saga.

The Worst Journey in the World: Antarctic, 1910–1913. By Apsley Cherry-Garrard. (In 2 vols.) Vol. 1. Pp. lxiv + 300 + 4 + 30 plates + 4 maps. Vol. 2. Pp. viii + 301-585 + 28 plates + 1 map. (London, Bombay, and Sydney: Constable and Co., Ltd., 1922.) 63*s*. net.

THIS is the sixth book to give the story, or part of the story, of Capt. Scott's last expedition, and it is in some ways the most remarkable of them all. Mr. Cherry-Garrard took part in three of the worst journeys ever made in the Antarctic or anywhere else, and the iron of his sufferings has entered into his soul and imparted a ferric quality to his recollections. He writes often with a forceful epigrammatic directness that makes one gasp; again he falls back into pages of rather heavy going, for his quotations from the other books on the expedition are very numerous, albeit they are well chosen. The very first paragraph of the preface sets the keynote of simulated cynicism and paradox.

"This post-war business is inartistic, for it is seldom that any one does anything well for the sake of doing it well; and it is un-Christian, if you value Christianity, for men are out to hurt and not to help—can you wonder when the Ten Commandments were hurled straight from the pulpit through good stained glass. It is all very interesting and uncomfortable, and it has been a great relief to wander back in one's thoughts and correspondence and personal dealings to an age in geological time, so many hundred years ago, when we were artistic Christians, doing our jobs as well as we were able just because we wished to do them well, helping one another with all our strength, and (I speak with personal humility) living a life of co-operation in the face of hardships and dangers which has seldom been surpassed."

This prepares us for the last sentence in the preface, which in turn illuminates the literary landscape of these volumes:

"My own writing is my own despair, but it is better than it was, and this is directly due to Mr. and Mrs. Bernard Shaw. At the age of thirty-five I am delighted to acknowledge that my education has at last begun."

An author possessed of so humble and hopeful a disposition should not take it amiss if a critic tries to help by suggestions of improvement as well as by hearty recognition of exceptional candour and artistic power.

To begin with, the historical introduction detracts from the value of the book, of which it occupies sixty-four pages. It ought to have been much shorter and focussed more directly on McMurdo Sound. Unfortunately, Mr. Cherry-Garrard went direct to Cook's "Second Voyage" and neglected to check his extracts in proof, otherwise he would not speak of "*sus*pissated

juice," nor would he have quoted a longitude as "2° East" without adding Cook's essential words "of the Cape of Good Hope." On the other hand, he omitted to consult the *Challenger* "Narrative," but took from some uncited source the surprising statement that the *Challenger* "spent three weeks within the Antarctic Circle," the actual time having been more nearly three hours. Later history as summarised by Mr. Cherry-Garrard also requires revision. Borchgrevink should have been mentioned as the first man to land on the Ice Barrier and travel over its surface, and Armitage might have been named as the leader of the first party to ascend to and travel over the great polar Plateau.

Incidentally, the paging of the book reveals the fact that it was designed as one volume, for vol. 2 begins with p. 301, and as the exigencies of printing made it difficult to end vol. 1 on p. 300 four unnumbered pages had to be introduced, and so a singularly clear description of the embryology of the Emperor penguin by Prof. Cossar Ewart, which occupies those pages, has necessarily escaped the index.

As a general account of Scott's last expedition Mr. Cherry-Garrard's book surpasses all the others. Mr. Priestley's book on the northern party, Dr. Griffith Taylor's and Mr. Ponting's on the main wintering party, and Capt. Evans's account of his personal experiences are fine books, each in its way dealing admirably with special aspects but leaving the expedition as a whole unchronicled. The two great volumes of Scott's Last Journey giving the official account omit the preliminary arrangements for the expedition, of which Mr. Cherry-Garrard gives a racy account, and enter too fully into the fears and anxieties of the leader on the great southern journey to leave a clear impression on the mind. Again, the exquisite reproductions of Dr. Wilson's beautiful water-colours and the panoramic sketches of scenery give to the volumes before us a charm that in large part compensates for the very high price which their inclusion necessitates.

If poetry be indeed definable as "emotion recollected in tranquillity," Mr. Cherry-Garrard has given us a true epic of exploration. His emotion was strong and his recollection is sardonically calm. The description of the "worst journey in the world" from Cape Evans to Cape Crozier in winter darkness to obtain eggs of the Emperor penguin is the most vivid and moving we have met with in polar annals. The mellow nobility of Wilson's character and the dauntless cheeriness and resourcefulness of Bowers made them ideal companions in a desperate adventure, and despite the deprecatory references to himself we can see that Mr. Cherry-Garrard was not unworthy of his associates. To be sure, Bowers would not have worried if all the penguin eggs had been broken, nor would Wilson have taken offence at the superior aloofness (real or imaginary) of a museum official, which hurt the author severely. All the same, we think the Gilbertian humour and grotesque exaggeration of Mr. Cherry-Garrard's efforts to extort from the "Chief Custodian" an expression of the value of the objects for which three men had put their lives to the touch may well be passed by as a piece of friendly banter, for to the general reader it serves as an artistic relief to the grim horror of the quest.

The description of the main southern journey and of the ascent and descent of the Beardmore Glacier is a most valuable piece of first-hand narrative. Still more must one appreciate the story of the return of the last supporting party under Capt. Evans, which is told in large part in the very words of Lashley, one of the two "naval ratings" who saved the life of their leader by heroism as fine as ever was. The diary, given in its original lower-deck language, is a masterpiece of rugged prose that defies all rules of grammar and is incapable of imitation.

Mr. Cherry-Garrard conveys a good impression of the scientific aims of the expedition in untechnical words; but in our opinion the real value of the book is as a contribution to polar psychology. Priestley has treated of this aspect of the expedition more formally; but here we have a quarry of the raw material with which psychologists will know how to deal. As a rule, official reports fail in a candid treatment of the human element in an expedition, while the unauthorised records of subordinates usually fail in trustworthiness. Yet we know more of the mental state of Cook's companions in 1773–75 from Forster's ill-natured volumes than from the great navigator's own calm narrative, and we get delightful sidelights on Sir James Ross from M'Cormick's "Polar Voyages" in spite of the conceit and short-sightedness of the writer. We cannot view Mr. Cherry-Garrard's analyses of the character of his leader or his comrades as ill-natured, while he is certainly totally free from any suggestion of claiming superiority for himself, and, save in the case of the "Chief Custodian" referred to above, he is obviously sincere.

To future students of polar travelling this book will prove invaluable whether all the opinions put forward in it are accepted or not. We are reluctant to raise controversies that would no longer serve a practical purpose; but no future explorer can afford to pass by the criticism of the rations used for sledge-travelling or the inquiry into the real cause of the collapse of Scott's party. While the immediate cause was, as Scott stated, the shortage of paraffin for heating and the totally unexpected low temperature of the air on the Barrier surface in March, Mr. Cherry-Garrard

indicates that an unfortunate dietary had led to the slow and gradual undermining of the health of all the members, lowering their vitality to a point which made the struggle hopeless. The discussion of this subject is painful; but it is scarcely likely that the views put forward will be accepted by the survivors of this or other polar expeditions without very careful scrutiny. It must be remembered that only experience can test the sufficiency of any diet, and that the best theoretical views are open to revision in the light of new knowledge. The War included so many large-scale experiments on mal-nutrition that any one criticising Scott or his advisers for their views in 1909 must be careful to do so with respect only to the state of knowledge at that time.

Capt. Scott was a great leader, and it may be that the wave of hero-worship which rose to so unprecedented a height when the news of his fate became known overshadowed the merely human side of his character. Even if all that Mr. Cherry-Garrard says of the strength and of the weakness of his late leader stands the test of time, the question cannot but arise whether the time for such a characterisation has yet come. In the future it will be a valuable piece of comparative study to contrast one great leader with another, but it will never be fair to compare the searching analysis of Capt. Scott with the more conventional presentment of other leaders whose qualities have been dealt with, let us say, with the reticence dictated by Victorian standards of consideration for the feelings of surviving relatives.

We think that it may be possible to combine fearlessness with good taste by placing on record in some safe keeping for future study the most intimate personal criticism of explorers by those who have been most closely in contact with them; and we should like to see all personal diaries of all the expeditions secured from the risk of destruction, especially from the risk of destruction by the writers themselves in after years, by deposit with a responsible institution in trust for posterity. HUGH ROBERT MILL.

Indian Irrigation.

Triennial Review of Irrigation in India, 1918–1921. Public Works Department of the Government of India. Pp. v+222. (Calcutta: Government Printing Office.) 5 rupees.

INDIA is a land of many problems, and not the least difficult and perplexing is that of irrigation. The meteorological conditions vary there more than anywhere else in the world, within an equivalent area. The country contains alike the locality (Cherrapunji) with the greatest recorded average annual rainfall (460 inches) and arid tracts where rain is practically unknown. More troublesome than these extremes is the general irregularity of the incidence of precipitation, its unequal distribution, its capricious periodicity, its liability to entire failure. Drought and famine are ugly visitants to a country, but they are only too familiar to the unfortunate inhabitants of the land of the Moguls.

There is no need, therefore, to enter any plea or make any justification for irrigation works in India. Not merely the happiness and comfort but the very existence of many thousands of lives depends upon the provision of supplies of water by artificial means to the crops during the dry season.

The volume before us contains a record of the irrigation works carried out during the triennium 1918–21 by the Public Works Department of the Government of India. It also embodies an extremely interesting review of the inception and progress of various undertakings of the kind during a period of some forty years. The 10½ million acres irrigated by Government Works in 1878–79 have grown to 28 million acres in 1919–20. Perhaps a better method of forming an idea of the works themselves is to speak in terms of channels constructed. By the year 1900–1 there were 39,142 miles of Government channel in operation. In 1920–21 this length had increased to 55,202 miles. Every year there has been an average addition of 800 miles.

From an agricultural point of view, the triennium 1918–21 consisted of a central prosperous year between two lean years. In the first year the average deficiency in the rainfall throughout the plains was greater than in any preceding year since 1877. In 1919, on the other hand, the precipitation for the whole season was 5 per cent. above the normal. In the following year another set-back occurred, and the percentage below the normal ranged from 13 in the United Provinces to no less than 83 in Sind. Commenting on these facts and their relationship to the irrigation works already in existence, the report truly says: "But for the works, on millions of acres the crops would never have come to maturity; on millions more, no crops at all could have been sown. . . . It is safe to say that even 20 years ago, many tracts would have suffered from widespread famine which, owing to the facilities now afforded for irrigation, passed through the triennium unscathed."

The review of the triennium period includes a notice of the great Triple Canals project in the Punjab, commenced in 1905 and finally completed in 1917. It consists of 433 miles of main canals and branches and 3010 miles of distributaries, in connexion with which nearly 20,000 miles of watercourses have also been constructed. The total area commanded is 6250 square miles, and it is proposed that 1,675,000 acres shall be irrigated annually. Another notable undertaking referred to is the Divi Island project in the delta

of the Kistna river in Madras, which is an attempt to effect irrigation on a large scale by pumping. The installation comprises eight double-cylinder Diesel engines, each of 160 h.p. and driving a centrifugal pump capable of discharging 73 cu. ft. per second on a 12-foot lift. Another engine is to be added shortly.

Among the works now in hand is the Sarda Canal in the United Provinces. The decision to construct this canal finally settles what has probably been the most contentious question in the irrigation of India. The controversy over the matter has lasted for more than half a century. The canal when constructed will irrigate the North-Western districts of Oudh. It will comprise 478 miles of main canals and branches and 3370 miles of distributaries.

Space does not admit of reference to other interesting schemes which are described in the report. Its 222 pages are replete with useful information, which will repay study by those interested in the subject. There is a helpful series of maps and diagrams, many excellent photographs, and some tabular statements showing the financial results of the various irrigation operations throughout India. BRYSSON CUNNINGHAM.

Scientific Societies in the British Isles.

The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland: a Record of the Work done in Science, Literature, and Art during the Session 1921–22 by numerous Societies and Government Institutions. Compiled from Official Sources. Thirty-ninth Annual Issue. Pp. vii+374. (London: C. Griffin and Co., Ltd., 1922.) 15*s.* net.

THE appearance once more of Messrs. Charles Griffin's well-known Year-Book affords us an excellent opportunity for taking stock of the position of science in the British Isles. The volume is arranged in the customary style, the various bodies dealt with being divided among fourteen sections according to the nature of their activities. In each section again, there is a further grouping according to the location of the society, institution, or department in London, the Provinces, Scotland, or Ireland. As is only to be expected, most of the more important entries appear in the London groups. In each case, some particulars of the society or institution are given, together with a list of its publications during the year when available.

The total number of societies, research departments, etc., appearing in the 1922 Year-Book exceeds 550, of which it is fair to say that some 480 are concerned, directly or indirectly, with science. The remaining 70 are accounted for by literature, history, and law. In addition to these, there are long lists of local societies and clubs interested in photography, law, or medicine. The distribution of the societies among the various sections is also interesting. Section 1, including bodies dealing with all branches of science, has 75 entries; sections 5 and 7, covering biology and mechanical science respectively, have 90 each; section 13, on archæology, has 63, while section 14, on medicine, has 54 entries apart from the long list of local medical societies.

The various societies and bodies of a similar nature appearing in the Year-Book can be divided fairly sharply into two distinct groups; those which exist for the publication of research, and those which are better described as functioning for the popularisation and spread of knowledge. Of the five hundred or so entries appearing, about one hundred seem to fall into the former group; and of these 14, including the Geological Surveys, the National Physical Laboratory and the Royal Observatory at Greenwich, are supported by Government.

A mass of similarly interesting information exists in this valuable publication, and it may seem ungracious to ask for more. That is, however, the penalty of providing good fare. The sub-title of the volume states that it deals with the year 1921–22, but, for example, it is somewhat late in the day to find information on the British Association brought up only to the Edinburgh meeting of 1921. Further, we would suggest the inclusion of the numerous Research Associations now in existence, while it would add much to the interest of the volume if the number of members of each society could be indicated. A few errors in classifying the entries have been noticed; for example, the Nature-Study Society and the School Nature-Study Union appear in the section headed Psychology. These are, however, minor blemishes in a most valuable publication, which we believe is the only single volume providing an outline survey of the activities of most, if not all, the learned societies of the British Isles.

Aluminium and its Alloys.

(1) *Aluminium and its Alloys.* By Lieut.-Col. C. Grard. Translated by C. M. Phillips and H. W. L. Phillips. Pp. xxxiii+184+16 plates. (London: Constable and Co., 1921.) 17*s.* 6*d.* net.

(2) *The Institution of Mechanical Engineers: Eleventh Report to the Alloys Research Committee: on Some Alloys of Aluminium (Light Alloys).* By Dr. W. Rosenhain, S. L. Archbutt, and Dr. D. Hanson. Pp. ii+256+24 plates. (London: Institution of Mechanical Engineers, 1921.) 42*s.*

(1) LIEUT.-COL. GRARD'S book is essentially a treatise on the mechanical properties of aluminium and some of its commercial alloys. The extraction of the metal is described in two pages, and no more detail is given than in an elementary textbook,

although there are several plates showing the power houses of Continental works. The account of the economic position of the industry is also too meagre to be of much use. The valuable part of the book consists of a long series of diagrams of mechanical properties of metal that has been subjected to various thermal and mechanical treatments, and of a corresponding series for certain of the light alloys and for the aluminium bronzes. Tensile strengths are given in metric and British units—an excellent practice.

The lack of any theoretical discussion deprives these sections of much of their value. The ageing of duralumin and similar alloys is a puzzling phenomenon when presented in the form of a mere record of tensile and hardness tests, but becomes comprehensible when considered in the light of microscopical and electrical evidence, and interpreted by means of the theory of solid solutions. Most of the photomicrographs represent the copper-aluminium alloys, commonly called aluminium bronzes. The writer appears to be unaware of the work that has been done in this country, at the National Physical Laboratory and at the Royal School of Mines, which has thrown so much light on the properties of this metal and of the light alloys. The book will be found useful chiefly for reference, when information is sought as to the strength, hardness, cupping quality, etc., of the alloys with which it deals.

(2) The latest report of the Alloys Research Committee is of a very different standard. The recent work carried out at the National Physical Laboratory has led to the preparation of several new alloys of technical importance, the most remarkable being the alloy "Y," which retains its strength and resistance to alternating stresses at elevated temperatures, and is also resistant to corrosion. This alloy contains copper, nickel, and magnesium. The report includes studies of the constitutional diagrams of several of the binary and ternary systems, and an investigation of the causes of age-hardening in aluminium alloys. In this connexion the importance of magnesium silicide as a hardening agent is shown, and the changes of hardness with time and temperature are correlated with the changes in solubility of this compound in the solid solution. The principal casting alloys are found, from measurements extending over long periods, to be stable in dimensions, and there is no doubt that these researches have added to the range of structural materials of high quality available to the engineer, and that a great future lies before light alloys, suitably heat-treated. The photo-micrographs illustrating the volume are remarkably clear, and their beauty will be appreciated by all who have had occasion to prepare these alloys for examination. C. H. D.

Our Bookshelf.

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Prof. Dr. E. Abderhalden. Abt. V: Methoden zum Studium der Funktionen der einzelnen Organe des tierischen Organismus. Teil 3A, Heft 3, Lieferung 69: Entwicklungsmechanik. Pp. 441–538. 630 marks. Abt. IX: Methoden zur Erforschung der Leistung des tierischen Organismus. Teil 1, Heft 2, Lieferung 71: Allgemeine Methoden. Zoologische allgemeine Methoden. Pp. 97–438. 2160 marks. (Berlin und Wien: Urban und Schwarzenberg, 1922.)

THE number of subjects included in these two parts of Abderhalden's great "Handbuch" precludes, in a short notice such as the present, anything beyond a mention of the chief topics discussed.

Lieferung 69 is devoted to "Entwicklungsmechanik." Here Herbst discusses methods of artificial parthenogenesis; Günther Hertwig, the method of irradiation of the germ-cells by radium and Röntgen rays; Romeis, the technique of investigations on the action of organic extracts, such as muscle, thyroid, and suprarenal extracts, on invertebrates, anuran tadpoles and urodele larvæ; and Braus, the methods of tissue cultures *in vitro*.

Lieferung 71 is more extensive. Przibram is responsible for a chapter of about 90 pages on "Living Material for Biological Investigations." In this he considers the choice of species to be employed in biochemical researches, how and whence to obtain them, their transport and maintenance, the terrarium, the aquarium (including the setting up and aeration of sea-water aquaria), and the insectarium. In addition, there is given some account of the application of chemical agencies, the means of obtaining and maintaining various degrees of moisture and of pressure, the application of mechanical agencies, and the alteration of the action of gravity. The subjection of the animals to the action of electricity and of magnetism, the application of heat and of light (measurement of the degrees of light, coloured light, ultra-red and ultra-violet rays), and the isolation and marking of the subjects of the experiments are also dealt with.

Two sections of 40 pages each are devoted to methods of preservation of zoological preparations and to zootomical technique. The methods of reconstruction by means of wax or paper plates are fully explained, while shorter but useful sections deal with the preparation of simple text-figures by the author, and with the production of transparent museum preparations.

Oxidations and Reductions in the Animal Body. By Dr. H. D. Dakin. Second edition. (Monographs on Biochemistry.) Pp. ix+176. (London: Longmans, Green and Co., 1922.) 6s. net.

THE complex chemical compounds taken as food by animals are not brought by a single reaction of oxidation to their final states of water, carbon dioxide, and urea. They pass through many intermediate stages, which are of great interest and importance, not only from the purely chemical aspect, but also on account of the fact that many of them play a part in the production

of substances which have a profound influence on physiological processes. It is the object of Dr. Dakin's monograph to describe these intermediate stages, and the reader may be satisfied that he will obtain the latest information on the subject. The book is to be highly recommended. It has a good index and a complete bibliography. The section on carbohydrates has been almost entirely rewritten since the previous edition. The description of oxidations which can proceed with the aid of water without free oxygen is of interest in itself, but such processes are of subsidiary importance in the higher animals, since these cannot exist without free oxygen.

With reference to certain views held as to the significance of catalase, the author concludes that there is no evidence that this enzyme has any connexion with oxidation; it may, however, be of use in decomposing excess of hydrogen peroxide, produced in the course of autoxidation, into inactive oxygen. The author points out that he is not concerned with the thermodynamics of the various reactions, nor with the catalytic mechanisms by which they are brought about, although he devotes a few pages to autoxidation and the peroxide systems, and to the important glutathione system of Hopkins. This omission is not to be regarded as a serious defect, because the object of the monograph is of a different kind. It reminds us, however, that there is an urgent need for a monograph dealing with the thermodynamics and general physical chemistry of the oxidation mechanisms of the living organism. W. M. B.

A Treatise on the Integral Calculus: with Applications, Examples, and Problems. By J. Edwards. Vol. 2. Pp. xv+980. (London: Macmillan and Co. Ltd., 1922.) 50*s.* net.

IN the second volume of his large treatise on the integral calculus, Mr. Edwards deals with multiple integrals, gamma functions, Dirichlet integrals, definite integrals in general, contour integration, elliptic functions, the calculus of variations, Fourier series and integrals, mean values and probability, and the harmonic analysis. The volume contains an immense collection of formulæ and questions extracted from examination papers and from the older literature of the subject, which may prove useful for reference to the sophisticated reader, but are more likely to repel than to inspire the students for whom the book appears to be intended.

Mr. Edwards is confessedly out of sympathy with modern tendencies in mathematical education, and thinks that students do not learn enough skill in manipulation. He prefers that they should devote their energies to acquiring proficiency in methods which are in many cases obsolete, rather than that they should obtain the same results by a systematic application of a few powerful general theorems. This tendency is particularly obvious in the chapters on definite integrals and on elliptic functions. In consequence, that residuum of problems for which the older methods are still the most suitable receives rather less than justice. His use of the methods of differentiation and integration under the integral sign, change of the order of integration, etc., is uncritical, and is not likely to conduce to clear thinking on these important subjects. His definition of a function of a complex variable is unsatisfactory, and entirely misses the point in failing to emphasise the crucial importance of the existence of a unique derivative. In the bibliography of the chapters on the calculus of variations he refers the reader to a number of obsolete treatises, but ignores the important modern works of Hadamard and Kneser.

The teacher of to-day may use this work for reference himself, but he will scarcely wish his pupils to make their first acquaintance with the processes of analysis from its pages. E. G. C. POOLE.

Farm Buildings. By W. A. Foster and Deane G. Carter. (Agricultural Engineering Series.) Pp. xv+377. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 15*s.* net.

THE little work under notice is intended to guide the American farmer and agricultural student in designing and constructing farm buildings. It is stated that farm buildings have had their most rapid development in America in the years since 1910. Prior to that one could, and indeed still can, find the early buildings put up by the first settlers, made of logs, if trees were abundant, or of sods or boards if they were not, as happened on the prairies. Now, however, these rough constructions have largely disappeared, or remain only as stores of subsidiary importance, and their place is taken by large new and characteristic-looking structures of steel and concrete. The change is not only one of convenience: it represents a great saving on the farm. It is estimated that at least 100,000,000 dollars is lost annually to American farmers through depreciation of farm machinery due to lack of proper housing; that 200,000,000 dollars are lost annually owing to the consumption of badly stored food by rats; and further, that considerable increases in milk and meat production could be obtained if the animals were better housed.

The authors discuss the best types of barns, stables, cowsheds, pigstyes, etc., and give many illustrations showing how to adapt the design to the available situation or space, and what materials should be used in construction.

The English agricultural student will find the volume of particular interest for its sections on silos, pigstyes, and cattle-sheds, and for a fund of information showing how the American farmer, suffering from even greater shortage of labour than his British confrère, has nevertheless succeeded in putting up buildings of undoubted utility.

British North Borneo: An Account of its History, Resources and Native Tribes. By Owen Rutter. Pp. xvi+404+plates. (London, Bombay, and Sydney: Constable and Co., Ltd., 1922.) 21*s.* net.

ALTHOUGH Sir West Ridgeway, the chairman of the British North Borneo Company, contributes a preface to this volume, it is in no sense an official publication. This will be appreciated by those who are conversant with recent criticisms of the company's methods of administration. The author is both fair and unbiassed.

The story of North Borneo is not without stirring incident. In the last century its coast was infested with pirates, whose extermination was first undertaken seriously in 1845 at the instigation of Rajah Brooke of Sarawak. Their subjugation was completed only in 1879, the year the British North Borneo Company was

formed. Of the numerous native risings with which the company has had to deal, the most formidable was that headed by the redoubtable Mat Saleh, who was defeated and killed in 1899.

Mr. Rutter gives a very complete account of the geography and economic resources of the country, of which, however, the greater part is still undeveloped. The native population offers many points of interest to the ethnologist. The Dusuns and Muruts, the up-country agricultural population, are of Indonesian stock. The coastal peoples, Bajau, Illanun, and others, represent an incursion of Malayan stock. The latter are Mahommedans, while the former are pagan. A remarkable feature in the religious beliefs of some of the Dusuns is the cult of the sacred jar, in each of which a small company of relatives has a joint ownership.

Incandescent Lighting. By S. I. Levy. (Pitman's Common Commodities and Industries.) Pp. x+129. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 3*s.* net.

THE author has produced an interesting and well-written book which gives a good historical account of the development of artificial lighting; particular attention being given to incandescent lighting. A chapter is devoted to the growth of the rare earth industry. The dramatic discovery of rich deposits of monazite in the British Empire, and notably at Travancore in India during the War, was a great help to this country; the sands at Travancore contain more than 45 per cent. of monazite. The processes of extracting pure thorium compounds from monazite demand great ingenuity, and they are well described. Descriptions are also given of the recent great improvements in the manufacture of incandescent mantles. The author gives a very fair comparison of the costs of oil, gas, and electric methods of lighting. The average candle-power (formerly called the mean spherical candle-power) should, however, have been taken as the basis of the comparison and not the mean horizontal candle-power.

Lubrication and Lubricants: a Concise Treatment on the Theory and Practice of Lubrication; the Physical, Chemical, and Mechanical Properties and Testing of Liquid and Solid Lubricants; with Notes on Recent Developments and Examples from Practice; for Engineers, Chemists, and Students. By J. H. Hyde. (Pitman's Technical Primers.) Pp. x+114. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 2*s.* 6*d.* net.

ALTHOUGH very uneven, the little book under notice is interesting. The definitions are usually rather carelessly given, if at all. Thus, in the chemical section (which is not very satisfactory) neither the iodine nor the acetyl value is explained, although both are quoted. Langmuir's name is incorrectly spelt throughout the book. The chapter on recent developments is of interest, and deals among other matters with the variation of efficiency with temperature and the effect of adding vegetable to mineral oils. We have previously commented on the very ambitious titles of the small books in this series; the remark applies in the present volume, and any one who expects what he might from the title will be disappointed.

Molybdenum Ores. By Dr. R. H. Rastall. (Imperial Institute: Monographs on Mineral Resources with Special Reference to the British Empire.) Pp. ix+86. (London: J. Murray, 1922.) 5*s.* net.

THE molybdenum minerals, their origin and mining, are dealt with, and an account of the metallurgy of molybdenum is also included in this work. The account of the electrical treatment on p. 5 does not seem complete, as no mention is made of the furnace charge. The sections on the sources of supply appear to be exhaustive, nearly every reported occurrence of molybdenum being mentioned, together with the production, if any. The table on p. 12 indicates that the demands for the metal are limited; the production in 1918 was equivalent to about 800 metric tons of metal; that in 1921 was only 7 tons. The principal use is in the preparation of special steels; a lower amount of molybdenum will replace tungsten in a high-speed tool steel, and a small amount of molybdenum is said to improve a mild structural steel.

History of Chemistry. By Dr. F. P. Venable. Pp. vii+169. (London and Sydney: D. C. Heath and Co., 1922.) 5*s.* net.

DR. VENABLE'S "History of Chemistry" is a second edition of a book that appeared in 1894. A history of chemistry which contains no illustrations or diagrams, and in which formulæ are used only in the few passages where their historical development is under consideration, must be subject to serious limitations and in the nature of things cannot be much more than a sketch. It is not quite clear to the reviewer what type of reader will be attracted by such a sketch; but it is likely that the well-read student of chemistry will find some interest in this brief outline, and may be led by it to follow up the history of his science in some volume in which more details are given.

The Elements of Scientific Psychology. By Prof. Knight Dunlap. Pp. 368. (London: Henry Kimpton, 1922.) 18*s.* net.

THE author has here produced one of the best and most useful of the many text-books now available on psychology. He is a good experimentalist, and is thoroughly alive to the importance of a knowledge of physiology to the psychological student. He shows himself able at the same time to maintain a distinctively psychological point of view. The main faults of the book are that it attempts to cover too much ground, and that occasionally it presents, as text-book material, conclusions which require to be subjected to much further research.

Grundzüge einer Physioklimatologie der Festländer. Von Dr. Wilh. R. Eckardt. Pp. v+123. (Berlin: Gebrüder Borntraeger, 1922.) 4*s.* 6*d.*

DR. ECKARDT has produced a useful little book, which aims at giving an outline, according to the most recent investigations, of the distribution of temperature, pressure, and precipitation in the main land-masses. Particular attention is paid to Europe. There are a number of sketch maps and diagrams, and a short bibliography. The book gives in a convenient and authoritative way information that is not generally accessible in a collected form. It should prove very acceptable to students of geography.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Wegener Hypothesis of Continental Drift.

THE chief value of the discussion on the Wegener hypothesis is that it has given rise to a reconsideration of the problems presented by the configuration and relations of the major features of the earth's surface.

The elaborate structure of theory built up by Dr. Wegener, and so effectively criticised by Mr. Lake (see NATURE, February 17, p. 226), will have few, if any, thorough-going defenders in this country, but some of its leading features cannot be lightly dismissed. Mr. Crook (NATURE, February 24, p. 255) has recalled to our notice the suggestions put forward by Osmond Fisher, and later by W. R. Pickering, that the separation of the moon from the earth, which Sir George Darwin believed to have resulted from tidal action, took place in the region now occupied by the Pacific; that our satellite took with it three quarters of the earth's crust, and that the remaining quarter, from which our continents trace their descent, has since split up into fragments which have drifted apart over the heavier fluid magma below, leaving channels between them, the most important of which is now the Atlantic Ocean. Here we have an interesting approximation to certain of the assumptions of the Wegener hypothesis; but both Osmond Fisher and Pickering, it will be noticed, considered the separation of the continents to be the result of a general drift towards the Pacific. In this they differ from Wegener, who attributes it to a varying lag of the earth's crust relatively to its interior, so that one portion became separated from another.

If the former view is well founded there should be a certain amount of symmetry about an equatorial diameter drawn to the centre of the Pacific from its antipodes in Africa. It is therefore interesting to note that Prof. Sollas in a communication to the Geological Society in 1903 (Q.J.G.S., vol. 59, pp. 184-8) declares that "an axis of terrestrial symmetry" "passes through the middle of Africa on the one side, and the Pacific Ocean on the other," a depression in the Pacific corresponding to a dome in Africa. He is inclined to accept Osmond Fisher's hypothesis, that the Pacific owes its origin to the birth of the moon, and suggests that the African dome represented an unsuccessful attempt on the opposite side of the world to give birth to a second satellite. This symmetry is, it is true, obscured by the east and west folding, which is such a frequent feature in the earth's crust, and is attributed by Wegener to a drift away from the poles towards the equator, but is not improbably the result of a movement from the equatorial region to the poles due to the slowing down of the earth's rotation and consequent decrease of the ellipticity of its figure and of the equatorial protuberance.

Like Mr. Crook, Prof. Sollas follows Suess in believing that the Atlantic owes its origin not to continental movement but to the foundering of the tract which it now occupies. My principal object in writing is to point out that the hypothesis of the drifting apart of North and South America from Europe and Africa is quite consistent with that of a subsidence and submergence of a great part of the ocean area that now separates them; and that the latter is in fact the consequence of the former.

The evidence, based on similarity of lithological characters and fossil contents of the rocks, that South America east of the Andes and the Falkland Islands were once in much closer proximity to Africa, is to my mind conclusive, and scarcely less is that of a former association of a great part of India and of Australia with Africa. There seems, too, every reason to believe that, although masked in places by other tendencies, there has been a general movement of the lighter continental crust or Sial from Africa towards the Pacific. This appears to be a drift from a region of a comparatively low gravity to one of higher gravity.

As we have seen, Wegener and others believe that the earth's crust lags behind the solid core as a result of tidal retardation, and that this lag varies from point to point. If this is the case, the folded mountains that have their roots deep in the earth's interior will, no doubt, have a smaller lag than other portions of the earth's crust, and therefore, as Prof. Joly suggests, a relative movement from west to east. How far such movements are of importance it is at present impossible to say.

Whatever may be the ultimate causes of the relative movement of continents, they can only be effective when they operate in a direction in which the earth's crust does not possess sufficient rigidity to oppose them. We can no longer suppose that there is a fluid substratum to the earth's crust. It is probable that the solid crystallised zone below the oceans is usually fifteen to twenty miles in thickness, and at those depths the enormous pressure of 90 to 120 tons to the inch will give a comparatively high rigidity at the temperature of about 800° C. that may there prevail, even to an uncrystallised magma. Where, however, a great thickness of sediment has accumulated in the neighbourhood of a continent on a sea-bottom, it will—as Dana was the first to point out—by acting as a blanket, cause the temperature of the rocks beneath to rise and become less rigid, especially if they are basic in composition. In this rise of temperature, Prof. Joly believes radioactivity plays an important part. At the same time the area concerned will sink slowly to satisfy the requirements of isostasy, forming a trough parallel to the coast line. If a period of compression in a direction at right angles to the coast supervenes, the rocks will yield to it and the trough will be laterally compressed and deepened while the sedimentary accumulations are thrown into folds. In this way the land masses surrounding the Pacific have been enabled gradually to advance inwards from its circumference, their progress being marked by folded mountain ranges. Yet the Pacific, as a whole, apart from the marginal portions, being comparatively free from sedimentation, has preserved its rigidity and successfully resisted compression.

On the other hand, there seems reason to believe that Africa is in the main the centre of a region of tension, due to the outward drift of continental masses in the circumstances already described. It is obvious that the separation caused by such a movement must involve a deficiency of material in the separating tract, and a loss of stability on the margin of the separated masses. Sometimes the blocks into which they are divided by jointing will fall forward one upon another like a succession of bricks and so give rise to a number of faults dipping away from the rift. Examples of this are seen in Skye and Caithness. More usually the slow subcrustal movement towards the line of fracture will carry the solid crust with it. The result will be a series of faults hading towards the region of tension and with a downthrow in that direction. In North Devon and Cornwall I have shown that there is evidence that there has been a general debacle of the rocks towards the west in Tertiary times. North-west and south-east faults occu every few yards with a considerable hade to the south-

west; but the slickensides show that the movement was oblique, partly down the fault planes and partly parallel to the strike of the faults to the north-west, the latter component being the more important, so that the total movement to the west must have been considerable. At the same time there has been a general tilt of the country in that direction. I am given to understand that somewhat similar faulting occurs in the South of Ireland, and, no doubt, it exists elsewhere on the eastern shores of the Atlantic. The total westward movement visible on the land does not amount to more than a few miles, but the downward displacement that accompanied it must have resulted in the submergence of a large area to the west, and the same structures, no doubt, extend still farther in that direction under the sea. In the actual neighbourhood of the rift (to use the convenient term employed by Prof. J. W. Gregory) there may well be a complete absence of the Sial, so that the Sima would be found close below the abysmal deposits of the deep sea, as Wegener supposed to be the case. There is, however, no reason to suppose that the opposite shores of the continents represent the actual margins of the rift, and we cannot expect to find the close correspondence between them which he endeavours unsuccessfully to demonstrate. Submarine plateaus rising in the midst of greater depths may represent portions of Sial submerged between two rifts.

The solution of these problems should be regarded as an urgent task for the immediate future. There is little doubt that further information with regard to the density of rocks below the sea-bottom would result from the systematic measurement of the variation of gravity at sea with concurrent determination of its depth. The new methods that are now available are at once more rapid and more trustworthy than those previously employed, and might well be carried out either by the Navy or the great ocean liners. Valuable information, too, will be yielded by the Eötvös balance with respect to the rocks below the sea in the immediate neighbourhood of the shore.

JOHN W. EVANS.

The Function of Mendelian Genes.

IN NATURE of March 3 there appears a letter from Mr. Julian Huxley on "The Function of Mendelian Genes," in which he criticises a paragraph in a review of mine published in NATURE of January 20. As I think that the difference between Mr. Huxley and myself is due to a certain extent to a misunderstanding of my meaning, perhaps you will allow me space to make a brief reply.

Mr. Huxley's main point is that in treating Mendelian genes as measures of pathological damage to the hereditary substance, I forgot that each discovery of a presumably pathological mutant gene implied the existence of an allelomorphic normal gene in the type, and that in this way we were enabled to analyse the hereditary machinery of the type.

The paragraph to which Mr. Huxley alludes was a small item in a review devoted to vitalism. Mr. Huxley and I had a prolonged battle in *Science Progress* last year, and perhaps before long we may have another friendly encounter in the same journal. As he alludes to this contest in a footnote, I may here say that he is incorrect in stating that he forced me to admit that not all mutations were pathological. All I said was that I could not make such a universal statement without examining each case, but I may add that I have yet to meet with the Mendelian mutation which is not pathological. My answer to Mr. Huxley is that of course I recognise the existence of hypothetical allelomorphic normal genes, which taken together make up the hereditary machinery of the type, but I doubt the value of the analysis of this machinery into genes at all. The only analysis of the hereditary complex which seems to me to be at all interesting or fruitful, is its dissociation into the factors out of which it was actually historically built up. I regard this complex as the solidification, so to speak, of the reactions of the race to the varying experiences through which they have gone during past ages. New habits have been superposed on old ones, with accompanying modifications of structure; and when we have unravelled this history completely, we have given as exhaustive an account of the origin of the hereditary machinery as is possible.

The normal "gene" is an imaginary section of this machinery invented to account for the damage which a mutant gene introduces. Mr. Huxley alludes to the existence of multiple allelomorphs as *proving* that the recessive mutant gene is not the mere absence of something which we call the dominant gene. I think that a series of multiple allelomorphs inevitably suggests a graded series of varying degrees of damage, or, as we may phrase it, a series of increasing intensities of defect. Such a series is given by the mutants of the red eye of the wild Drosophila. These are listed as vermilion, scarlet, cherry, pink, eosin, cream, and white! What other plausible explanation can be given of these than the gradual disappearance of the dark red pigment of the normal eye?

One of the mutant genes of Drosophila produces a variation termed "balloon wing." In insects showing this variation the two layers of ectoderm forming the wing are widely divaricated from each other, the space between them being occupied by a bubble of air. Now there is a general consensus of opinion based on palæontology, embryology, and comparative anatomy as to the evolutionary history of insects' wings. They began as slight lateral extensions of the dorsal terga of the thorax, at first in all three segments; but later they were confined to the posterior two segments. In the beginning they served merely as parachute planes to break the fall of the insect when it leaped into the air; later, as they grew longer and flexible, they became capable of independent movement, and so developed into the varied types of wing found at the present day. On what phase, one may ask, of this history of progressive functional evolution does the existence of the balloon wing mutant throw the smallest light?

We are gradually learning to recognise that the body of an animal is built up by the co-operation of the semi-independent growths of a number of tissues and organs which, however, mutually limit and determine the extent of each other's growth. The compromise which is arrived at, is expressed in the normal specific or racial structure of the animal, and may be expressed by the term "regulatory balance." When the race is exposed to new surroundings, the regulatory balance is altered and a new race is evolved. This accounts for the fact noticed by Sturtevant that allied species differ from one another in numbers of minute points affecting all the organs of the body, whereas mutations are characterised by marked differences affecting only one or two organs. Mutations may be defined as pathological disturbances of this regulatory balance; if they are so severe as to produce a noticeable effect on the offspring when introduced by only one parent, they are dominant; if their effects are only apparent when both parents are affected, they are recessive.

Mr. Huxley's comparison of the mutant black mouse to the melanic local races of wild species is unfortunate. The black mouse (which I have often reared) is covered with a fur of so uniform colour as to make it exceptional among mammals. It may be

compared to the various melanic sports which occur in other species of mammal, such as the black leopard. I have seen a black individual among a litter of the common Canadian squirrel.

On the other hand, a melanic local race implies a new regulatory balance. As an example of the relation of racial character to the environment, I may mention the common red grouse of Scotland, supposed to be the only species of bird peculiar to Britain. In Europe there is the allied species of willow grouse, differing in having the tips of the primaries white and in turning white in winter. When a Scotch landowner imported the willow grouse he found that in two or three generations they became indistinguishable from the red grouse; and when red grouse were introduced into Norway, they reverted in a few generations to a form indistinguishable from the willow grouse. E. W. MACBRIDE.

Definitions and Laws of Motion in the "Principia."

IN his recent interesting article (NATURE, February 17) on the Definitions and Laws of Motion in the "Principia," Sir George Greenhill reopens a very old discussion (NATURE, vol. 39, 1888-9). It might have been expected that the lapse of one-third of a century would have been sufficient for reconciliation of the engineer and the physicist. Every scientifically trained engineer knows, as Sir George Greenhill knows, that no confusion is introduced by the employment of a given multiplier or divisor in every term of an equation.

The only new feature now given in the mathematical discussion lies in his equation (1),

$$Wv/g = Ft,$$

in which it is insisted that the g as a divisor *must* be attached to the v and not to the W. But, in the weight problem, this merely makes the equation an identity with $W = F$; and, if we introduce F as a non-gravitational force, say by the use of a spring-balance, or a column of compressed air, etc., still giving t its old value, we find a different average F, and therefore a different W, at different localities. It is this local variation of W which reveals to the physicist an absence of that aspect of invariance, the existence of which he, as a scientific man, feels compelled to search for. And his search is not in vain; for he finds that, with v, t, and average or actual F (non-gravitational) all constant, W *is* proportional to g, and therefore the attachment of g to W is justified, in his belief, by Nature. In fact, he has come into contact with the *materiae vis insita*.

I have never known any student of engineering who, having first had a normal training in physics, felt compelled, in his engineering studies, to alter his ideas. He knows that his "factor of safety" in constructional details is large enough to cover such variations of g as he meets with in practice. The real quarrel (if it still exists) is only one regarding the use of the word "pound," and the context in the engineer's or the physicist's statement usually prevents confusion, even if it were not the case, as I have always found it to be, that the student of engineering is quite willing to speak, when clearness requires it, of the mass of a pound and the weight of a pound.

I do not agree with Sir George Greenhill that Mach was right in saying that Newton's Def. I. is only a definition of density. I regard it as presuming that the meaning of density is known, so that the definition is really one of the *quantitas materiae*, to which the *materiae vis insita* or *inertia massae* is proportional. It then implies the physical law that inertia is independent of the form of aggregation, and depends, for a specific material, only on the extent of the aggregation. Nor do I agree with him that Newton's use of many different words for the name of the same thing was undesirable. We must remember that Newton was the pioneer, introducing new ideas, and requiring therefore to use every form of phraseology or nomenclature that might help to make them understandable.

Sir George Greenhill disagrees with Tait, and credits him with the honour of introducing innovations. Now Tait was a modest man, and a loyalist towards Newton. He gives the honour to Newton, whose interpreter only he was. The further statements on this point made in Sir George Greenhill's second article do not alter the position.

Tait's wise words (*l.c.*) of a third of a century ago are well worth attending to to-day, apart from electrons. He said ". . . mass is the personal property of a body, one of the invariable things in nature:—and not an accidental property dependent, for its amount and even its very existence, on the momentary surroundings. The letter M has hitherto been used by Newtonians in this sense. If anyone has since attached to it another and different sense, *he* is responsible for the consequent confusion. Would it not be well if Prof. Greenhill, and the School to which he has attached himself, would kindly leave to Newtonians their M, as defined for them by their Master; and (with severely logical consistency) turn it upside down (thus, W) when they wish to embody their own revolutionary definition? No Newtonian will refuse to recognise $Wv^2/2g$ as a correct expression for so much energy:—though he will probably think it both clumsy and complex, and will prefer to write as usual his $Mv^2/2$." W. PEDDIE.

University College, Dundee.

IN his article under the above title in NATURE of February 17, Sir George Greenhill expresses the opinion that it would be worth while to examine the previous state of the theory of dynamics to see what laws were current before the statement as given by Newton. The evidence of Newton on this point is often overlooked, though it is noted by Tait. In the scholium to Corollary VI. on the Third Law of Motion, Newton freely acknowledges the work of his predecessors.

"Hactenus principia tradidi a mathematicis recepta et experientia multiplici confirmata. Per leges duas primas et corollaria duo prima Galilaeus invenit descensum gravium esse in duplicata ratione temporis et motum projectilium fieri in parabola; conspirante experientia, nisi quatenus motus illi per aeris resistentiam aliquantulum retardantur."

In these days of the Fletcher trolley and Atwood's machine it would be interesting to know what were the experiments Newton had in mind as confirming dynamical principles. Mach has pointed out the great achievement of Galileo in arriving at the First Law of Motion, but he does not assign him credit for a knowledge of the Second Law. It is quite apparent from the above quotation that in the time of Newton there existed a tradition that Galileo's teaching of dynamics embodied the Second Law as enunciated in the "Principia." This is borne out by Lagrange in his introduction to the second part of his "Mécanique Analytique," in which he states that the Second Law is contained in the note added by Viviani at the suggestion of Galileo to the "Dialogues of Two New Sciences" (Eng. Trans. Crew and De Salvio, p. 184), deducing that the speeds falling down planes of different inclinations but of the same height are equal. In this note it is assumed as self-evident that the

accelerations of a given body are as the forces producing them. This result combined with the fact that all bodies have the same gravitational acceleration corresponds to the form ($F/w=a/g$) recommended for elementary teaching and favoured by Sir George Greenhill.

The acknowledgment which Newton makes to Wren, Wallis, and Huygens for the discovery of the laws of impact is generally known in connexion with his description of his own experiments on impact. His attitude towards these experiments is different from that of the critical exposition of dynamics of to-day, in which the Third Law is placed in the position of honour from which the Second Law is derived by observation or experiment. With Newton, however, the Third Law requires justification, as shown by the conclusion of his description of his experiments on impact, "atque ideo actionem et reactionem esse aequales."

One other extract is worthy of attention. Under Definition III. of *materiae vis insita* Newton remarks, "Per inertiam materiae fit ut corpus omne de statu suo vel quiescendi vel movendi difficulter deturbetur." This objective view of inertia is better adapted for the general qualitative introduction to inertial mass than the innate view consequent on an initial statement of the First Law. This objective view frequently finds expression in elementary text-books, but might receive greater emphasis in view of the electromagnetic theory of inertia, and the initial discrimination between inertial mass and gravitational mass forced on us by the modern theory of relativity. The quantitative definition of mass as a measure of inertia merely interprets "difficulter deturbetur" in terms of acceleration. We may say then, as a preliminary to a more exact definition, mass is a measure of the difficulty of accelerating a body.

The Resonance Theory of Hearing.

I HAVE been reading with great interest various accounts of ingenious models made to illustrate the resonance theory of hearing, but I have been unfortunate enough to miss any clear reference to any structure in the cochlea which could respond on a physical basis to all vibrations which are capable of being appreciated by the human ear, or rather nervous system.

I have before me a pianoforte with a register of seven octaves, containing wires which vary from about 150 cm. in length and more than 0·4 cm. in diameter to wires 10 cm. long and tightly stretched. If the range were continued to the eleven possible octaves the extreme dimensions would be proportionately modified, being lengthened in the one case and shortened in the other. This, I take it, is the best pianoforte manufacturers can do, and that if they could have used shorter or finer wires they would have done so.

Let us turn then to the human cochlea and form some idea of its dimensions relative to such an instrument. It consists of a tube coiled two-and-a-half times, about 35 mm. in length, and varying from 4 mm. to 1 mm. in diameter. The total cubic contents of the cochlea, according to Sir Arthur Keith, are 70 cubic mm. The third canal of the cochlea has a diameter varying from 0·5 mm. to 0·8 mm. The basilar membrane has, according to Keith, a diameter varying from 0·17 mm. to 0·4 mm., with an average area of 13·2 sq. mm.

If the cochlea as a whole be considered, it can be likened in size to a stout silk thread 35 mm. in length. If the third canal of the cochlea alone be considered it can be likened to a silk thread 35 mm. in length, with an average width of 0·5 mm.

How is it possible to imagine structures of this order of magnitude capable of differential resonance to the vibrations of sound? From the ability of the investigators who have been dealing with the problem, I am certain that such an elementary difficulty cannot have escaped them for a moment, but I shall be grateful to any physicist who will throw light on a problem which is as difficult as it is fascinating. If the presence of anatomical resonators capable of responding to vibrations of the varying length indicated can be demonstrated, the resonance theory can well be considered. Otherwise it must be abandoned.

JAMES W. BARRETT.

105 Collins Street, Melbourne,
January 5.

SIR JAMES BARRETT'S letter expresses a difficulty in the way of acceptance of the resonance theory which I believe to be more generally felt than perhaps any other, namely, the difficulty of conceiving that a structure so minute as the cochlea, which may be compared in size to a small split-pea, can contain a series of resonators capable of responding to some 4000 separate tones extending over about 11 octaves. When we compare the suite of strings of a piano, which will respond only to 85 separate tones in 7 octaves, although they occupy with their case a space of 10 to 15 cubic feet, and weigh several hundredweight, the whole conception seems indeed bizarre and absurd.

This difficulty may be considered under two headings:

(1) How to account for the minuteness of the scale.

(2) How it is possible to have such a wide range of tones within so small a cubic space.

(1) *Scale.*—If it be granted that we are to look for our resonating elements in the transverse fibres of the basilar membrane, the scale of the cochlea will be determined by the length of these fibres. This again will be determined by the formula

$$\text{Number of vibrations per sec.} = \frac{1}{2 \times \text{length of string}} \sqrt{\frac{\text{tension in dynes}}{\text{mass of unit length of string}}}$$

or

$$n = \frac{1}{2l}\sqrt{\frac{t}{m}}.$$

It is obvious that in this formula, for any particular value of n, l can be given any value we choose by assigning suitable values to t and m. Theoretically, there is no reason why the resonators should not be 10 or even 1000 times smaller than they are in the cochlea. Practically, the limits of what is possible are set by the strength, fineness, and flexibility of the materials available. The particular factor which renders this extraordinary reduction of scale possible is, that in the cochlea the factor m is large out of all proportions with what obtains in any of our stringed instruments. This result is attained by the beautiful mechanical device of loading the strings each with a definite mass of cochlear fluid.

(2) *Differentiation.*—The fibres of the basilar membrane are differentiated for length, tension, and mass just as are the piano strings. Accepting Keith's measurements, the differentiation for length is sufficient to account for 1½ octaves; that for mass (as determined by the "fluid load") for about 2¼ octaves. The remaining six to seven octaves of the audible scale must be due to variations of tension, as applied by the spiral ligament. This means a proportion of something like 1 to 5000 or 10,000 between

the lowest and highest tension. In a good section of the cochlea the spiral ligament will be seen to exhibit a progressive differentiation in bulk and closeness of texture not inconsistent with such extremes of tension. Further, the upper and lower limit of tension can be roughly calculated, and the resulting values are possible ones. The highest is only about a quarter of the breaking strain of tendinous structures of the same fineness.

Helmholtz recognised quite clearly the bearing of the "load" on the basilar fibres in rendering possible the small scale of the cochlea, though he failed to realise the *progressive differentiation* of the fibres for mass thereby effected. He says, "That such short strings should be capable of corresponding with such deep tones must be explained by their being loaded in the basilar membrane with all kind of solid formations; the fluid of both galleries in the cochlea must also be considered as weighting the membrane, because it cannot move without a kind of wave motion in that fluid" (second English edition translated by A. J. Ellis, p. 146).

No doubt if Helmholtz had known the anatomical structure of the spiral ligament, which was described by Albert Gray in 1900, the whole mechanism of the cochlea would have been clear to him.

Stirling's Theorem.

IN starting from $dn = 1$ and then making dn infinitesimal, Dr. Satterly's demonstration in NATURE of February 17, p. 220, is scarcely convincing, and the error introduced by this step is represented in his answer by the absence of the factor $1/\sqrt{n}$ or the term $\frac{1}{2}\log n$, neither of which is entirely negligible when n is large. I suggest the following adaptation of his proof, which avoids, I think, the inconsistency referred to above.

$$\text{Log } \underline{|n+1} - \log \underline{|n} = \log\,(n+1).$$

$\therefore$ by Taylor's theorem

$$(\text{D} + \text{D}^2/\underline{|2} + \ldots)\log \underline{|n} = \log n + 1/n + \ldots$$

all terms on the right being negligible after the first when n is large.

$$\therefore \log \underline{|n} = \frac{1}{\text{D} + \text{D}^2/\underline{|2} + \ldots}\log n$$

$$= \frac{1}{\text{D}}(1 - \text{D}/2 + k\text{D}^2 +)\log n$$

$$= \int \log n\, dn - \tfrac{1}{2}\log n + k/n + \ldots$$

$$= n\log n - n - \tfrac{1}{2}\log n + \text{C}.$$

The constant can readily be evaluated by the use of Wallis's expression for π.

Echinoderm Larvæ and their Bearing on Classification.

THOUGH loth to prolong this discussion, I wish, in fairness to Dr. Mortensen and myself, to say that I did not accuse Dr. Mortensen of regarding the echinoderm metamorphosis as a case of metagenesis. What I did write in NATURE for December 8, 1921, seems to agree entirely with Dr. Mortensen's statement on March 10, 1923—a statement accepted by Prof. MacBride.

Against Dr. Mortensen's view, that the sucking disc of Brachiolaria is a relatively recent acquisition, Prof. MacBride would cite me as in substantial agreement with himself (NATURE, January 13). That agreement extends to our common belief that all groups of echinoderms have passed through a fixed stage at some time in their ancestral history. On the precise relation of that fixed stage to the adult structure in the case of the starfish, we do not agree. Dr. Mortensen, it appears, is one of those who support my particular view. The sucking disc of the Brachiolaria has certainly been regarded by me, as by Prof. MacBride, as confirmatory evidence of the general theory. But if, as Dr. Mortensen now suggests, it be a secondary development, the theory does not necessarily fall, and Dr. Mortensen distinctly says that it does not. On the other hand, assuming Dr. Mortensen to be correct in his assertion that the forms with such a larva are only the more specialised, the sucker may none the less perpetuate an ancestral structure.

Until the geological history of the starfishes has been more fully worked out along the lines followed by Dr. W. K. Spencer, it is safer to express no opinion on the classification of the forms now living.

Constitution of Black Maketu Sand.

WE have made a careful chemical and X-ray analysis of the black sand from Maketu, N.Z., from which Dr. Alexander Scott believed he had isolated the oxide of a new element. We are able to confirm Prof. Bohr's conclusion that no new element is present.

Starting with 1000 grams of the sand we obtained 1·7 grams of material free from silica, and insoluble in sulphuric acid. Fusion with sodium bisulphate did not bring this into solution, thus confirming Dr. Scott's experience, but it is interesting to note that on fusion with *potassium* bisulphate the residue went into solution completely, and was found by both chemical and X-ray analysis to consist of about equal parts of iron and aluminium. Prof. Bohr found an appreciable quantity of titanium in the residue, while we found no more than a trace; but as our residue was only 0·2 per cent of the ore our extraction was probably more complete.

Scientific Periodicals for Czech Students.

I HAVE recently received a most earnest and pathetic request from a group of Czech students at the University of Prague asking me whether this Society could send them an English scientific periodical. Unfortunately we have no funds for this, but it has struck me that it might be possible for some of your subscribers, who perhaps do not have their copies of NATURE bound, to let me have them to send to these students. It would be a really kind and charitable act, and would be helpful in promoting the good feeling between ourselves and the Czecho-Slovaks, which is so useful at the present time.

If the papers were to be sent from London, I could arrange to call for them at stated times, so that no trouble of packing or postage would be involved.

The Egyptian World in the Time of Tutankhamen.

By Dr. H. R. HALL.

THE name of Tutankhamen, king of Egypt, whose reign may with comparative certainty be placed in the decade 1360–1350 B.C., is now a household word, and is probably known to many who have never heard of Thothmes or Rameses. The discovery of his tomb at Thebes by Lord Carnarvon and Mr. Howard Carter, with its wealth of funerary furniture and the magnificent state which probably enshrines the actual body of the king, has made Tutankhamen familiar to all; so that, at any rate for the time, we regard him as the typical Egyptian pharaoh of his age. But, as a matter of fact, he was an ephemeral and undistinguished monarch personally, and his short reign is only remarkable for one fact, the return of Egypt to the polytheistic faith of her forefathers after the short episode of the Disk-worshipping heresy of his father-in-law, Akhenaten, the artist, poet, and pacificist, one of the most extraordinary figures of the ancient world.

Akhenaten is the outstanding figure of his century, but he, again, is not the typical great king of his time: it is his father, Amanhatpe or Amenhotep III., the Memnon of the Greeks, who can rightly claim that position. Akhenaten was too strange and unconventional a figure. Tutankhamen began by following the heresy of his father-in-law, but in his day the reaction came, and the great god Amen of Thebes, king of the gods and head of the imperial pantheon, returned to his own. It is probably on this account that Tutankhamen was buried in the magnificent splendour that we see: Amen-Ra and his triumphant priests saw to it that the returned prodigal received fitting burial, with all the provision that the old religion could give him to ensure his dignity and well-being in the next world.

It is at the moment of his return to the national religion's fold that we survey the state of the world as known to the Egyptians, for to go further afield would bear us into endless paths of speculation. Egypt and Mesopotamia give us the only known chronological bases for real history at this time; to go outside their world, into the Bronze Age of Western Europe, for example, would be to cast loose from the control of known dates and events and to speculate merely as to the probable growth of civilisation, not to write history.

What was the world like outside Egypt, as known to the Egyptians, in Tutankhamen's day?

About 1580 B.C. the Syrian and Canaanite invaders who had dominated Egypt for at least two centuries, the Hyksos or Shepherd-Kings, had been expelled by force, and the Egyptians, filled with the spirit of *revanche*, had in their turn imposed their rule on the lands of their oppressors. The raids of the earlier kings of the XVIIIth Dynasty, which now occupied the throne of Thebes, had crystallised under Thutmases, or Thothmes, III. into a settled policy of conquest and empire, and Amenhotep III. was the undisputed ruler of Syria, Palestine, and Phœnicia.

These countries were regarded by the kings of Babylon and Assyria as the rightful domains of the king of Egypt, their peoples as his subjects. He was their lord in peace and war. Egyptian residents and generals controlled the native princes. The Egyptian frontier ran from the Amanus and north of the Aleppan district to the Euphrates near Carchemish, and thence down the river for some distance, till it turned off and ceased in the undefined wastes of the desert, reappearing at the head of the gulf of Akabah, in the land of Edom. The great historical cities of Syria, Aleppo, Carchemish, Damascus, and Jerusalem; the Phœnician cities of the coast from Arvad in the north, past Byblos, of old an Egyptian centre, Tyre, and Sidon to Akko in the south; the towns of the Philistine coast, from Dor to Gaza; had already existed for centuries. But though the Phœnicians were there, the Philistines were not yet in the land which afterwards bore their name, Palestine. They did not arrive in Canaan till nearly two centuries later.

Outside the Egyptian border to the west, in the days of Amenhotep III., the ancient kingdom of Babylonia existed in august but somewhat faded and inert majesty, as old as Egypt and as proud, but weak and querulous, trusting to the power of old renown as her protection against attack rather than to warlike prowess. Officially she now bore the name of Karduniyash, an appellation given her by the kings of her foreign Kassite dynasty, a race of conquerors, probably of Indo-European origin, who had come from beyond the Zagros some four centuries before.

North of her, on the Tigris, was Assyria, also an ancient power, but younger; Babylonian in culture, but more purely Semitic in race; and rejecting the claim to suzerainty which Babylon sought to impose on her. To the west of Assyria was the ill-defined kingdom of Mitanni, the land of Northern Mesopotamia between the Khabûr, the Euphrates, and the mountains of Diarbekir, inhabited by an intrusive race of uncertain origin ruled by kings probably, like the Kassites, of Aryan origin.

Farther west, beyond Taurus, was the confederation of tribes of the Anatolian Hittites, who owed allegiance to an overlord, the "Sun" of Khatti, reigning in central Anatolia, at a city represented by the modern Boghàz Köi, east of the Halys. The ancient Semitic population of Cappodocia no longer existed, having been destroyed or expelled by the Hittites.

Hittite tribes had already crossed the Taurus, inhabited the districts of Aleppo and Carchemish, and had even pushed outposts down as far south as Palestine, where they lived under Egyptian rule, side by side with the Canaanites and with Aryans from Mitanni.

South of the Anatolian Hittites was Cilicia, inhabited by a kindred race, of whose culture we know little, but that it owed much, probably, both to the Hittite and to the Syrian.

The island of Cyprus, the people of which also were racially related to the Anatolians, probably, had recently been conquered by Ægean tribes from Rhodes and Greece itself, who brought with them the Mycenæan culture, now beginning in Greece to take the place of the Minoan civilisation of Crete from which it was derived. The Minoan civilisation was now eclipsed on account of the collapse of the dominion of Knossos, which had sent ambassadors to Egypt in the days of Thothmes III.

This was, leaving out of account the Sudan in the south and the wild Libyan tribes to the west, the world as known to the Egyptians. Of Italy, they probably had as yet no knowledge.

Towards the end of the reign of Amenhotep III. a revolution broke out in Syria and Palestine. Shubbiluliuma or Suppilulius, king of the Hittites, a monarch full of guile, aspired to oust Egypt from the control of Syria and to destroy Mitanni. He found tools ready to his hand in certain discontented and rebellious Amorite princes of the Lebanon and in the Phœnicians of Arvad, and stirred up strife. Amenhotep quelled the revolt for a time, but it broke out again, and when his extraordinary son, Akhenaten, ascended the throne, the whole country seethed with turmoil.

The new king was interested only in his project of reforming the Egyptian religion; he was a man of art and of peace, and for the first time in history, perhaps, a great king refused to go forth to war, and allowed his dominions to fall away from him.

Palestine and Syria were in chaos. Wandering tribes, among them those Khabiri who have been credibly identified with the Hebrews, overran the land, the Hittite princes of the south revolted, and with them certain chiefs of Aryan (? Mitannian) origin who also had settled there under the Egyptian dominion. The Canaanite chiefs and Phœnician princes who remained faithful were gradually borne down in the absence of help from Egypt, and at the end of Akhenaten's reign the whole country had fallen away from the king.

In Tutankhamen's day the great prince Huy may represent himself on the walls of his tomb, as he does, bringing Semitic chiefs to offer tribute to his majesty, but we see that this can have been but a farce: the king's writ ran no farther than the coast of the Shephelah, probably. In the north the Amorites had but exchanged one master for another, for they now became the vassals of the Hittites, albeit under a looser control than that of Egypt. The Hittite control of Syria continued unchallenged till the days of Seti I. and Rameses II., fifty years later, when Egypt essayed to reimpose her yoke on the Semites. Long wars ensued, waged directly by Egypt against the Hittites, until about 1279 B.C. a peace of exhaustion was concluded between the protagonists, a peace of which we have the full protocol, signed and sealed by the Great King of Egypt and the Great King of Khatti, couched in diplomatic and legal phraseology that might have issued from a modern chancellery. It was a compromise: of her old Asiatic dominion Egypt retained only Palestine; Syria fell to the Hittites and remained theirs till, eighty years later, the invasion of the Philistines and their seafaring allies from the North overthrew the Hittite kingdom and tore Palestine itself from Egypt.

Tutankhamen, then, was confronted across his attenuated frontier by a far more formidable foe than the Babylonian could ever be. Mitanni was gone—destroyed by Shubbiluliuma after all help from Egypt had proved vain. Assyria, trusting in the prowess of her soldiers, kept her independence of both Babylon and Khatti; Shubbiluliuma seems prudently to have let her be. Her king, Ashur-uballit, was a long-lived and probably a politic as well as a doughty ruler. Somewhat later, in the time of Rameses II., Shalmaneser, king of Assyria, was a much more powerful monarch than the Babylonian Kadashman-turgu, and it was partly in apprehension of his power, probably, that Rameses and Khattusilis, the Hittite ruler, finally compromised their differences.

The collision of different national civilisations at this time produced none of the mutual approximations that might have been expected. Only Egypt began to show signs, more accentuated later, of Semitic influence in her culture. Babylon, however, shows no signs of Egyptian influence, the Hittites perhaps a little, the Mycenæans more. But there is no landslide in any direction anywhere. Each people remained faithful to its traditions. There were colonies of Mycenæan artists, as of Semitic and even Hittite craftsmen in Egypt. But though the Egyptians prized and used Greek products, we find no direct imitation of Minoan art even in the free and untrammelled Egyptian art of Akhenaten's time, though the works of the Minoan artists must have appealed to the realistic and truth-loving king. There is no trace of Minoan or of Mesopotamian influence yet in any of the objects of Egyptian art discovered in Tutankhamen's tomb of which photographs have been published: the weird heads, for example, of one of the gilded couches that have been thought to be Mesopotamian in aspect are merely heads of the Egyptian goddess Thoueris in her fierce and typhonic character. We should, in fact, expect Mesopotamian influence less than Minoan or even Hittite. The Thoueris-head was adapted by the Minoans for the heads of their water-demons.

Such, in brief survey, are the main characteristics of the outer world known to Tutankhamen and his people, and of Egypt's relations with it.

Recent Advances in Photographic Theory.[1]

By Dr. C. E. K. MEES.

THE study of the physico-chemical relations on which depend the form in which a precipitate is produced has been developed by a number of workers in recent years, and its application to the precipitation of silver halide has been studied by Sheppard and Trivelli. In his earlier work Trivelli made a large number of photomicrographs of emulsions taken from standard photographic plates and films, one of which is reproduced in Fig. 1. It will be seen that the silver bromide grains, of which the emulsion is composed, are of very varied sizes, there being present a large number of small grains, down to the limit of those visible with a microscope, and a smaller number of large grains, including some of very much greater area than the smallest grains present. The largest grains are all polygons, with angles of 60° and 120°. There is a tendency to round off the corners and edges of the small grains, so that the smallest grains appear to be more or less spherical.

[1] Communication No. 165 from the Research Laboratory of the Eastman Kodak Company. From a lecture delivered before the Franklin Institute of Philadelphia on December 7, 1922.

A study of these small spherical grains by R. B. Wilsey, however, using the methods of X-ray crystal analysis, shows that even the smallest grains are still definitely crystalline and have the same structure as the large grains, the crystalline form being a cubic lattice.

So long ago as 1915 it was realised that the distribution of the different sizes of grains in an emulsion might play a very important part in determining the characteristics of that emulsion. The problem was to measure the distribution of the grains; that is, the number of grains of a given size which occurred in an emulsion and the variation of the number with the size of the grain. This problem has often arisen in scientific work. It has been studied in connexion with suspensions of all kinds. Various indirect methods of attacking the problem have been suggested. It is possible to get determinations by settling the emulsion, taking advantage of the fact that the larger particles will settle most rapidly according to Stokes's law, but the direct method is, clearly, to spread out

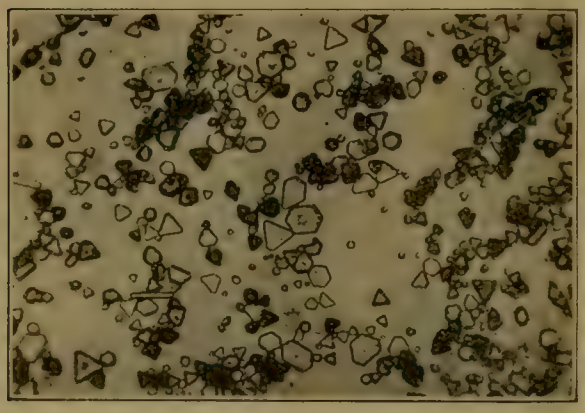

FIG. 1.

a thin layer of the emulsion and to count the different sizes of grains occurring in it. Trivelli photomicrographed a thinly coated emulsion at an enlargement of 2500 diameters, enlarged the negatives to 10,000 diameters, outlined all the grains of these enlargements, and then planimetered the grains and obtained tables showing the areas of the different grains present, at least a thousand grains being counted for each emulsion. Sheppard and Wightman obtained the same results by the use of the camera lucida instead of photomicrography. From these tables curves were obtained showing the relation between the size of grains and the number present for several standard emulsions. Fig. 2 shows the results for the portrait film and slow-lantern emulsions. It will be seen that the curve shows a distribution of sizes of grain which corresponds approximately to a probability curve, the maximum number of particles being of a diameter of approximately 0·5 μ, the particles both smaller and larger than this being fewer, until we have very few particles indeed of larger size than 2·7 μ and also few of smaller size than 0·2 μ. On this small side no particles can be measured less than 0·2 μ, because this is the limit of the resolving power of the microscope.

It is probable, however, that curves showing diameters will not be of real value, because the controlling factor will not be the diameter of the particles, but their projective area, as shown in Fig. 3.

Svedberg investigated systematically the relation between the size and sensitiveness of grains in photographic emulsions. He prepared emulsions so thinly

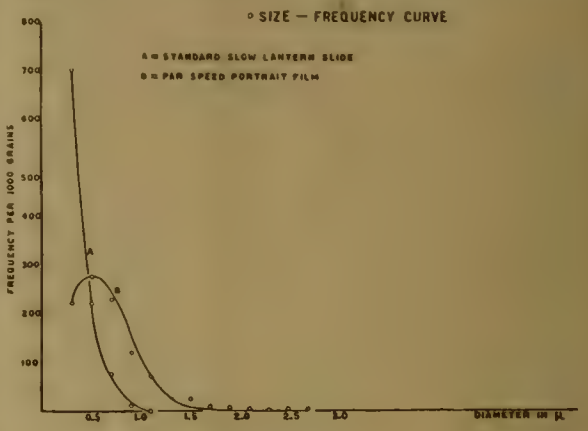

FIG. 2.

coated that the grains were all in single layers, and counted the grains of different sizes by classifying them into four classes. The emulsions were then exposed and developed, and the developed silver removed, the remaining grains, representing those which had not been made developable by the action of light, being counted. In this way curves could be obtained showing the sensitiveness of the grains of each class, and it was found, as might be expected, that the larger grains were much more sensitive than the smaller grains.

Svedberg next assumed that the product of the light action in the halide grain—that is, the substance of the latent image—consists of small centres distributed

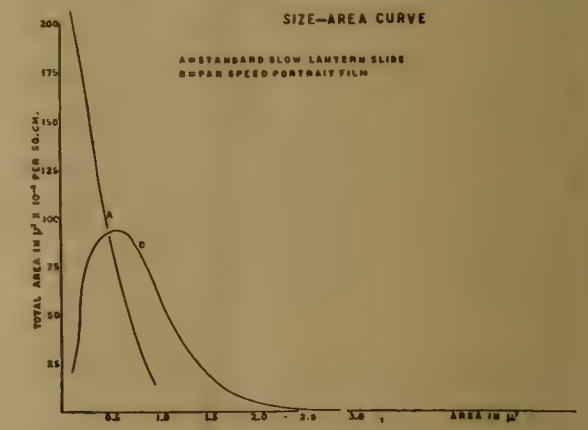

FIG. 3.

through the grain or through the light-affected part of the grain, and that these centres are distributed according to the laws of chance. If a plate be developed for a very short time the grains show these centres as small black spots upon them. This was shown by Hodgson as early as 1917 (Fig. 4).

Not only did Svedberg demonstrate the existence of these centres, but he also made plain their relation to the silver bromide grains by photographing the grains

before development by deep red light, then developing for a short time and removing the undeveloped halide. On the plate there are then left small dots, and comparisons with the first plate showed these to correspond with the silver halide grains originally present.

Svedberg has shown that the number of centres produced in this way by initial development increases with the exposure in accordance with the usual photographic laws, and it might be assumed that the discovery of these centres produced during development is a proof of discreteness in the action of light upon the grain, and that they must result from a structure in the silver bromide grains existing either before exposure or produced during exposure, and corresponding, for example, to spots of sensitiveness. While the evidence for this seems very great, it must be remembered that we know nothing about these centres until development takes place, and that even if the whole grain were equally affected by the action of light and changed to the same extent, we should still expect development to take place first at some local

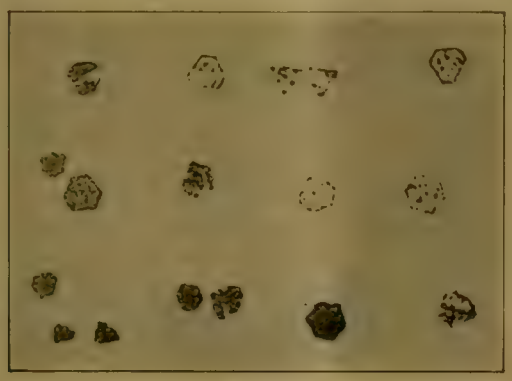

FIG. 4.

spot corresponding to slight surface differences in the grain. A sheet of metal immersed in acid, for example, will not be attacked uniformly all over the surface. Because of the impurities, action will start at individual points.

In a very important paper, Toy has given measurements showing that the number of nuclei produced on initial development are proportional to the number of grains which become developable on complete development, and that the larger grains not only have more nuclei on account of their size, but that these nuclei are also more sensitive to light than those in the smaller grains, the sensitivity of a grain being the sensitivity of its most sensitive nucleus. Svedberg considers that the number of developable centres per unit area of grain surface is a measure of the light sensitivity of the silver halide of the emulsion. From Toy's work it would seem to be doubtful whether we can speak of the light sensitivity of the halide itself in terms of the nucleus theory, since this will vary with the size of the grain.

Recently, a number of phenomena have been observed which are very difficult to explain by the use of the classical wave theory of light, and it seems not unlikely that it may be necessary to turn to a theory having some analogy to the corpuscular theory. As a first step towards this, Max Planck suggested his now well-known quantum hypothesis, according to which an atom radiating energy liberates it in discrete quanta, the amount of energy corresponding to each quantum being a constant multiplied by the frequency of the light. Bohr adopted Rutherford's theory of the structure of the atom, considering the atom to consist of a nucleus containing an electron carrying a positive charge of electricity, and to be surrounded by one or more electrons carrying a negative charge, the electrons revolving about the positive nucleus itself. He imagined that the electrons revolve without radiating, but that when an electron suffers some violent shock it gives up energy, and this energy is radiated and has the value of Planck's quantum. Thus, if an electron, by the sudden impact of another electron, for example, is thrown out of an atom and is attracted back to its place by the nucleus, then, as it falls back, it will send out a pulse of energy, and it will be seen at once that, if light is produced by such a behaviour of electrons, it is inherently probable that it will be radiated in pulses rather than continuously. Since, according to Bohr, the frequency of the vibration emitted is exactly proportional to the energy which the electron releases, Planck's quantum condition is fulfilled, and we have the famous equation,

$$Ve = h\nu,$$

where V is the voltage acting on the electron charge e, ν is the frequency, and h is Planck's constant.

In an X-ray tube the discharge of electricity is in the form of a stream of corpuscles travelling with a very high velocity, which depends upon the voltage of the electric current applied to the tube. When these corpuscles strike the target their energy is radiated in the form of X-rays, and we know that these X-rays partake very closely of the nature of light, except that the length of the waves is about one-thousandth of those of light, or, what is the same thing, their frequency is a thousand times as great. It is to this that they owe their great penetrating power.

On the classical wave theory of light, then, we should imagine that an X-ray tube having its target bombarded by the stream of corpuscles produced by the current would emit waves of X-rays spreading into space, just as waves of light are imagined to spread from a source; but now comes a great difficulty. When these X-ray waves travelling out pass through a gas and are absorbed, they cause the molecules of the gas to emit electrons, and these electrons are emitted with almost exactly the same velocity as the electrons in the tube which produced the X-rays themselves. The extraordinary nature of this phenomenon is well illustrated by Sir William Bragg in a recent article. He takes as an analogy the dropping of a log of wood into the sea from a height of one hundred feet. A wave radiates away from where it falls; the wave spreads; its energy is more and more widely distributed; the ripples die away; at a short distance, a few hundred yards, perhaps, the effect will apparently disappear. If the water were perfectly free from viscosity, and there were no other causes to fritter away the energy of the waves, they would travel indefinitely, always diminishing in their height. Now, at some point, say a thousand miles away, these now

microscopic ripples encounter a wooden ship. We should expect that they would produce no effect, especially as they may have passed many other ships without having affected them, but, for some reason, as these tiny ripples reach the ship, a plank of the same weight as the log is hurled out of the ship to a height of exactly one hundred feet, and the whole energy which was originally supplied by the log falling into the water is concentrated upon the ejection of the plank. It will be seen at once how inadequate the wave theory is to account for this phenomenon. Similar difficulties occur in connexion with photo-electricity or the liberation of electrons under the influence of light.

The method by which a photographic emulsion adds up light during a long exposure has always been a great problem when it is considered from the point of view of the classical wave theory. If we accept the idea that the grains of silver halide in an emulsion are exposed to a continuous flood of light from a distant star, for example, then each grain must be imagined to be integrating light until it has received enough to make it developable. Since the exposure required in astronomical photography is frequently very long, we must consider that the grains continue to integrate the light for many hours, and it is difficult to imagine any mechanism which would enable them to do this. The difficulty is enhanced by the fact that even a very brief exposure continues to produce an effect after an interruption of a long period, so that if all the grains have been affected by the first exposure, they must be capable of storing energy quite insufficient to make them developable and to hold this energy for a long period, and then resume its accumulation at the level where the interruption occurs. In the same way, when we study the exposure of the individual grains, even if we could imagine some mechanism by which the grains could store up the energy falling upon them until they became developable, we should expect that all the grains of the same size would become developable at the same time, unless, indeed, we assume the process of exposure to be autocatalytic in nature. When grains are examined under the microscope, however, some of them are found to have been affected before others. If we imagine that they all have become exposed to a uniform flood of light, we must consider that these grains differ in sensitiveness among themselves, and that the possibility of change on exposure, so that they become developable, is due to the presence of a sensitiser. This may be either concentrated unequally in the different grains or may form centres of sensitiveness similar to those supposed to exist by Svedberg and other workers in the field, who think that the centres found at the beginning of development are the origin of sensitiveness, and are present from the time of making the emulsion.

If we had no prior knowledge of the wave theory of light, however, it is clear that the simplest explanation of the sensitiveness of different grains would be that, instead of a continuous flow of light in the form of waves on to sensitive films, the light was falling upon it as a rain of projectiles, and that these projectiles made developable any grains that they hit, the grains that were missed not being developable, but being hit later if they continued to be exposed to the radiation. Naturally, the bigger the grains the more likely are they to be hit, so that a calculation can be made of the relation between the size and the percentage number of grains which will become developable after a given exposure.

Silberstein suggests that the projectiles, rather than being called "corpuscles," which gives the idea that they are round, should be called "light darts," and should be imagined to consist of a long train of waves of very small diameter travelling with the velocity of light.

It is obvious that this theory of light darts would meet the difficulties which are offered by the phenomena of X-rays and photo-electricity to the idea of a continuous wave front, while not excluding the possibility of the formation of interference and diffraction effects. At first sight it would seem to offer a solution of the problem of the integration of exposure by the silver halide grains of the emulsion, since we might assume that, instead of a grain integrating energy falling upon it until it had received enough to make it developable, it was not affected at all until struck by a quantum of light, and then became developable completely. If this was so, however, we should expect that the amount of energy necessary to make a grain developable would be, on the average, one quantum, and at most a few quanta, more than one being necessary because of the chance that a fresh grain would not be struck by every "light dart" falling upon the emulsion, some falling between the grains and others striking grains which were already developable.

In some work which has just been started in our laboratory we are getting results from which I think we may conclude as a preliminary statement that, for high-speed emulsions, several hundred quanta of violet light are necessary per grain in order to make the grain developable. If this is confirmed, the light dart hypothesis would seem to be scarcely sufficient by itself to explain the integration of energy by the emulsion, and we are thrown back on to the idea of differential sensitiveness among the grains, or of spots of limited area on the grains, so that of the hundreds of quanta striking a grain only one may be considered to be operative, the rest falling upon the insensitive portions of the grain. Suppose that the fraction of a grain which is sensitive is ϵ, and this consists of an average of $\bar{K}$ spots of ω area, then

$$\bar{K}\omega = \epsilon a.$$

Now, if a grain has no spots, it will be quite insensitive and will not be developable, no matter how long it is exposed, so that the value of $\bar{K}$ and ω can be determined experimentally by counting the grains left over after a very prolonged exposure.

In any case, a question of great importance in connexion with the latent image is the amount of energy required to make the silver halide developable. If the new determinations show that several hundred quanta of violet light per grain are necessary, then a revision of ideas relating to the latent image itself will follow, as compared with those ideas derived from the belief that the energy available is only one quantum per grain, in which case it is clear that the latent image must depend upon a change occurring in a single atom of silver or

halogen, since the only work we can imagine one quantum capable of doing is to release a single electron from an atom. If several hundred quanta per grain are available, then it is clear that not one atom of silver per grain may be affected, but that several hundred atoms may be changed, and that an appreciable, though very small, amount of chemical decomposition may be effected by the energy available.

More important still, quantitative differences in the amount of latent image present in a grain become possible. If only one quantum per grain is available, a grain is either exposed or not exposed, but if energy corresponding to an amount of several hundred quanta is used, we might imagine that a grain could become partly exposed, so that, for example, it might be developable by a developer of high reduction potential but not by one of lower potential. Moreover, grains might clearly be of different degrees of sensitiveness—that is, they might require different amounts of energy to make them developable—and the whole idea of quantitative differences in sensitiveness and exposure, which is so difficult if we imagine one quantum of energy per grain to be sufficient to produce a complete change in the grain which will make it developable, becomes perfectly intelligible. On the other hand, the division of the sensitive area into a number of small sensitive spots, which accords with the ideas both of Silberstein and those of other workers such as Svedberg who have located sensitiveness in "centres," would still enable us to retain the idea that a single quantum of energy is sufficient for exposure if it reaches one sensitive spot.

Obituary.

DR. JAMES GOW.

THE lamented death on February 16 of Dr. James Gow, formerly headmaster of Westminster School, and author of "A Short History of Greek Mathematics," calls for notice in NATURE. Educated at King's College School, Gow went to Trinity College, Cambridge, in 1871, and was 3rd Classic and Chancellor's classical medallist in 1875. He was elected fellow of Trinity in 1876, the year in which it was observed as a curiosity that the four fellows of Trinity then elected all had monosyllabic names and mustered no more than fifteen letters between them: Cox, Hicks, Lord, Gow. Three of them, including Gow, rowed for the historic Second Trinity Boat Club, now extinct.

Gow's mind was alert, quick, and versatile; he could have succeeded at almost anything he undertook. The son of an artist, he had himself decided talent in the same direction; he was, as an undergraduate, devoted to music. But his main work was in classics, and even there his interests were very varied. His fellowship dissertation was on the origin of grammatical gender; he edited the Odes and Epodes and the Satires of Horace; and he produced one of the most useful books ever written for schoolboys, a "Companion to School Classics"—a pioneer work which gave a lead to more ambitious and bulky handbooks since issued from the University Presses and elsewhere.

The "Short History of Greek Mathematics" is another proof of Gow's versatility. His original intention was to write a history of the city of Alexandria. He contemplated a chapter in that work which should deal with the mathematical school from Euclid to Diophantus. But this project led him insensibly to more general mathematical topics, such as the development of numeral systems, Egyptian arithmetic, Greek calculation and Greek theory of numbers, with the result that the material accumulated became too extensive for a chapter in a more general history, and he decided to make Greek mathematics the subject of a separate work. Such a book was very much wanted; here, too, he was breaking new ground. There were three recent and important German works by Bretschneider, Hankel, and Moritz Cantor, but no book in English at all comprehensive. The undertaking was the more arduous in that Gow had made no special study of mathematics since his schooldays, and it is no small proficiency in mathematics that is required for the compilation of such a history. The work proved a little uneven owing to the fact that the arithmetical portion was written on a scale too large to allow of the history of geometry being treated with equal fulness if the whole work was to be in a reasonable compass; and Gow realised that with "a history like this . . . the utility will no doubt vary as the brevity" (p. 145).

The best possible test of a book is, perhaps, the impression that it makes upon a reader who takes it up thirty or forty years after its publication. This book stands the test well. It is true that the mass of the material that must be included appeared to Gow at times to be overwhelming; for he speaks in his preface of the labour having often been dreary. But this certainly would not be gathered from the finished work, which is from first to last anything but dreary. Many things in it have necessarily been superseded as the result of subsequent researches, but the book can still be read with the same pleasure as it aroused on its first appearance. T. L. H.

REV. WILLIAM WILKS.

HORTICULTURE is the poorer by the sudden death on March 2 of the Rev. William Wilks, vicar of Shirley, Croydon, 1879–1912. The son of Dr. G. F. Wilks, born at Ashford, Kent, on October 19, 1843, William Wilks was educated at Clapham and Pembroke College, Cambridge, where he took his degree in 1864. He was intended to follow his father's profession, but forsaking that course, after studying at Wells, he took orders, and was appointed curate of Croydon in 1866. The rest of his life, except for his annual holiday on the Continent, or latterly in Scotland, was spent in that neighbourhood, and when in 1912 he resigned his vicarage he went to live and garden next door at the "Wilderness" which he had built, and where he died.

There is no need to speak here of Mr. Wilks's parish work—the concourse of local people at his funeral at Shirley showed how it was appreciated—but rather

of his work in and for horticulture. For nearly sixty years he was intimately connected with the Royal Horticultural Society. His grandfather and father had both taken a keen interest in gardening at Charing and Ashford, and the curate of Charing, the Rev. J. Dix, for some time chairman of the Royal Horticultural Society's Floral Committee, was an intimate friend of his youth. His love of Nature and gardening was still further fostered by his education under Prof. Pritchard, and by his vicar at Croydon, Canon Hodgson, so that when he went to Shirley he was well equipped to follow his bent in the large garden of the vicarage. He became a member of the Royal Horticultural Society's Floral Committee about 1880, and at the great reconstruction of the Society in 1888 he was appointed honorary secretary. He filled the post of secretary until 1920, when he retired and was elected to the council.

In 1888 the Society was in very low water; its liabilities were great, its finances low; it had less a horticultural than a social policy; it seemed doomed to early wreck, after weathering the storms of eighty-four years. With its new secretary, Sir Trevor Lawrence, Sir Daniel Morris, Sir William Thiselton-Dyer, Sir Harry Veitch, Mr. George Paul, Sir Michael Foster, Dr. Masters, and others, a determined return to a horticultural course was made, and in steering that course William Wilks took a leading part. He was a great secretary. A man of wide vision, a fine judge of men, courteous, tactful, able to bend men and things to the policy the new council had determined upon, cautious but ready to seize opportunity, loyal to his council and inspiring loyalty, ready with encouragement, kindly in restraining excess of zeal, an able organiser, under him the Society progressed from potential bankruptcy to financial prosperity, from a membership of about 1000 to more than 16,000, to the possession of its fine hall and offices, its Journal (which he edited from 1888 to 1906), its great garden at Wisley, with its school of horticulture and the development of research into gardening problems which all along he had seen to be essential to sound progress, and which, as soon as finance permitted, he fostered with all his power. His aim all through was to further British horticulture in its widest sense, and for his work for the Society, until it had been placed upon a sound financial footing, he took not even the most modest remuneration. The Society to-day is a monument to his work.

The gardens of the world, large and small, even into the Arctic regions, are the richer for Mr. Wilks's own gardening efforts, for from an aberrant field-poppy he raised the wonderful strain of Shirley poppies, and freely distributed seed every year to all comers. As with his poppies and foxgloves, he deemed no pains too great to spend upon the selection and increase of beautiful hardy things, and no pleasure to exceed that derived from sharing his beautiful things with others. His writings in the Journal were of these things. In his quiet garden he grew the choicest of hardy fruits, for he was a pomologist of no mean order, and he cared for and studied there the plants and animals it contained and attracted, with all the love of a true naturalist.

Sir Ernest Clarke.

Sir Ernest Clarke, a man of singular ability, and gifted in many different directions, was perhaps best known as secretary of the Royal Agricultural Society of England from 1887 to 1905.

Himself a Suffolk man, born at Bury St. Edmunds in 1856, Clarke had a special interest in East Anglia, and contributed largely to the enrichment of its archæology, literature, and folklore. In especial he showed himself an adept in unearthing the truth and in demolishing many of the erroneous statements that had found their way into past records. This same power marked his treatment of agricultural history and literature when, as the first Gilbey lecturer, he gave, in 1896, his series of lectures at the University of Cambridge, from which, in 1894, he had received the degree of Hon. M.A. Indeed, one may say that he was the first serious student of this subject since Arthur Young.

After service in the Local Government Board, and then as assistant secretary in the Share and Loan Department of the Stock Exchange, Clarke was selected in 1887, out of 106 candidates, to be secretary of the Royal Agricultural Society of England in succession to the late H. M. Jenkins. As secretary of the Society he distinguished himself by his great activity and powers of organisation. He had great ideals as to the position which such a Society as his should occupy as the leading authority both at home and abroad, and such he worked constantly to make it. For more than eighteen years he acted in this capacity, receiving the honour of knighthood in 1898. Later, however, came the disastrous days (1903–6) arising from the decision of the Council to abandon the peripatetic Shows and to have a permanent Showground at Park Royal, and this resulted in Clarke's resignation in 1905. He then returned to the City, and was associated, to the close of his active career, with various commercial enterprises.

Following on the death of his wife in 1918, Clarke was struck down with a paralytic seizure, and for the last four years of his life was unable to leave his room. But he retained to the end the clearness of intellect, and the interest in all around him, that had marked his active days.

Though he could never be called an "agriculturist," Clarke contributed largely to its history and literature, and the Journal of the R.A.S.E. contains many admirable reports of his, chiefly memoirs of noted agriculturists, such as Philip Pusey, Sir James Caird, the Duke of Richmond, etc., besides the "History of the Board of Agriculture," "Agriculture and the House of Russell," etc. To the series of King's Classics he contributed, in 1903, a new edition of "The Chronicles of Jocelin of Brakelond," an account of monastic life in the days of Abbot Samson, and he made many other contributions to archæological, historical, and folklore societies. He was an original member of the "Confrères"; and one of the "Sette of Odd Volumes"—being the "yeoman" in that body, and president in 1898. He was also a past-president of the Chartered Institute of Secretaries. Clarke was, in addition, a gifted musician, a brilliant conversationalist, and a man of much reading and wide general knowledge.

J. A. Voelcker.

Current Topics and Events.

BY Clause 9 of the "Fees (Increase) Bill," the Government proposes to confer upon the Trustees of the British Museum a power which they have never sought and which, we are certain, they do not desire—a power to charge fees for admission to the Exhibition Galleries both at Bloomsbury and South Kensington. Of course, if the power is granted by Parliament, the Treasury will take good care that the Trustees exercise it. The precise proposal is to charge a fee of 6*d*. on Monday, Tuesday, Thursday, and Friday. How much better will anyone be for this? The probable receipts seem to us to be ridiculously overestimated by the Geddes Committee, since they only allow for a reduction in the number of visitors of less than one-half. Speculation on such a matter is rather idle. We know only that a charge of 6*d*. on three week-days at the Victoria and Albert Museum brought an average yearly return of 1000*l*. Against a possible income of, say, 1200*l*., have to be set expenditure on the installation of turnstiles and a considerable diminution in the receipts from the sale of publications, which has been greatly extended of late in both sections of the Museum. But this sort of haggling is beside the mark. The condemnation of this retrograde proposal depends on no nicely calculated less and more, but on the disservice that will thereby be done to popular education in its widest and highest sense. The nation will lose and the Museum will lose, for we may be sure that gifts in money and in kind will not flow so readily to a half-closed establishment. It seems, too, as though the Government would lose whatever popular support it now possesses. The British Museum has become in a very real and living sense a national possession, and the nation will refuse to be robbed of its free enjoyment.

THE reluctance to discuss the monetary value of their services is a tradition which dies hard among the brain-workers in this country and abroad, and is in large measure responsible for the unenviable position of many salaried workers during and since the War. In the legal and medical professions, which occupy a legalised privileged position and are further safeguarded by the needs and the attitude of the community, professional unity is possible and demands for improved conditions of service and better remuneration for these classes are generally successful. The success of medical men in this country in particular has given an impetus to other professional workers towards combination, and various organisations now exist having for their avowed object the improvement of the economic position of the professional classes. In France, after approaching first the Confédération Générale du Travail, and later the General Association of Employees—both organisations of manual workers—the brain-workers have decided to form their own independent Confédération des Travailleurs Intellectuels. It is already in a position to exert considerable influence in the Chamber of Deputies and the Senate, and its success has provoked the creation of similar bodies in several other European countries. In this country there is an organisation, the National Federation of Professional Technical, Administrative, and Supervisory Workers, founded in 1920, having similar aims. Hitherto it has not been able to obtain the support of the medical, legal, engineering, teaching, or scientific associations. These may join the federation later, but, in the first instance, they will probably find it better to form their own federation. The time is certainly opportune for a movement to be made in this direction.

THE sum of 1,000,000*l*. provided for agricultural research and education under the Corn Production Acts (Repeal) Act, 1921, has now been provisionally allocated for the furtherance of various schemes, and the details are outlined in the current issue of the Journal of the Ministry of Agriculture. The suggested grants cover a wide field, and in several cases are intended to be supplemented by certain moneys raised by the institutions benefiting therefrom. Dairying, silver-leaf research, and fruit growing are to be aided in various centres by the provision of building and maintenance funds, and a scheme is under consideration for the establishment of an Animal Pathology Research Station at Cambridge University. Support is also being given to the National Poultry Institute scheme, with special provision for research in various directions, for commercial experiments and for higher instruction in poultry keeping. On the educational side additions are being made to the research scholarships and travelling fellowships, the advisory services are to be completed and strengthened, while a considerable sum has been provisionally allocated for grants in aid of capital expenditure at university departments of agricultural colleges. County agricultural education will benefit in a similar way. The approximate allocation under the above headings is as follows: Research and Advisory work, 465,000*l*.; Higher Agricultural Education, 84,000*l*.; County Agricultural Education, 170,000*l*.; Scholarships for the sons and daughters of Agricultural workers, 117,000*l*.; Miscellaneous Schemes, 74,000*l*. Some re-arrangement of the above sums may, however, prove to be necessary as the schemes are more fully investigated and begin to be worked out.

THE Retail Pharmacists' Union, in a recent announcement with regard to the subject of the accurate dispensing of medicines, describes the training required for the profession of pharmacy. The announcement is, however, headed with the words "The Chemist," and this has led Mr. A. Chaston Chapman, president of the Institute of Chemistry, to suggest again that the time has come for the pharmacist to relinquish the use of the term "chemist" in favour of those who definitely practise chemistry. Mr. Chapman points out that "the Institute of Chemistry, as the representative chartered professional body of chemists, numbers upwards of 4000 fellows and associates, whose qualification demands a four years'

university course, or the equivalent, and the majority of whom are engaged in the many branches of industry on which the science has a bearing. In other countries the strict equivalent of the word 'chemist' signifies, as it should, one who professes chemistry, and not in any case the pharmacist, druggist, or dispenser of medicines."

THE summer meeting of the Institution of Electrical Engineers will be held at Manchester and Liverpool on June 5-8. Visits have been arranged to important electrical works in the locality.

A CONFERENCE of the Women's Engineering Society will be held at the University of Birmingham on April 11-14. Particulars can be obtained from the general secretary, Miss C. Haslett, 26 George Street, Hanover Square, London, W.1.

IN the new edition of Zittel's "Grundzüge der Paläontologie," lately published, Profs. Broili and Schlosser refer to the tooth of the supposed ape-man, Hesperopithecus, from Nebraska, U.S.A., as being a problematical specimen. They state that it may perhaps be the first milk-molar of a primitive horse.

THE Geological Department of the British Museum (Natural History) has just acquired the palæobotanical collection of Dr. Dukinfield H. Scott. It comprises more than 3000 microscope slides, chiefly of British Carboniferous plants, on which most of Dr. Scott's own researches have been based. It is a direct continuation of the Williamson collection which was acquired by the Museum in 1896.

IT is stated in the *Chemical Age* of March 10, that at the annual meetings of the American Chemical Society to be held next month, Prof. F. G. Donnan and Principal J. C. Irvine will be among the British delegates. The subjects for discussion will include motor fuels, the history of coal tar dyes, insecticides and fungicides, and the chemistry of cellulose.

IT is stated in a Press dispatch from Oklahoma City appearing in *Science*, that an amendment prohibiting the purchase of books or copyrights teaching the theory of the evolution of the human race was inserted in the State Free Text Book Bill which passed the lower house of the legislature on February 21. Only one dissenting vote was cast against the anti-Darwinian section.

THE Mueller medal and fund have been awarded to Mr. J. H. Maiden, Government Botanist of New South Wales and director of the Botanic Gardens, Sydney, in recognition of his botanical work. The medal was founded in memory of the late Baron von Mueller, Government Botanist of Victoria, and is awarded at each meeting of the Australasian Association for the Advancement of Science, which, in 1923, sat at Wellington, New Zealand. It has been awarded previously for botany, zoology, geology, and ethnology.

PROF. HORACE LAMB, late professor of mathematics in the Owens College and University of Manchester; Lord Meston of Agra and Dunottar, formerly Lieut.-Governor of the United Provinces of Agra and Oudh; and Mr. G. Gilbert Scott, Royal Academician, have been elected members of the Athenæum Club under the provisions of Rule II. of the club, which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public service."

A SYMPOSIUM and general discussion on alloy resistance to corrosion will be held at the Department of Applied Science of the University, Sheffield, on Friday, April 13. The meeting is being organised jointly by the Faraday Society, the Sheffield section of the Institute of Metals, and the Manchester Metallurgical Society, and the scope of the discussion will include the new non-corrodible, non-ferrous alloys, such as stainless nickel silver and the nickel chromium alloys, as well as stainless iron and steel. A general introduction to the discussion will be given by Prof. C. H. Desch. Further particulars may be obtained from Mr. G. R. Bolsover, Brown-Firth Research Laboratory, Princess Street, Sheffield, or from the secretary of the Faraday Society, 10 Essex Street, Strand, London, W.C.2.

FARMERS' Clubs, Chambers of Agriculture, and other bodies or individuals interested in agriculture are invited to visit the headquarters of the National Institute of Agricultural Botany, Huntingdon Road, Cambridge, during the coming summer. They will be able to see trials of new varieties of wheat and barley in progress on the trial ground, and a collection of different varieties of various farm crops growing in the field. The buildings of the Institute will also be open to inspection; these include the Official Seed Testing Station for England and Wales, where testing of seeds is always being carried out. The most interesting period for inspecting the Institute is from June to August, and all who wish to take advantage of the invitation should communicate with the director of the Institute, Mr. W. H. Parker.

MR. T. SHEPPARD, the energetic Curator of the Hull Municipal Museum, by the publication of a series of pamphlets describing the collections in his charge, has done much to popularise the study of science and archæology, and has given an example to those in charge of similar collections. A recent publication is a list of the specimens of natural history, antiquities, and applied art. The museum dates from 1823, and the specimens collected by the Literary and Philosophical Society finally passed to the Hull Municipal Museum in 1902. Since then the collections, particularly of local scientific objects and antiquities, have been largely extended, and the museum now holds a high place among similar institutions. Its value has been largely increased by Mr. Sheppard's continuous efforts to bring the collections to the notice not only of local visitors but of those from a distance.

THE British Non-Ferrous Metals Research Association has adopted a somewhat novel way of communicating the results of its recent investigations

to its members. Lectures are arranged at one or more centres to which only the members of the Association itself are admitted. Two objects are served in this manner: first, early confidential communication of the results of the research is assured to those who have given it financial support; and secondly, the investigator gets into close and immediate contact with that section of the industry chiefly interested in his work. This private lecture system has so far been applied to two subjects. Dr. W. Rosenhain has reported on the investigation on copper, and the influence upon its properties of small quantities of impurities, which is being carried out for the Association by Dr. D. Hanson and others at the National Physical Laboratory; and Mr. E. A. Bolton has described work on the cause and prevention of red stains on brass, which he is carrying out at the University of Birmingham.

THE Staff Association of the British Museum (Natural History) held, on March 8 in the Museum Board Room, a scientific reunion which was attended by about seventy members and visitors. Round the room were arranged a large number of interesting objects. Among the geological exhibits may be specially mentioned the portions of the fossilised skeleton of Baluchitherium, a gigantic perissodactyl ungulate from Baluchistan, recently described by Mr. Foster-Cooper. This species is closely related to the rhinoceros, and is the largest land mammal at present known. An exhibit of the fauna of submarine cables attracted much attention, particularly the portion of a cable, brought up from a depth of 750 fathoms, showing a shark's tooth broken off in the wire sheath. A series of mounted specimens of animals acquired by the aid of the Rowland Ward bequest were shown. The flattened crystal of diamond and the well-formed ruby crystal, both formerly in the John Ruskin collection, were on view. It being the intention of the Trustees to adapt a bay in the Central Hall for the purpose of displaying the South African elephant in its natural surroundings, Capt. Guy Dollman had prepared a model on a one-eighth scale to demonstrate the effect; artistically designed and executed and efficiently lighted, this model was exhibited, and proved very popular. Messrs. C. Baker demonstrated their most recent microscopes and accessories.

AN International Air Congress will be held in London on June 25-30 this year under the presidency of the Duke of York, when opportunities will be provided for the reading and discussion of papers on every aspect of air matters. The Congress will be divided into four groups (each again divided into sub-groups) which will meet simultaneously. Group A will deal with methods of research, aerodynamics, controllability, structural methods, materials, and alighting gear. Group B is subdivided into sections on fuels and lubricants, motive-power plant, air-screws. Group C will discuss air transport and navigation problems, and in Group D airship design and construction will be discussed. Further particulars can be obtained from Lt.-Col. W. Lockwood Marsh, General Secretary, International Air Congress, London, 1923, c/o The Royal Aeronautical Society, 7 Albemarle Street, London, W.1, England.

UNDER the title of "The Claim of Antiquity," the Councils of the Societies for the Promotion of Hellenic and Roman Studies and of the Classical Association have issued an interesting bibliography of books for those who know neither Latin nor Greek. It provides a list of the best books, originals or translations, dealing with the general subject of classical literature; the most important authors; philosophy and religion; history; geography; science; art and archæology; and social life, giving the prices of each publication. The volumes published in the excellent Loeb Library have done much to spread the knowledge of classical literature among those who are ignorant of or have forgotten their classical learning, and the present publication, compiled by experts, will do much to advance the objects which these classical societies have in view. It will furnish an acceptable addition to all school libraries.

THE Secretary for Mines invites applications for a research post under the Safety in Mines Research Board. Candidates must possess high general scientific qualifications and experience in engineering, with, if possible, a knowledge of coal mining. The person appointed will be required to advise on questions of research on the safety problems of coal mining, to prepare programmes of research, and to organise and superintend research work. Applications for the position must reach the Under-Secretary for Mines, Mines Department, Dean Stanley Street, S.W.1, by, at latest, April 30.

THE tricentenary of the birth of Blaise Pascal occurs on June 19, and preparations have been made for celebrations in France on July 8-9. The President of the French Republic will attend the meetings, the chief of which will be a commemoration gathering, to be addressed by the Minister for Public Instruction and other members of the French Academy. There will also be a meeting at the summit of the Puy de Dôme, when a member of the Academy of Sciences will speak on the famous experiment carried out there, at Pascal's suggestion, of observing the barometric height at the summit and comparing it with that at the base of the mountain. A difference of three inches in the height of the mercury column was observed, giving Pascal justification for his conclusion that the column of mercury in the barometer is supported by the pressure of the atmosphere.

AT the annual general meeting of the Geological Society held on February 16, the following officers and members of council were elected:—*President*: Prof. A. C. Seward. *Vice-Presidents*: Dr. J. W. Evans, Mr. R. D. Oldham, Dr. H. H. Thomas, and Prof. W. W. Watts. *Secretaries*: Mr. W. C. Smith and Mr. J. A. Douglas. *Foreign Secretary*: Sir Archibald Geikie. *Treasurer*: Mr. R. S. Herries. *Other members of council*: Dr. C. W. Andrews, Mr. F. N. Ashcroft, Prof. P. G. H. Boswell, Prof. W. S. Boulton, Dr. Gertrude L. Elles, Dr. J. S. Flett,

Dr. F. H. Hatch, Prof. O. T. Jones, Mr. W. B. R. King, Dr. W. D. Lang, Prof. S. H. Reynolds, Sir Aubrey Strahan, Sir Jethro Teall, and Mr. H. Woods.

AT the general meeting of the Asiatic Society of Bengal on February 7, the following officers and members of council were elected:—*President*: Dr. N. Annandale. *Vice-Presidents*: Sir Asutosh Mukhopadhyaya, Mr. Mahamahopadhyaya Haraprasad Shastri, Dr. J. Coggin Brown, and Lieut.-Col. J. D. W. Megaw. *General Secretary*: Mr. Johan van Manen. *Treasurer*: Prof. C. V. Raman. *Philological Secretary*: Dr. D. R. Bhandarkar. *Joint Philological Secretary*: Mr. S. Khuda Bukhsh. *Natural History Secretaries*: (*Biology*) Dr. P. J. Bruhl and (*Physical Science*) Mr. P. C. Mahalanobis. *Anthropological Secretary*: Ramaprasad Chanda. *Medical Secretary*: Major R. Knowles. *Honorary Librarian*: Dr. T. O. D. Dunn. *Honorary Numismatist*: Mr. C. J. Brown. *Other Members of the Council*: Dr. Upendra Nath Brahmachari, Mr. Kumar Sarat Kumar Roy, Sir R. N. Mookerjee, Mr. Pramatha Nath Banerjee, and Dr. W. A. K. Christie.

THE Australian National Research Council is making preparations for holding an important Pan-Pacific Science Congress in Australia in August next. The sympathy and support of the Commonwealth Government has been secured, and it is expected and sincerely hoped that scientific workers representing all the countries bordering, or having interests in, the Pacific will send representatives to this congress. Already the Commonwealth Government has issued cordial invitations to the countries concerned, inviting them to join in making this congress a success. It is well known that in international matters the Pacific must play an important part in the near future, and a fuller knowledge of its peoples, its products, and its natural phenomena, from a scientific point of view, is urgently desirable. The first Pan-Pacific Science Congress was held at Honolulu in August 1920, and it is proposed that the Australian meeting should be opened at Melbourne on August 13, 1923, and on August 23 be transferred to Sydney, and terminate there on September 3. Arrangements are being made to deal with the following subjects: (*a*) agriculture and veterinary science; (*b*) anthropology and ethnology; (*c*) biology, including botany, entomology, zoology; (*d*) geography and oceanography; (*e*) geology; (*f*) hygiene and climatology; and (*g*) physics, including geodesy, geophysics, radiotelegraphy, and seismology. Among the office-bearers are the following: Australian National Research Council—Sir David Orme Masson, The University, Melbourne (*President*); R. H. Cambage, Royal Society, Sydney (*Hon. Secretary and Treasurer*); Prof. A. C. D. Rivett, The University, Melbourne (*Joint Hon. Secretary*). Pan-Pacific Committee—Sir Edgeworth David, The University, Sydney (*Chairman*); E. C. Andrews, Mines Department, Sydney (*Hon. Secretary*).

THE projection of light in optical lanterns and kinema apparatus, discussed before the Illuminating Engineering Society on February 20, is a problem that evidently deserves more study. It appears from the results of recent tests that in most optical lanterns only about six per cent. of the light furnished by the source is usefully applied on the screen. In the kinema projector, with its small aperture and shutter, the percentage is even less. Moreover, even the light reaching the screen is not all profitably used, for much of it is reflected on to walls and ceilings and never reaches the eyes of the audience. Some attempts to utilise gas-filled incandescent lamps in place of arcs were also described, and the results of investigations seem fairly promising. Other items of interest in the discussion included a demonstration by Major Adrian Klein of his new colour-projector, and a three-phase alternating current arc shown by Mr. J. Eck. From a scientific point of view the Klein projector is particularly interesting, as the colours are not produced by means of filters, but by the aid of a train of prisms. When these spectrum colours are projected on painted scenery very vivid changes are produced.

THE annual report of the Meteorological Committee to the Air Council for the year ended March 31, 1922, has recently been issued. It is the sixty-seventh year of the Meteorological Office and the second report submitted to the Air Council instead of to the Treasury as formerly. The meteorological service now comprises many meteorological organisations which in past years have been carried on separately and independently. In all, the total staff aimed at to complete the organisation is 375. Retrenchments undertaken, however, by all Government departments have led to some modified programmes for the meteorological service, and reductions in the staff have taken place instead of the wished-for augmentation. The total whole-time staff of the Meteorological Office and its out-stations has changed during the year from 266 to 261. The year has seen a great increase in the interest of seamen in weather information, and the report mentions that it is greatly to be regretted that this increased interest should coincide with conditions which have made it imperative to reduce rather than to extend the activities of the Marine Division. Data now being received are gradually getting back to pre-war conditions, when it was equally felt that excessive observations were costly. For forecasting work the report states that, although certain messages are still received by cable, almost all European countries have now adopted the use of wireless telegraphy, and it is growing evident that it will shortly be possible to dispense entirely with the exchange of messages by cable. Much information is given relative to aviation and the upper air, new developments entailing much organisation. The British Rainfall Organization is now controlled by the Meteorological Office, and among many other branches of work may be mentioned atmospheric pollution and the oversight of attached and subsidiary observatories.

THE Journal of the British Science Guild for February contains a summary of the proceedings at the annual dinner in May last year. In proposing the toast of the British Science Guild, Sir Arthur

Mayo-Robson mentioned the interesting fact that Lord Curzon had distributed 500 prospectuses of the Guild's "Catalogue of British Scientific and Technical Books" to His Majesty's Consuls abroad. He also pointed out the thirst for scientific knowledge that was developing in various parts of the Empire he had recently visited, where fruitful opportunities for the work of the Guild appear to exist. Among others who spoke, Mr. H. G. Wells pleaded for a wide view of science, which should not be regarded as a monopoly for any nation, though they naturally hoped that the British Empire would make a worthy contribution to the general store of knowledge. The late Mr. F. W. Sanderson, whose genius as a schoolmaster is the subject of appreciatory editorial reference, emphasised the value of scientific methods in schools in developing a desire among boys to "get at the truth." He added that a catalogue of the British Scientific Products Exhibition had been of great interest to the boys. Other contributions to the journal cover wide ground. There are extracts from recent articles in the press on the Guild's national appeal. Prof. Flinders Petrie and Admiral Ballard have contributions on "The Science of Sailing." Dr. J. A. Harker deals with "The Fixation of Nitrogen," Mr. A. P. M. Fleming with "Radio-Telephony," and Mr. Leon Gaster with "Illuminating Engineering." Dr. R. S. Clay furnishes a note on "The British Pianoforte Industry." As usual the Journal also contains a series of readable notes illustrating the application of science in daily life.

COMMANDER HILTON YOUNG makes to us the suggestion that insects may be able to appreciate the proximity of a solid body by detecting the pressure differences which would be set up by air currents impinging on the latter. He asks whether this possibility has been examined, and a distinguished naturalist to whom we submitted the inquiry states that various entomologists have referred vaguely to insects being affected by changes of air pressure. Forel speaks of the sensitiveness of insects to slight movements in the air and to slight vibrations in his "Le Monde social des fourmis," vol. 2 (1922), and Folsom in his "Entomology" (1906) suggests that the sensillum placodeum may be affected by air pressure. Another work by Forel, "Sensations des insectes" (1886), and Berlese's "Gli Insetti," should also be consulted.

THE firm of Mr. C. Baker, of 244 High Holborn, London, W.C.1, has issued the January number (No. 77) of its well-known classified list of second-hand instruments and scientific works. The catalogue is arranged in sections, each confined to a specific class of apparatus, and contains a number of useful items. Those in need of physical apparatus, microscopes, cameras, etc., would do well to consult this list.

MANY students to whom Dr. A. Holmes's "Petrographic Methods and Calculations" is of interest and value will be glad to learn that the work, hitherto available only in one volume, will in future be obtainable in three separate parts dealing respectively with Specific Gravity, Separation and Determination of Minerals, and Detrital Sediments; Thin Sections; and Chemical Analyses and their Interpretation. The publishers are Messrs. Thomas Murby and Co., 1 Fleet Lane, E.C.4.

MESSRS. H. K. LEWIS AND CO., LTD., 28 Gower Place, London, W.C.1, are now issuing monthly lists of additions to their scientific and technical circulating library, instead of quarterly lists as previously. Every effort is made to meet the needs of workers in laboratories connected with the manufacturing industries, and the latest works on scientific research on all kinds of raw material and manufacturing processes are freely added to the library. These may also be seen in the technical books department, or a list will be sent to any inquirer.

WITH the assistance of prominent specialists in many parts of the world, Mr. Jerome Alexander, 50 East 41st Street, New York City, is preparing a comprehensive book on "Colloid Chemistry: Theoretical and Applied." British contributors include Dr. E. F. Armstrong, Prof. H. Bassett, Sir W. M. Bayliss, Dr. E. F. Burton, Mr. W. B. Hardy, Prof. F. G. Donnan, Mr. F. E. Lloyd, and Dr. A. E. Dunstan. Mr. Alexander invites any one who may have information of interest on experimental facts and practical applications of colloid chemical principles to send him a brief statement for inclusion in the book.

MESSRS. LONGMANS AND CO. have in the press "Friction," by Dr. T. E. Stanton, of the National Physical Laboratory, in which work the attempt is made to deal concisely with the whole subject of the mechanical friction which exists between bodies in contact, solid, liquid, or gaseous, under forces producing, or tending to produce, their relative motion. Attention is given to friction due to the flow of fluids over solid surfaces, with special reference to the dimensional theory; also to the lubrication theories of Osborne Reynolds, Michell, and Sommerfeld, and to the recent researches at the National Physical Laboratory on lubrication. The section on solid friction includes the theories of rolling friction and of the stability of structures on soft earth, together with the results of some modern experiments on materials used for brake blocks, and the final chapter is devoted to a discussion of Reynolds's theory of the relation between the heat transmitted to solid surfaces by fluids flowing over them and the frictional resistance of the surfaces due to the flow, and an examination of the experimental data bearing on this theory.

THE spring announcement list of Messrs. Chapman and Hall, Ltd., contains many books of scientific interest, among which are: "Vital Factors of Foods: Vitamins and Nutrition," by C. Ellis and Dr. Annie Louise Macleod, aiming at furnishing all essential facts regarding vitamins, and at bringing together the literature on the subject; "Perfumes and Cosmetics: with Special Reference to Synthetics," by W. A. Poucher; and "Electric Lift Equipment for Modern Buildings," by R. Grierson, which deals with the selection, installation, operation, and maintenance of modern electric passenger, goods, and service lifts. The same publishers will also issue a new and completely revised edition of "Electrical Engineering Practice," by J. W. Meares and R. E. Neale, in two volumes, the first of which will be ready shortly.

Research Items.

THE PYRAMIDS OF MEROE AND THE CANDACES OF ETHIOPIA.—A new chapter in the history of Egypt has been disclosed by the work of the Harvard-Boston Expedition in the Sudan, of which a summary is given by Prof. G. A. Reisner in *Sudan Notes and Records*, vol. v. No. 4. About 900 B.C. a Libyan family occupied Napata and seized the roads from Egypt to the mines and the southern markets. Ethiopia was then a province of Egypt, and for the first time they made it an independent kingdom and Egypt one of its provinces. They were not negroes, but of a mixed brown race which had previously lived in Ethiopia. For about 80 years they ruled 3000 miles of the Nile valley, and they were finally driven back to Ethiopia, ruling at Napata and building their pyramids there. In the end the branch settled at Meroe became the more powerful, and this kingdom persisted uninterrupted for another 650 years. Thus it has fallen to the lot of the expedition to trace the history of this family through more than twelve centuries.

HEAD-HUNTING IN PAPUA.—In the March issue of *Man* Mr. E. B. Riley gives an account of the method of preparing the heads of enemies practised at the village of Dorro in Papua. After the flesh and brains are removed a piece of rattan cane is fixed to the bottom of the mummified skull to take the place of the lower jaw and to act as a support for the packing of the neck. It was difficult to ascertain why the lower jaw is not replaced. The explanation seems to be that they prefer to hang this up in the house, and keep it as a mark or token of the owner's prowess in war, when the mummified head is discarded on account of natural decay; but the lower jaw is sometimes replaced, being tied to the zygomas, as in the case of the rattan cane above described. Finally, the head is dried, being fixed on a wooden framework over a fire lighted for that purpose, and the hair is pulled out on the second day as decomposition of the skin advances. Following this paper is a description by Dr. A. C. Haddon of stuffed human skulls from the Fly River District, Papua, two of which are preserved in the Cambridge and Manchester Museums.

CRIMINAL TRIBES OF INDIA.—The problem of dealing with the nomadic, predatory tribes of India has been considered for many years by the Imperial Government. All sorts of repressive measures have been put in force; the tribes have been proclaimed and attempts have been made to segregate them in settlements under police control. This system has always broken down, and these people, including the Sansias of the Punjab, the Doms of the United Provinces and Bihar, the Yerukalas and Korachas of Madras, have continued to be a pest to the country, and much violent crime was committed by them. Some twenty years ago a proposal was made by the Salvation Army to take charge of these people, and the result of the experiment is described in a paper by Commissioner Booth Tucker, read before the Royal Society of Arts (vol. lxxi. No. 3661). The Salvation Army has collected some of these people in settlements, each in charge of a European, where the more respectable members act as police, industries are taught, and efforts made to raise their moral character. In the debate which followed the reading of this paper several experienced Indian administrators, including Sir E. A. Henry, Sir John Hewitt, and Lord Pentland, bore testimony to the success of the experiment, which may be said to have solved one of the most difficult problems of Indian administration.

FATIGUE IN LAUNDRY WORK.—Miss May Smith is to be congratulated upon her recent Report (No. 22) to the Industrial Fatigue Research Board (H.M. Stationery Office, price 2*s.* 6*d.*), embodying "Some Studies in the Laundry Trade." Owing to the great variety of articles dealt with in laundries, the measurement of output, so as to serve as an index of the relations between working conditions and the human factor, proved unusually difficult. Nevertheless, she has been able to show that there is a reduction in efficiency in laundries towards the end of the day, which tends to be greater during a ten-hour than during a nine-hour day. These conclusions are strikingly corroborated by the data afforded by the interposition of "dotting" tests, which, in addition, reflect passing variations in the health and mental state of the worker. Miss Smith finds clear evidence of the beneficial effects on efficiency which occur after a fifteen minutes' rest pause has been introduced into the morning spell, but the greatest influence on the laundresses' output appears to be due to the vast individual differences in the workers' efficiency. Apparently the atmospheric conditions of laundries compare very unfavourably with those in potters' shops, boot and shoe factories, and cotton-weaving sheds. But when conducted under good conditions, Miss Smith believes that laundry work is not detrimental to the health of the workers. The variations in health due to excessive standing, faulty movements, and improperly designed machinery receive attention, and recommendations are made in regard to supervisors, the provision of seating, unsuitable footwear, change of occupation, etc.

OUR OLDEST SETTLEMENT IN AFRICA.—Dr. Frank Dixey has followed up his physiographic description of the colony of Sierra Leone (see NATURE, vol. 105, p. 689, 1920) by a complete petrographic survey of the main promontory (Quart. Journ. Geol. Soc. London, vol. 78, p. 299, December 1922). The peninsula forming the colony proper has been carved out of a remarkably uniform and unusually large stock of norite, the fine-grained character of which indicates that the present surface follows that of a dome of intrusion. Veins of coarser norite, and some of aplite, cut this mass, which is regarded as post-Cambrian, but of ancient date. The only strata on its surface are post-Pliocene gravels. This extensive occurrence of basic igneous rock furnishes further evidence of the existence of a West African petrographic province of strongly magnesian character.

SURVEYS OF THE SAHARA.—A new map of the western Sahara, between the Atlas to the north, and the Senegal and Niger to the south, and the meridian of Paris on the east, is published in *La Geographie* for January. The map, which is on a scale of 1 : 2,000,000 is based on information collected by the French military posts in the Algerian Sahara, Mauretania, and the Sudan, and particularly the explorations of Capt. Augiéras who, in addition to various journeys in the Sahara between 1913 and 1917, crossed the desert with a small column in 1919–20 from Algeria to Senegal. This crossing, which is briefly described in an article accompanying the map, was from the French outpost of Tabelbala, south of Colomb Bechar, in a south-westerly direction to the outpost of Atar, whence by a circuitous route Bogue on the Senegal was reached. This entailed, from post to post, a total march by camel of some 1500 miles, which was accomplished, excluding rests, in 78 days. In such a survey there must obviously be inaccuracies and Capt. Augiéras regrets his inability to get more satisfactory longitudes, but the

map shows great improvements on former maps of this part of the Sahara.

DISTRIBUTION OF ICE IN ARCTIC SEAS.—The publication by the Danish Meteorological Institute of "The State of the Ice in the Arctic Seas, 1922," directs attention to a somewhat unusual year, but unfortunately information is almost entirely lacking from Siberian waters and very scanty from the Beaufort Sea. By April the extent of pack in the Barents Sea was much smaller than usual. Bear Island, which had been free from ice all winter, was clear and open water almost reached to Novaya Zemlya. The edge of the ice continued to retreat. In July the whole west coast of Novaya Zemlya was clear, and in August Franz Josef Land was probably accessible by open sea. Early in the year conditions in Spitsbergen were about normal. In May and early June an unusual amount of ice drove round the South Cape before continuous easterly winds, but this resulted in the west coast being practically free from ice for the remainder of the summer. On the north coast conditions were particularly favourable, and a vessel reached lat. 81° 29′ N. Some sealers circumnavigated Spitsbergen, a feat that is not possible in most years. In the Greenland Sea the belt of pack lay more westerly than usual, and though the east coast of Greenland does not appear to have been clear of ice, open water touched the coast in about lat. 74° N. during August. Jan Mayen and the coast of Iceland were free from pack from May onwards throughout the summer. On the Newfoundland banks both pack and icebergs were abundant in early spring, but July was clearer than usual. In Davis Strait the winter ice was thinner and the "west ice" less abundant than usual. In Bering Strait conditions were fairly normal, but along the north coast of Alaska the pack pressed hard and navigation was much hindered.

EARLY HISTORY OF THE BLACK CURRANT.—The *Gardeners' Chronicle* has recently commenced a very interesting series of notes under the heading "Early Botanic Painters." In the issue of February 17, the figures of the Black Currant reproduced from the paintings by Jean Bourdichon (1457–? 1521) are extremely interesting, and raise the query whether the cultivation of the black currant may not be of longer date than is usually supposed. R. G. Halton of the East Malling Research Station has recently described existing varieties of the Black Currant, and to judge from his brief account of its early history (*Journal of Pomology*, vol i. No. 2, p. 68), it receives scant notice from the earlier chroniclers of horticultural effort.

A NEW CULTURE MEDIUM FOR BACTERIAL COUNT WORK.—For bacterial counting work, in which the plating method is used, a first essential of accuracy is that the medium used in plating should give uniform results. There are two respects in which a medium should display this uniformity. In the first place, it should be reproducible, that is to say, different batches of medium should give similar results. In a medium recently developed at Rothamsted (H. G. Thornton, *Annals of Applied Biology*, vol. ix. p. 241, 1923), this reproducibility has been achieved by using pure chemical compounds as food constituents and especially by selecting those compounds that were found not to alter the reaction of the medium during sterilisation. In the second place, parallel platings of a suspension of organisms made on a *single* batch of medium should develop the same number of colonies (within the limits of random sampling variance). Uniformity in this respect involves the independent development of each colony on the plate, and on agar media this is frequently prevented by the development of bacteria that form rapidly spreading colonies which interfere with the development of other bacteria. A special study was therefore made of a common "spreading" organism with a view of limiting its growth. It was found that the organism spread over the agar surface by active motility and that the factors controlling its spread were (1) the existence of a surface film of water on the agar, and (2) the rate of multiplication previous to the drying of this film. In the present medium this rate of multiplication has been much reduced, so that spreading colonies are greatly restricted.

SILKWORM DISEASES IN INDIA.—The subject of silkworm diseases is not a new one in India, but notwithstanding the fact that sericulture is probably a much older industry in that country than in Europe, there are no corresponding early records of disease, The whole problem is very fully discussed in a recent memoir by Dr. A. Pringle Jameson (Report on the Diseases of Silkworms in India, Calcutta, 1922. pp. 165 and 8 plates). It appears that all the recognised diseases are prevalent, and those of the mulberry, muga, and eri worms are the same. Pebrine is only of importance in mulberry worms: losses are still heavy, mainly because the majority of rearers use unexamined eggs or "seed." Muscardine is almost confined to mulberry worms and is a most serious complaint, whole rearings being frequently lost. Flacherie is of less importance in mulberry worms, while grasserie is stated to cause loss to all species. Conditions in India make the control of disease considerably more difficult than in temperate countries, but there is no reason why the industry should not be placed upon a surer footing. The crux of the whole question lies in the "ryot," and, if improvement is to be effected, the village rearer must be instructed as to the causes of disease and induced to go in for better methods of rearing. Since the industry is carried on by cottagers, the latter should be encouraged to use disease-free "seed." The extension of the Government nursery policy will avail little unless the rearer can be induced to educate himself to adopt better methods. The most important work of the Government sericultural officers should be instruction and supervision, while sericultural schools should be established. The sericultural department officials themselves should conduct research work on a practical scale, and an attempt should be made to provide them with the chief literature on this subject in order that they may keep abreast with sericultural research. Improvements are to be looked for from the work of the provincial sericultural departments being extended among the villages.

FIBRES FROM THE TROPICS.—A noticeable feature of journals recording activities in tropical agriculture is the interest at present being taken in the subject of fibre production. The *Tropical Agriculturalist*, issued from Peradeniya, records promising experiments with cotton, and in its December issue (1922) devotes considerable space to a paper by E. Mathieu, superintendent of the Government Plantation, Kuala Kangsar, upon the cultivation of the "Kapok" tree, *Eriodendron Anfractuosum*. In the fruits of this plant, hairs grow freely on the inner side of the valves of the capsule but not upon the seeds themselves, so that the separation of the fibre from the seed is a relatively easy matter. The export of this fibre from Java in 1912 exceeded 10,000 tons, and owing to the increasing demand from Europe and America, its cultivation seems likely to extend in Ceylon.

The same number of this journal has a note by A. P. Waldock upon the "akund" fibre, obtained from the shrubs *Calatropis gigantea* and *C. procera*, which the writer considers may have industrial possibilities as a village industry. In *Industrial India*, vol. i. No. 12, the possibilities are discussed of the "roselle" fibre, obtained from the bark of *Hibiscus Sadariffa*, particularly var. *Altissima*, which is said to have given good yields of fibre in Malaya, in regions with rainfall between 90 and 120 inches. For dry tropical regions there is "sisal," the fibre from the leaf of *Agave rigida*, var. *sisalana*. In *Tropical Life* for January Major L. A. Notcutt begins an interesting discussion of the possibilities of the cultivation and extraction of sisal, more particularly with reference to the problem whether the East African product may hope to compete with the Mexican in cost of production. At present our knowledge with all these fibre plants as to what conditions in cultivation favour maximum fibre development in the plant is entirely empirical, but such recent researches as those of Dr. W. L. Balls and H. A. Hancock (Proc. Roy. Soc., 93 B, 426-439, 1922) upon the growth of the cotton hair, and the numerous investigations upon cotton and flax, now being published in the Journal of the Textile Institute, arouse hopes that we may soon have a deeper insight into the problem of wall formation and thickening in the plant, and this should prove the first step towards the control of cultivation with the view of facilitating the formation of fibre.

Foraminiferal Sands in Corsica.—Messrs. E. Heron-Allen and A. Earland (Bull. Soc. Sci. hist. et nat. de la Corse, 1922, p. 100, Bastia) find that the red sands of the Gulf of Ajaccio, which were supposed to owe their colour to derivation from adjacent granite rocks, are in reality largely composed of foraminifera. Some ten per cent. of their volume is composed of the rose-pink *Polytrema miniaceum*, a species having a wide distribution in the Mediterranean, with which Mr. Heron-Allen was concerned in his recent report for the *Terra Nova* expedition. The authors, in an inserted fly-sheet, show that they have much cause to complain (as was remarked in the famous "Printers' Bible") that printers have persecuted them without cause.

Deposition of Silica in Sedimentary Rocks.—In such cases as the famous Devonian cherts of Rhynie, or the silicified forest of Arizona, geologists have urged the probability of an invasion of silica in solution from volcanic magmas. In suitable climatic conditions, however, much silica must be set free during laterising processes, and this may wander far from its original source. In the Proceedings of the Rhodesia Scientific Association, vol. 20, p. 9, 1922, Mr. H. B. Manfe records the interesting case of the silicification of a fairly recent freshwater shale at the base of the Kalahari Sands at Gwampa. Mr. T. B. Lawler of Princeton University (*Amer. Journ. Sci.*, vol. 205, p. 160, 1923) describes the sheets of chalcetory that traverse the Oligocene strata of S. Dakota, passing alike through the sands and the included fossils. He attributes the vertical cracks in which they have been deposited to the squeezing out of water during the settling down of the beds, as the humid conditions of Oligocene times in the Dakota area were succeeded by an arid climate in the Miocene period.

Earthquake Periodicity and Tidal Stresses.—Recent numbers of the Bulletin of the Seismological Society of America (vol. 12, 1922, pp. 49-198) contain a memoir by Mr. Leo A. Cotton on earthquake periodicity with special reference to tidal stresses in the lithosphere. A welcome feature is the sympathetic examination of Perrey's neglected laws (of greater frequency about the syzygies, perigee, and the lunar passages of the meridian); the author considers that the first and second are supported by a high degree of probability, while the third is unsound. The second part of the memoir deals with the effects of tidal stresses in the earth's crust, with special reference to the geological aspects of the subject, such as the position of the originating faults. The author considers 316 world-shaking earthquakes from 1899 to 1903, and shows that earthquakes are more frequent when the sun or moon is near the horizon, and that there is a very high maximum of frequency when the sun and moon are so situated that they exert their tidal stresses in the same direction.

Meteorology at Liverpool.—Results deduced from the meteorological observations taken at the Liverpool Observatory, Bidston, in the years 1920 and 1921, have recently been published by the Mersey Docks and Harbour Board. The report and discussion was prepared by Mr. W. E. Plummer, director of the observatory. Observations are supplied three times daily to the Meteorological Office, which also receives monthly and annual returns. Daily results are given for the two years and the total and means are grouped for each month and each year. For 1920 the mean atmospheric pressure was 29·942 in. (printed in error as 29·924 in.); the mean was above 30 in. in 5 months. The mean air temperature was 49·6° F., which is 0·5° F. above the normal, the absolute maximum was 78° F. and the minimum 21° F. The total rainfall was 33·34 in., which is 4·82 in. more than the normal; the duration of sunshine was 1257 hours, which is 222 hours less than the normal. For 1921 the mean barometric pressure was 30·045 in., which is more than a tenth of an inch higher than in 1920; in a similar report for Southport especial mention was made of the exceptionally high barometric pressure which characterised 1921. The mean at Liverpool was above 30 in. in 7 months. The mean air temperature was 51° F., which is 1·9° F. above the normal; the absolute maximum was 86° F. and the minimum 28° F. The total rainfall was 22·47 in., which is 5·95 in. less than the normal; the duration of sunshine was 1585 hours, which is 99 hours more than the normal. The general modification of scales for the several elements which is being uniformly adopted by the Meteorological Office is not as yet being followed at the Liverpool Observatory.

The Scattering of Light by Liquids.—When a beam of ordinary light passes through a liquid its intensity gradually diminishes according to the exponential law owing to the scattering of the light by the molecules of the liquid. The light scattered in a direction transverse to the beam should be completely polarised. According to a paper in the March issue of the *Philosophical Magazine*, Prof. C. V. Raman and Mr. Rao have examined nine liquids to determine to what extent the theories of scattering are in agreement with the facts, and find that the Einstein-Smoluchowski theory is the most satisfactory. According to it the scattering should be proportional to the compressibility and absolute temperature of the liquid and inversely proportional to the fourth power of the wave-length of the light used. They find that the transverse light is only partially polarised, but, on applying the correction specified by Cabannes, which is due to the non-symmetrical molecules, the theory gives correctly the amount of the scattering. As the critical temperature of the liquid is approached, the scattering becomes very large and the polarisation of the scattered light more complete.

The Indian Science Congress.

THERE is a real danger that the severe retrenchment in public expenditure now in progress in India may lead to a curtailment of activities in those departments in which such restriction is least desirable, namely, the educational and scientific services devoted respectively to the training of workers and the investigation and development of the resources of the country. It was therefore very opportune that the presidential address delivered at the Indian Science Congress which has completed its tenth session at Lucknow (January 8-13) emphasised the danger of apathy towards scientific knowledge and the immense problems bearing upon the welfare of India still awaiting solution. The president, Sir M. Visvesvaraya, himself a distinguished engineer and for many years the successful administrator of one of the largest and most progressive of the Indian States, rightly laid stress on the appalling state of destitution in which quite 100 million out of the total population of 320 million in the country live, and the necessity for scientific research to increase the food supply, raise the standard of living, develop resources and train the people for citizenship. The address contained constructive suggestions towards stimulating research, promoting co-operation and concentration of effort and making the results of scientific work both in India and abroad more readily available.

The sectional presidents dealt with a variety of subjects and their addresses were mostly of a general character. A few words regarding each must suffice, and those who are interested will no doubt refer to the complete report which will before long be published by the Asiatic Society of Bengal. In his discourse to the Section of Physics and Mathematics, Dr. S. K. Banerji reviewed recent theories regarding the origin of cyclones and discussed in particular the cyclones of the Indian seas, their origin, movements and disappearance. He favoured the view that counter currents having their origin in differences in temperatures over large geographic areas initiate the conditions that give rise to a system of gyrating winds in these storms, and that the condensation of water vapour supplies the energy necessary to maintain them for a long period of time. Dr. Meldrum in a brief opening address to the Section of Chemistry made out a case for regarding the study of this subject as a liberalising influence.

Mrs. Howard in her address to the Botanical Section dealt with the rôle of plant physiology in agriculture and indicated a number of directions in which botanical research is desirable, such as the factors underlying high quality in agricultural produce, the scientific interpretation of field experiments, the precise nature of various agricultural practices which come under the head of mutilations, the relations between physiology and the incidence of disease, and the basis of acclimatisation and change of seed. It was suggested that investigators in the Indian universities would find in these subjects many problems of great scientific interest and practical importance.

Dr. Pillai in his address to the Section of Agriculture epitomised recent researches in soil science. Prof. G. Matthai gave the Section of Zoology a very interesting survey of recent oceanographical research, with special reference to the Indian Ocean, dealing very fully with the physical and chemical factors influencing marine life and its distribution. Especially noteworthy was the reference to recent work on the colour of the light that penetrates by transmission and scattering into the depths of clear ocean water and its possible influence on the coloration of marine fauna and the development of their powers of vision. In the Section of Geology, Dr. Pascoe dealt with the palæography of Burma. Major Acton discoursed on the aims and economic value of medical research to the section devoted to this subject. The importance and interest attaching to the study of cultural anthropology was well emphasised by Dr. J. J. Modi in the section over which he presided.

A general survey of the work of the Congress indicates that scientific investigations in India are to a considerable extent directed by the special needs of the country, and indeed perhaps even more attention should be given than at present to subjects such as the chemistry of Indian natural products and problems arising therefrom. As an example of the kind of work being accomplished at present in this direction may be mentioned an interesting paper by J. L. Simonsen and M. Gopala Rao in which they showed that an exceedingly small proportion of pyrogallol added to Indian turpentine inhibits its tendency to oxidation for some months and thus adds greatly to its value. The practical side of research was also emphasised in a symposium of the Sections of Agriculture, Botany and Chemistry, in which a whole morning was devoted to the discussion of the nitrogen problem in Indian agriculture, and in another joint meeting, of the Sections of Botany and Agriculture, devoted to the improvement of fodder and forage in India. The same tendency is also found strongly reflected in the proceedings of some of the sections, notably in those just mentioned and in the Section of Medical Research.

Fundamental research as distinguished from applied science was strongly represented in the physics section of the Congress, and this was largely owing to the influence of the Calcutta school which has grown up during the past few years. Among some of the papers which dealt with new fields of research may be mentioned one by Mr. K. Seshagiri Rao on the scattering of light in fluids at low temperatures. A remarkable fact elicited by recent work (see Proc. Roy. Soc., November 1922, p. 159) is that the light transversely scattered in liquids which at ordinary temperatures is very imperfectly polarised increases in intensity and at the same time becomes more and more completely polarised as the temperature is raised towards the critical point. In Mr. Seshagiri Rao's work, the study of the scattering is carried down to low temperatures, and an effect of the opposite kind is noticed. The quantitative results promise to throw light on the nature and magnitude of the thermal agitation of the molecules at low temperatures. An analogous investigation by Mr. Lalji Srivastava on the scattering of light in crystals was also presented to the Congress.

There is scarcely space to refer here in detail to the numerous other papers dealing with subjects so varied as vortex motion in fluids, formation of ripple-marks, earthquake coda, chromatic emulsions, acoustics of the pianoforte, whispering galleries, theory of band-spectra, temperature ionisation of gases, and α-ray tracks in argon and helium, to mention only a selection, presented to the section at Lucknow. A reference may, however, be made to a paper which evoked a most animated discussion at the meeting, that is one by the writer putting forward a new theory of the well-known blue colour of clear ice in glaciers (see NATURE, January 6). In reply to some of the points raised, attention was directed to the very remarkable fact that during the process of artificial crystallisation involved in the manufacture of ice, the suspended matter originally present in the water is rejected by the crystals as they form and accumulates in a pocket. Ice which shows the blue opalescence is quite free from colloidal matter of any kind.

C. V. RAMAN.

The Exploitation of the Sea.

TWO very important documents bearing on the subject of the rational exploitation of fishing grounds have recently become available. The first is the report to the Minister of Agriculture and Fisheries of the British delegates who attended the meeting of the International Council for the Exploration of the Sea, held at Copenhagen in September last. The other is the Report of the Danish Biological Station (xxix., 1922). Both papers are of very great interest.

The British official report emphasises the practical nature of the work of the Council and gives an account of its organisation. There are four sections (hydrography, plankton, statistics, and fish). The work of the fish section is carried out by committees, and those which deal with the investigation of the herring, cod and haddock, and of the biology of the Atlantic slope are of great interest to British workers. Programmes of the investigations adopted by these committees are given in the report. One important committee, that on the plaice fisheries, has now completed its work, and the recommendations made by it have been approved by the Council and are given in full. These are that the parts of the North Sea situated (1) between the Continental coast and the 12-fathom line from N. lats. 52° to 56°, and (2) between the 12-fathom and the 15-fathom line, be closed to steam trawlers and motor vessels of more than 50 h.p., the inner zone throughout the entire year and the outer one during the months July to March. No size-limits with respect to the fish caught are recommended. The Council recognises the difficulty of enforcing these measures without the sympathetic support of the fishing industry, but it regards this as a matter for the concern of the governments of the participating countries. It is considered that the adhesion of Germany to such a scheme of regulation will be essential. The Council advises the continuance of observations and the review of the whole proceedings after three years have elapsed.

The meaning of the impoverishment of a plaice fishing ground is examined by Dr. C. G. J. Petersen in the second of the reports noticed. Since 1893 this distinguished Danish zoologist has studied the fisheries in the Limfiord and in the adjacent seas. In 1893 the old styles of plaice fishing were superseded by newer and more efficient methods, and Dr. Petersen thought then that this meant "the end of the golden day for the fishing industry," and he had similar thoughts about the North Sea plaice fisheries. Now he confesses that later developments have shown that he was wrong. What has occurred in the two areas is much the same; the quantities of plaice taken per day's fishing by the old types of vessels were much greater than those now being taken by the newer boats fitted with much more efficient gear. Why? In both areas there was an "accumulated stock" of fish. Vessels of low fishing capacity could do well on such grounds.

How to remedy this "impoverishment"? There are two theories of regulation: (1) to raise more young plaice either by protecting the breeding fish so as to allow them to reproduce at least once in their lifetimes, or by artificial hatching, and (2) to legislate and otherwise deal with the fishery so as to increase the *growth-rate* of the plaice, because it is not merely a vast quantity of fish on the grounds that is desirable but rather an increased rate of production of plaice-flesh. An overcrowded ground may harbour small old plaice or young and relatively big ones. Plaice which do not grow at all consume from three to four times their own weight of food. In the Baltic there are fish of 32-36 cm. in length which are 4-5 years old as well as others of the same sizes but of 9-18 years old. The best policy is so to regulate the fishing as to increase the proportion of the younger, more rapidly-growing fish.

How to do this? The conditions in the North Sea illustrate the difficulty—and the remedy. If the Dogger Bank were an island surrounded by shallow water, vastly more plaice would grow to good marketable sizes than do now. As it is, the fishing is probably too intense and plaice are caught more rapidly than they can migrate out from the overcrowded grounds just off the Continental coasts. The restocking of the deeper parts, where the fish will grow well, from the nurseries (where they grow slowly) must keep pace with the depletion of these grounds. This means two kinds of measures: (1) size-limits in fishing, and (2) transplantation, both being modified according to the circumstances. If young plaice do not migrate out into favourable parts of the North Sea they must be assisted. Dr. Petersen himself made successful transplantation experiments in the Limfiord long ago, and more recently, English investigators have shown, beyond all doubt, that the same measures were practicable, and sure to be highly successful, in the North Sea.

The rationale of a continued and still more intensive exploitation of the fishing grounds is indicated by the scientific investigations. The transplantation experiments show which are the favourable grounds; growth-rates are known, and the work now in progress by the English investigators is giving results of value in regard to the supplies of food on the various grounds. The difficulties belong only to the practical working of the regulatory measures. Something like a scientific "nationalisation" of the deep-sea fishing industry appears to be necessary in the interest of an increased food supply, should the apprehensions of a failing stock be justified. It seems like a revolutionary proposal to suggest that permission to exploit the offshore fishing grounds should become necessary and that this permission should be accompanied by certain conditions, yet something of the kind may have to come in the near future. Meanwhile the scientific work in progress is affording the data whereby such proposals can materialise when the administrations are ready. J. J.

Solar Radiation.

VOLUME IV. of the Annals of the Astrophysical Observatory of the Smithsonian Institution contains the investigations on solar radiation made by the director, Prof. C. G. Abbot, assisted by F. E. Fowle, L. B. Aldrich, and others. The work in the Northern Hemisphere has been transferred from Mt. Wilson to Mt. Harqua Hala, Arizona; that in Chile from Calama to Mt. Montezuma. In 1914 pyrheliometers were taken up to a height of 25 km. by small balloons. The atmospheric pressure was 3 cm. of mercury; the value of the solar constant indicated was 1·84 calories per cm.^{2}, in good agreement with the adopted value.

Mr. Clayton compared the variations of solar radiation measured in 1913–14 with the temperature records in various parts of the world; he found a

correlation that was positive in the Tropics and Polar regions, negative in the Temperate zones. He also found that the temperature in Argentina was correlated to the short-period variations of radiation observed in Chile, and he suggests that these changes have a tendency to recur in periods of 12 and 22 days. They are interpreted as being due to varying transparency of the solar atmosphere. Measures of the brightness of Saturn indicated similar variations, but with a time-interval proportional to the difference of longitude of Saturn and earth. This would be explained by the solar regions of high or low radiation being carried round by the sun's rotation.

The excess of radiation at sunspot maximum is explained by the greater activity of solar convection currents at that time; these bring hot matter from the interior to the surface, which more than balances the loss of heat in the spots themselves.

The mean state of transparency of the solar atmosphere is measured by observations of the radiation at different distances from the centre of the disc. The contrast between centre and limbs is found to be greatest when the solar spot activity is greatest. On the other hand, the short-period increases of radiation are associated with less contrast between centre and limb.

The work also gives information on the transparency to radiation of different layers of our own atmosphere. "The atmosphere above 11 km. contributes more than half the radiation of the earth viewed as a planet. . . . Nearly the entire output of radiation of the earth to space, more than ¾, arises from the atmosphere and clouds."

The albedo of a large white cloud in the sunshine was measured from a balloon above it and found to be 78 per cent. Prof. H. N. Russell's discussion of Müller's observations of the albedo of Venus gave the value 59 per cent. It is concluded that the clouds on Venus while general are not thick enough to give full cloud reflection except for oblique rays. The albedo of the earth seen from space is estimated as between 43 and 45 per cent.

Botulism in Scotland.

THE Scottish Board of Health has issued a very clear and interesting report on the circumstances attending the deaths of eight persons from botulism at Loch Maree in Ross-shire last year, and none of the vivid tragedy of the occurrence is lost in the telling by Dr. G. R. Leighton.

On August 14, 1922, a number of guests stopping in the hotel went out for the day, and within a week six of them, as well as two of the attendant ghillies, were dead. Once some sort of food poisoning was suspected, the distribution of the fatalities between these living in the hotel and those living in their own homes in the neighbourhood at once implicated luncheon, the only meal taken in common, as the source of the poison, and further inquiries appeared to bring particular suspicion on a glass jar of wild-duck paste out of which about a dozen of the sandwiches had been made. The empty jar was fortunately recovered, and Mr. Bruce White, at the University of Bristol, was able to show that the small fragments of paste left in it were intensely poisonous to mice, and from them to isolate the *Bacillus botulinus* itself. One of the ghillies was not hungry enough to eat all his sandwiches and took one home with him; when he fell ill next day and rumour suggested something wrong with the lunch his friends buried the sandwich, which was retrieved later and shown by animal experiment to be extremely toxic. A guest also failed in his appetite and threw the most part of a sandwich to a wagtail on the lake shore; a month later Dr. Leighton found the decayed remains of a small bird among the stones.

There has, indeed, seldom been an outbreak of food poisoning in which the facts were so clear and so plainly verified. The only point of interest which the report fails to elucidate—and perhaps the facts could not be ascertained with complete accuracy—is how many people ate any of the poisonous paste without having symptoms: it seems likely that there may have been about five.

As has lately been shown by Dr. K. F. Meyer of the University of California (NATURE, January 20, p. 95) *B. botulinus* is a widespread common inhabitant of the soil, and may often be found on fruits, vegetables, and other food-stuffs. Taken with food in any numbers that are reasonably possible it is harmless, and in this way differs sharply from the food poisoning bacilli of the Gaertner and Aertrycke group, which multiply inside the body and cause illness by producing a definite infection. *B. botulinus* is poisonous only if it has been able to grow for some time under favourable conditions outside the body and produce large quantities of its potent toxin; man is poisoned by the toxin, not infected by the bacillus. Laboratory experiments show that the resting spores are exceptionally difficult to kill by heating. Considering, indeed, the wide distribution of the bacillus in Nature, the rarity of botulism is a remarkable testimony to the care with which potted meats and so on are usually prepared. Really efficient sterilisation is a secure preventive. The difficulty is that the glass containers, which the public æsthetically prefers, cannot be heated to a sufficiently high temperature without an undue proportion of breakages. There seems to be no good reason why they should not be prohibited and tins made compulsory.

Building Construction Research.

THREE reports on investigations connected with house construction and allied subjects have recently been issued by the Department of Scientific and Industrial Research.[1]

In the first of these, Mr. W. H. Wainwright gives some details of the cost of cottage building, and at the present time, when the cost of building is a very vexed subject and development schemes have to be very carefully debated owing to financial stringency, such information should be valuable. It is only by careful analysis in the matter of outlay that organisation can be improved and economy effected, and those engaged in large building works will find in these tables much interesting matter. The diagrams are partly compiled from data collected by the Ministry of Health; some are calculating graphics which should save time and do something to popularise graphic methods among technicians, while others show the rise and fall of prices in labour and materials from 1914 to 1922 and are of general application.

Mr. Weller in his editorial introduction anticipates

[1] Department of Scientific and Industrial Research. Building Research Board: Special Report No. 6, "A Graphical Cost Analysis of Cottage-Building." By W. H. Wainwright. Pp. iv+8+20 diagrams. 2s. 6d. net. Building Research Board: Special Report No. 5, "Building in Cob and Pisé de Terre: a Collection of Notes from Various Sources on the Construction of Earth Walls." Pp. iv+40. 2s. net. Fuel Research Board: Special Report No. 4, "Tests on Ranges and Cooking Appliances." By A. H. Barker. An Extract from the Report of the Building Materials Research Committee. Pp. vi+55+15 figs. 2s. 6d. net. (London: H. M. Stationery Office, 1922.)

an obvious criticism that the basis of calculation may be of changing value owing to changed conditions by stating that the percentage cost of materials in a cottage in 1914 and 1921 was found practically identical. From the diagrams the increased cost of a cottage due to variation in the market price of a material can be at once ascertained. We imagine that variations in human output are a good deal less amenable to graphic representation. Apart from this, however, a great deal of useful matter on relative costs and methods of calculation will remain truly recorded in this publication.

The notes which constitute the report on cob and *pisé* building form an interesting epitome of a subject which came into great prominence during and after the war, when bricks were prohibitive in price and the bricklayer was laying them at a minimum rate never contemplated. It is very unlikely that the methods of building described will ever become general, though in special local circumstances they will continue to have value.

The contributors to these notes write quite dispassionately, a fact which adds greatly to the value of the concise information given. Various methods used are explained in detail with dimensioned sketches of the simple shuttering and tools used in this construction, while photographs of cob and *pisé* cottages show how satisfactory a home it is possible to produce, even for two-storied buildings, direct from natural earths. Walls, which may be of lumps from a mould or formed *in situ*, are one or two feet in thickness and the houses are said to enjoy a very equable temperature and to remain dry, but a brick or concrete foundation about a foot high is necessary. The recent times of stress have produced a great many new types of building, but if we are to judge from American experience it would seem that, taking capital and current cost over a decade, the ordinary brick still holds its own against later competitors.

Houses or cottages having been constructed, it is necessary to provide heating appliances, and range-makers and others will find much useful information in the third of these reports. The necessity for the conservation of fuel energy during the war provided the stimulus for this useful investigation. It is common knowledge that the kitchen range is, in most houses, the main and most wasteful coal consumer, and it is surprising that range-makers have not before now turned their attention to the production of more efficient designs. This may be due partly, as the author points out, to the incompatibility of running economy and initial low cost of apparatus, but if capital and current costs were simply tabulated the purchaser would soon realise the ultimate cheapness of a range designed to utilise more heat units.

The purposes of a range for boiling, baking, water heating, and perhaps warming, render, the report tells us, a really economical design impossible, and attention should therefore be directed to the consideration of any means for separating these functions which might be practicable at least in large establishments. These functions were tested independently both from a broad physical and also from a purely culinary standpoint. Considered as separate functions, only 2½ per cent. of the heat is transmitted to the oven, 12 per cent. to heating water, and 1·5 per cent. to the hot plate, as an average for commercial ranges. These figures were very largely increased in appliances designed during the tests. It has been stated that market conditions preclude the commercial success of many improved types of range.

Diseases of Plants in England in 1920–21.[1]

By Dr. E. J. BUTLER, C.I.E.

MOST countries in the civilised world have been forced within the last twenty years to take steps to protect their crops from the menace of foreign parasites. During that period, with the growing recognition of the aid that science can give to agriculture by studying the cause and control of plant diseases and pests, has come a great increase in knowledge of the dangers of unrestricted traffic in plants. Many instances have occurred to prove how real is the risk of introducing plant parasites from other countries and how difficult to guard against. America has been the chief sufferer, but it is sufficient to mention gooseberry mildew and wart diseases of potato to show that England has not escaped. Distances, as measured in time and in the amenities of transport, are constantly contracting between the continents, and the interchange of living plants—with their parasites—goes on in ever-increasing volume. Quarantine restrictions, at first imposed in a few special cases, have extended until at present the exporting seedsman or nurseryman is faced with barriers to his trade which are often extremely hampering. It is easier for a human being to enter the United States to-day than for a potato, unless it is accompanied by a sheaf of health certificates; while total prohibition of certain categories of plants is not uncommon.

Correspondingly heavy responsibilities have fallen on the official plant pathologists of the various countries. Produce for export has to be inspected and certified, and imports from each country have to be scrutinised for possible dangers. As an essential foundation for efficiency in what may be called the "Plant Protection Service," it is obviously necessary to know what diseases already exist in one's own country and what may be introduced from each of the countries from which imports are received. Plant disease surveys have been developed in nearly all the more advanced countries, that of the United States being the most complete, as is natural in view of the vast interests involved. So far as the fungous diseases are concerned, it is to Mr. A. D. Cotton, mycologist to the Ministry of Agriculture, that is due the organisation of the English survey. The present report is the third of the series for which he has been responsible, and will be the last in view of his appointment as keeper of the Herbarium, Royal Botanic Gardens, Kew. It is also by far the most complete that has yet appeared and is second to none in any European country.

The report covers the two years 1920 and 1921. These years offered an extreme contrast in their meteorological features, and not the least valuable of the results of the survey is the way in which the differences in the two seasons are reflected in the incidence of particular diseases. Potato blight, a lover of cool and damp conditions, was rampant in 1920, but could not withstand the hot, dry summer of 1921. The attack of crown rust on oats in Wales was unprecedented in the former year and singularly slight in 1921. The mildews, on the other hand, were unusually bad in 1921, and common scab of potatoes,

[1] Ministry of Agriculture and Fisheries. Report on the Occurrence of Fungus, Bacterial and Allied Diseases on Crops in England and Wales for the years 1920–21. (Miscellaneous Publications, No. 38.) Pp. 104. (London: H.M. Stationery Office, 1922.) 3s. net.

a disease that has recently been shown to prefer warm soils, established a record in virulence.

One may hope that the accumulation of such facts (of which the report contains many), and their correlation with the weather charts which are attached, will enable trustworthy forecasts of the intensity of particular diseases to be issued. It is unnecessary to emphasise the practical value of this to the grower.

Another point of the highest practical interest, and one that is best brought out by the methodical records of a survey, is that of varietal resistance to specific diseases. Such a year as 1920 is invaluable in establishing the behaviour of different varieties of potatoes to blight under optimum conditions for the latter. Kerr's Pink, for example, appears at or near the top of nearly all the lists of blight-resistant potatoes that are also immune to wart disease.

Equally valuable are the records of new crop parasites. No less than 136 names have been added to this report as compared with that for 1919, and several of these are diseases not previously known to occur in the country.

The report deserves a wide circulation at home and abroad, as it presents in a handy and convenient form a remarkably complete summary of the fungous and allied troubles with which the British grower has to contend.

Wave-power Transmission.

AN interesting paper has recently been presented to the North-East Coast Institution of Engineers and Shipbuilders, by W. Dinwiddie, on wave-power transmission. Wave-power machines are classified under three heads: (1) Continuous waves, where the generating plunger moves with simple harmonic motion. (2) Impulse waves, in which a single harmonic motion is transmitted in wave form at regular intervals, greater than the period of the motion itself. (3) Sychronous and asychronous motors, monophase or polyphase, in which direction research is proceeding.

Liquids such as oils and water are at present the media used, while the transmission of impulse along a steel wire has been used. A reciprocating pump plunger of small stroke is oscillated at a high speed at one end of a closed pipe line. Waves of compression and expansion are propagated through the pipe line. If the pipe line is completely closed at the other end, very high pressures can be generated in the pipe line; but if a plunger similar to the pump plunger is placed there, this will move in synchronism with the pump plunger, and is therefore able to do work on some type of machine. To prevent excessive rise of pressure in the pipe line when the sychronising plunger is stopped, capacity analogous to a condenser in an electric circuit is put in the pipe line, and if all machines are cut off a stationary wave is formed and theoretically no energy is given to the system by the generator. It is desirable that connexions to machines along the pipe line shall be made at ¼ wave-length points. Machines tapped in at half wave-length points along the pipe will be self-starting and stable in running, while those at the quarter wave-length and three-quarter wave-length will not be self-starting. If, however, a machine is started at half wave-length along the pipe, then a machine at a quarter wave-length will start; and if a machine is started at a wave-length along the pipe, then machines at a quarter and three-quarter wave-length will start. That this is so can be seen by examining the changes of pressure that take place at these points, when there is a stationary wave, and when there is a progressive wave superimposed on the stationary wave.

The principle has been successfully applied to controls on aeroplanes, to the working of rock-drilling machines, and to riveters. A description of the special transmission pipes to resist the high pressures generated, and the mechanism for rotating the rock drill, is given in the paper.

University and Educational Intelligence.

ABERDEEN.—The University Court has agreed to refit the Botanical Museum in Old Aberdeen, prior to the occupation of the new botanical department which is at present being built there. It has also agreed to make provision for increased laboratory accommodation for the department of chemistry.

CAMBRIDGE.—Mr. T. M. Cherry, Trinity College, has been elected to an Isaac Newton studentship, and the tenure of the studentship of Mr. W. M. H. Greaves, St. John's College, has been renewed for one year.

Smith's prizes have been awarded to Mr. J. C. Burkill, Trinity College, for an essay on "Functions of intervals and the problem of area," and to Mr. A. E. Ingham, Trinity College, for an essay on "Mean value theorems in the theory of the Riemann Zeta-Function." Rayleigh prizes have been awarded to Mr. E. F. Collingwood, Trinity College, for an essay on "The formal factorisation of an integral function of finite integral order," to Mr. W. R. Dean, Trinity College, for an essay on "The elastic stability of a plane plate," to Mr. E. C. Francis, Peterhouse, for an essay on "The Denjoy-Stieltjes integral," to Mr. C. G. F. James, Trinity College, for an essay on "The analytical representation of systems of space curves," and to Mr. M. H. A. Newman, St. John's College, for an essay "On discontinuities of functions of a single real variable."

The subject proposed for the Adams prize for the period 1923–4 is "The physical state of matter at high temperatures." Investigation is suggested of the statistical equilibrium of an assemblage of atoms in various ionised and quantised states together with free electrons and radiation. The essay may deal, however, in any way with the simplifications or the complications which appear in the properties of matter at high temperatures.

The Special Board for Oriental Studies will proceed to the election of the Eric Yarrow student in Assyriology early next term.

The Board of Research Studies in publishing its third report announces that the number of research students has risen to 179. Of these about two-thirds are working on the scientific side; chemistry and physics have the largest number, followed by botany, agriculture, and biochemistry.

Grants from the Gordon Wigan fund have been made to Prof. Punnett for plant-breeding experiments, to the Museum of Zoology for cases, to Prof. Gardiner for a centrifuge and incubator, to Mr. Harker for sections of rocks, and to Prof. Seward for sections of fossil plants.

DURHAM.—The council of Armstrong College, Newcastle-upon-Tyne, invite applications for the chair of philosophy. The latest date for the receipt of applications and testimonials is May 1. They should be sent to the Registrar.

LONDON.—The following doctorates have been conferred:—*Ph.D. in Science:* Mr. M. V. Gopalaswami of University College for a thesis entitled "Economy in Motor Learning"; Mr. A. M. Mosharrafa of King's College for a thesis entitled "The Quantum Theory of Spectral Series"; Mr. W. S. G. P.

Norris of the Imperial College (Royal College of Science) for a thesis entitled "The Formation and Stability of Spirane Hydrocarbons"; and Edith H. Usherwood of the Imperial College (Royal College of Science) for a thesis entitled "(i.) The Formation of Heterocyclic Rings involving Reactions with the Nitroso- and Nitro-groups in their various Tautomeric Modifications; (ii.) Experiments on the Detection of Equilibria in Gaseous Tautomeric Substances."

A post-graduate scholarship in science of the yearly value of 125*l.*, for two years, is being offered to Bedford College graduates for award in June next. Further information will be furnished upon application, by the Secretary of the College, Regent's Park, N.W.1.

MANCHESTER.—Mr. R. S. Adamson has resigned his post as senior lecturer in botany on his appointment to the Harry Bolus chair of botany in the University of Cape Town.

Mr. C. R. Christian has been appointed temporary demonstrator in pathology.

The Court of Governors has authorised the conferment of the following honorary degrees: *D.Sc.*: Prof. Niels Bohr, Copenhagen; Prof. F. G. Hopkins, Cambridge; and Mr. W. B. Worthington, president of the Institution of Civil Engineers, 1921–1922.

WE have received from the newly constituted University of Lithuania, Kaunas (Kovno), a copy of a bilingual—Lithuanian and English—calendar. The University, which was opened in February 1922, has the following faculties: theology and philosophy, humanities, law, mathematics and natural sciences, medicine, and technical science (engineering, chemical technology, architecture, etc.). It has 45 professors, 37 docents, and 35 members of the junior teaching staff, while there are more than a thousand students. It appeals to cultural institutions to help in the establishment of a library by sending books and other publications.

LOUGHBOROUGH COLLEGE celebrated its first presentation day on March 10, when the College diploma was conferred on some 250 students of the following departments: mechanical and civil engineering (69), electrical (31), automobile (32), pure and applied science (10), commerce and economics (88), training of teachers (31). The Minister of Labour, Sir Montague Barlow, who presented the diplomas and gave an address, remarked that the College is carrying out a very interesting experiment in undertaking a course which combines very closely theoretical studies and practical experience. This feature, to which we directed attention in our issue of October 21, p. 562, aims at securing for engineering students advantages comparable with those which a School Hospital gives to medicals. An essential principle of management of the instructional factory is that the output should be saleable. During the war the College trained more than 2300 munition workers, and at its close inherited the fine buildings erected for this work as well as valuable engineering equipment. Among the post-war students have been more than 500 enrolled under the scheme of grants for higher education for ex-service students; 237 of them have taken the diploma, and of these 138 have been satisfactorily placed in employment. The number of private fee-paying students enrolled is 343. There are students from Australia, South Africa, India, and many foreign countries. The College aims at a normal enrolment sufficient to enable the productive work scheme to be carried on as a commercial and economic enterprise.

Societies and Academies.

LONDON.

Royal Society, March 15.—J. A. **Carroll**: Note on the series-spectra of the aluminium sub-group. In contradistinction to the alkali metals, the highest terms in the known series-spectra of the elements of the aluminium sub-group are the common limits of the sharp and diffuse series, and not the limits of the principal series. Measurements of the ionisation and resonance potentials for thallium suggested that there might be a yet undiscovered principal series in the far ultra-violet, the limit of which would be the greatest term and would correspond with the normal state of the thallium atom. Against this is the absence of positive evidence of such a series, and the easily reversible nature of the lines of the subordinate series in the arc spectra. Evidence as to the normal state of the atoms is afforded by an investigation of the absorption spectrum of the cool vapour of one of the elements in question, *e.g.* thallium. The lines were members of the subordinate series, thus confirming the original series arrangement. The results accord with the latest developments of Bohr's theory.—W. E. **Curtis**: The structure of the band spectrum of helium.—II. Seven of the doublet bands previously examined by Fowler have been studied in detail. The structure of the bands, in the main, is in agreement with the requirements of the quantum theory; some discrepancies are discussed in connexion with Kratzer's half-quantum hypothesis. Values for the moments of inertia of the molecules concerned are derived by a graphic method. Several perturbations are recorded (the first examples in this spectrum) and their significance is discussed.—G. C. **Steward**: Aberration diffraction effects. Diffraction theory would indicate that the image of a luminous point, given by a symmetrical optical system, should be a system of luminous rings, and this was investigated by Airy in 1834; geometrical theory leads to a consideration of several types and orders of aberration, and the modification of the "ideal" diffraction pattern produced by these geometrical aberrations is discussed. The method adopted depends upon the Eikonal function of Bruns. Aberration diffraction effects are dealt with, assuming that the stops of the optical system are circular, with centres upon the axis of symmetry. Other stops used, namely, the usual circular aperture, but with the central portion stopped out, one (or two parallel) narrow rectangular aperture, and a semi-circular aperture are also considered.—Lord **Rayleigh**: Further observations on the spectrum of the night sky. Specially designed spectrographs having a working aperture of $f/\cdot9$ are described. The northern and southern horizons have been photographed simultaneously on the same plate, and the aurora line recorded almost down to the horizontal direction in each. There is no marked difference of intensity between them. The negative nitrogen bands appear fairly often in photographs taken in the north of England, but similar spectra taken in the south of England do not show them. They are always strong in the Northern Lights in Shetland. Two bright lines or bands in the blue and violet were always observed, the approximate positions, determined on the *very* small scale spectra, being 4200 and 4435. Their origin is not known. In addition, there is the aurora line 5578, also of unknown origin, and the dark Fraunhofer lines H and K.—Lord **Rayleigh**: Studies of iridescent colour, and the structure producing it. IV.—Iridescent beetles. Some of the iridescent beetles which have striking metallic colours show band systems in the spectrum of the reflected light.

That from *Pelidnota sumptuosa* shows a central maximum bordered on either side by subordinate maxima in exactly the way that reflection from a uniformly spaced assemblage of 34 thin plates would require. In the spectrum from one of the golden beetles, *Callodes parvulus*, the bands are accounted for on the supposition of two assemblages, each consisting of several reflecting planes, the distance between the assemblages being about 8μ.—J. W. **Nicholson**: Oblate spheroidal harmonics and their applications.—J. W. **Nicholson** and F. J. **Cheshire**: On the theory and testing of right-angled prisms.—J. C. **McLennan** and D. S. **Ainslie**: On the fluorescence and channelled absorption spectra of caesium and other alkali elements. Caesium exhibits a fluorescence and a channelled absorption spectrum in the neighbourhood of $\lambda = 8000$ when the vapour of the element is traversed by white light. In the absorption spectrum, bands separated by intervals that were simple multiples of 24 Å were found. Like sodium, potassium exhibits channellings in its absorption spectrum, in the neighbourhood of the second member of its doublet series. Indications have been obtained of channelling in the absorption spectrum of lithium in the near ultra-violet region.—W. **Stiles**: The indicator method for the determination of coefficients of diffusion in gels, with special reference to the diffusion of chlorides. The coefficient of diffusion increases at a greater rate per degree rise in temperature the higher the temperature; the relation between coefficient of diffusion and temperature in gels is thus not linear as is usually assumed for free diffusion in water. The coefficient of diffusion decreases with increasing concentration of gel and increases with decreasing concentration of the diffusing salt. Empirical expressions are given for these relationships.—H. T. **Flint**: A generalised vector analysis of four dimensions. An account is given of an invariant vector calculus in a notation which is the natural generalisation of that of Gibbs. Contravariant and covariant vectors are related by means of an operator—the extended idem-factor, and tensors are introduced as dyadics and polyadics. The expressions familiar in the tensor calculus of Riemann and Christoffel appear very simply in the analysis. Separated points are connected by the geodetics, and a simple definition of parallelism at two points leads at once to the Weyl parallel displacement relations.

Geological Society, February 28.—Prof. A. C. Seward, president, and, afterwards, Prof. W. W. Watts, vice-president, in the chair.—S. Hazzledine **Warren**: (1) The late glacial stage of the Lea Valley (Third Report). One new section found occurred at the level of, and in the area occupied by, the Middle or Taplow Terrace, whereas all the other sections were in the Low Terrace. It consisted of a bed of seed-bearing clay, in the middle of an old gravel-pit partly built over. The Taplow deposits yield a fairly temperate fauna and flora. The site is close to the head of a small streamlet, and it is assumed that the Arctic plant-bed is of Low-Terrace or Ponders-End date, and that it represents the silting of a stream which flowed across the Taplow Terrace. According to a report on the Arctic flora by Mrs. E. M. Reid and Miss M. E. J. Chandler, there is nothing to distinguish the flora from that of the previously-described localities of the Lea Valley. (2) The *Elephas-antiquus* bed of Clacton-on-Sea (Essex), and its flora and fauna. The deposit fills a deep, narrow, steep-sided, river-channel which apparently flowed into the Thames when that river occupied the deep channel now submerged off the coast of Essex. The Clacton bed yields evidence of an abundant flint-industry which is one of the best-known representatives of the Mesvinian series. This is of Late Chellean or Early Acheulean date, although it shows no cultural connexion with those industries, but it may be the precursor of Mousterian. The deposit is also rich in mammalian remains. Appended to the paper are detailed reports on the palæontology.

Linnean Society, March 1.—Dr. A. Smith Woodward, president, in the chair.—J. N. **Halbert**: Notes on the Acari, with descriptions of new species.—C. F. M. **Swynnerton**: Aspects of African woodland formations. Rain-forest, coppice, and thicket due to grass-fires, the means of prevention from injury by such fires, and the preservation of the forests by careful nurture, were dealt with.

Aristotelian Society, March 5.—Prof. A. N. Whitehead, president, in the chair.—E. S. **Russell**: Psychobiology. Physico-chemical method is applicable to many of the phenomena of life, but it fails of complete success because it cannot take account of the individuality and striving of the living thing, nor its flexibility of response. Also it cannot take into consideration, as an active factor, the past history of the organism, for it must regard past history as completely summed up in present state. The true alternative to the materialistic view is not vitalism, but a psychobiological view based upon a monadistic philosophy. Both the movements and the morphogenetic responses of the organism must on this view be interpreted as actions of a living individuality, carried out in response to its own sensed environment, in pursuance of the fundamental conative impulses which are the core of its being.

Zoological Society, March 6.—Sir S. F. Harmer, vice-president, in the chair.—Mr. **Caldwell**: A case of apparent melanism in Tippelskirch's Giraffe (*Giraffa camelopardalis tippelskirchi*).—H. G. **Cannon**: A note on the zoæa of the land-crab, *Cardisoma armatum*.—Miss L. E. **Cheesman**: Notes on the pairing of the land-crab, *Cardisoma armatum*.—C. F. **Sonntag**: The comparative anatomy of the tongues of the mammalia.—VIII. Carnivora.—T. H. **Ring**: The elephant-seals of Kerguelen Land.—R. **Kirkpatrick**: On the tunicate *Rhizomolgula globularis* Pallas. No. 24. Results of the Oxford University Expedition to Spitsbergen, 1921.

Society of Public Analysts, March 7.—Mr. P. A. Ellis Richards, president, in the chair.—A. **Lucas**: The examination of firearms and projectiles. A particular weapon may sometimes be recognised by the rifling marks imprinted on a bullet, while the nature of the fouling left in the barrel after the weapon has been fired may afford information as to the nature of the original powder and also, in some cases, the period that has elapsed since the last discharge. The composition, dimensions, and markings on bullets, slugs, etc., are described, and directions are given for the reproduction of rifling marks and for the chemical analysis of projectiles.—R. C. **Frederick**: The interpretation of the results obtained in the analysis of potable waters.—S. B. **Phillips**: Determination of the purity of vanillin. After reviewing the various methods proposed from time to time the author described two processes for estimating vanillin—one volumetric, and the other gravimetric.

EDINBURGH.

Royal Society, March 5.—Prof. F. O. Bower, president, in the chair.—F. O. **Bower**: The relation of size to the elaboration of form and structure of

the vascular tracts in primitive plants. Measurements of the diameters of the whole part (stem or petiole) and of the conducting tract (stele or meristele) in many living and fossil plants show that increasing size is accompanied by increasing complexity of structure. There is a tendency in the various organs of plants to decentralise their conducting tracts as the part enlarges, and to advance them in greater or less degree towards the periphery of the transverse section. This decentralisation is carried out homoplastically, with details differing in the several parts affected, in various primitive organisms. It is not inherent in any one organ. The final result may be a convergence of structure in different plants, and in different parts of the same plant. This is illustrated (i.) by the solenostele, (ii.) by the zygopterid petiole, (iii.) by the Dipterid petiole, (iv.) by the petiole of Anachoropteris. Stellation of the stele or of the xylem, medullation, decentralisation of the stele, and finally its disintegration, so far as they are functions of increasing size, must lose grade for comparative purposes.—Miss Margery **Knight**: The life history and cytology of *Pylaiella litoralis*. Development and the reproductive processes were described. This involved a detailed cytological study of the organism. In particular it is shown that there is no obligate relationship between cytological features, somatic characters, and reproductive organs. The object of the paper is to emphasise this fact, and thereby to reopen discussion on the value of cytological characters in phyletic study.—A. **Steuart**: An electric clock, with detached pendulum and continuous motion. The speed of the driving electric motor is controlled by a pendulum, without throwing any work on the latter. A gravity arm acts on the pendulum, and then short-circuits a resistance in the motor armature circuit. The motor raises the gravity arm, and so replaces the resistance. A powerful turret clock and a silent regulator clock were demonstrated.

SHEFFIELD.

Society of Glass Technology, February 21.—Prof. W. E. S. Turner, president, in the chair.—W. W. **Warren**: Organising for production from pot furnaces. The function of a furnace is to melt glass. For most purposes, circular gas furnaces, either regenerative or recuperative, are to be preferred to those of rectangular shape. Among the advantages of working to a time-table in the matter of founding and working during definite periods are: (*a*) the responsibility devolved on the producer and furnacemen to have glass ready in time for their co-workers; (*b*) mixing, filling pots, and all labour subsidiary to glass-making work smoothly in an appointed groove. Informal talks with the men's committee, with a blackboard for illustrating points and explaining figures, rarely failed to convince them that foreign competitors' methods and prices were a challenge to business sport. But if there were rewards at the end of the production programme, the men must share.—F. W. **Hodkin** and Prof. W. E. S. **Turner**: The effect of boric oxide on the melting and working of glass.—Violet **Dimbleby**, S. **English**, and Prof. W. E. S. **Turner**: Some physical properties of boric oxide-containing glasses. Prof. Turner presented these two papers. The new British chemical glass, American pyrex glass for chemical ware and cooking ware, and various forms of illuminating glasses, all contain boric oxide. Although the addition of boric oxide to a silicate glass brought a marked increase in the durability, this beneficial effect only holds good up to a certain point. Similar inversions in other properties, *e.g.* in the thermal expansion, the annealing temperature, the density, and refractive index, had also been found.

BALANCES & WEIGHTS

REYNOLDS & BRANSON, LTD.

LABORATORY FURNISHERS AND MANUFACTURING CHEMISTS.

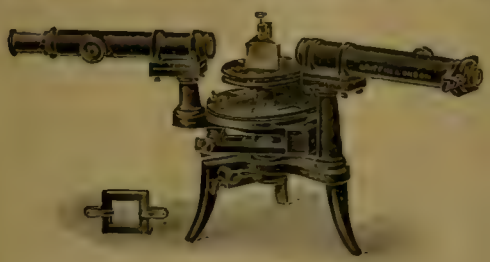
Balance, Analytical, Rystos New Model. Improved vertical movement of rider hook, rider scale running from end to end of beam and plumb line. The bearings are agate throughout; the beam of hard magnalium. Base of black crystal. Mahogany case with counterpoised front, hinged side doors and sliding back and brass levelling screws. To carry 200 grammes, sensitive to ½th milligramme, or ⅒th milligramme with a less load £14 0 0

Balances renovated and repaired in our own Workshops.

For Analytical and other Balances and Weights, see special Catalogue. Catalogues of Chemical and Physical Apparatus and Chemicals. Post Free on request.

14 Commercial Street, Leeds.

SPECTROMETERS



Particulars and Prices on application to—

NEGRETTI & ZAMBRA
38, HOLBORN VIADUCT, E.C.1.
LONDON.

UNIVERSITY OF ABERDEEN.

VACATION COURSE, JULY 16-27, 1923.

SHORT COURSES BY PROFESSORS AND LECTURERS.

Group I. LITERARY AND ARTISTIC STUDIES, including: Present-day Germany; Recent Advances in Education; The Study of Words; Celtic Literature; Public Speaking; Recent Advances in Palæography.

Group II. SOCIAL AND HISTORICAL STUDIES, including: The Economic Evolution of the XIXth Century; The Settlement of St. Columba in Iona; The Call of John Knox to Reformed Ministry, at St. Andrews; Scottish Civilisation in the Early Centuries, A.D.; Cosmogonies, Old and New; Recent Excavation in Palestine; The Chapel, King's College; The Law of Insurance; Johann Sebastian Bach; Bach's Original Hymn Tunes, illustrated by a choir of voices.

Group III. SCIENCE, including: Evolution of a Land Flora; Bio-Chemistry; Modern Science and Garden Craft; The Applications of Meteorology to Aviation, Gunnery, etc.; Public Health; The Nervous System of Man; Sidelights on Human Disease from the Comparative Pathology Standpoint; Some Recent Advances in Physiology; The Hive Bee in Health and Disease; Recent Progress in Parasitology; Catalysis and its Industrial Application.

The lectures will be given in the forenoons.
Historical and Scientific Excursions will be arranged for the afternoons.
Fee Two Guineas for the whole Course; One Guinea for a week.
For further particulars apply to the SECRETARY to the UNIVERSITY OF ABERDEEN.

DICKINSON RESEARCH TRAVELLING SCHOLARSHIP IN MEDICINE.

The Trustees invite applications for the Dickinson Research Travelling Scholarship in Medicine.

The Scholarship is of the value of £300, tenable for one year. Candidates must have graduated at the University of Manchester in Medicine and Surgery in any one of the three academic years immediately preceding the award of such Scholarship, and must have earned distinction in so doing.

A copy of the Regulations governing the Scholarship can be obtained from the undersigned, to whom six copies of application should be sent not later than Tuesday, May 1, 1923.

FRANK G. HAZELL,
Manchester Royal Infirmary,
March 2, 1923. Secretary to the Trustees.

ROYAL HOLLOWAY COLLEGE (UNIVERSITY OF LONDON).

The Easter Term commences on Monday, April 23, 1923. THE SCHOLARSHIP EXAMINATION in 1924 will be held in MARCH instead of APRIL, and the closing date of entry will be FEBRUARY 9, 1924. Further particulars may be obtained from the SECRETARY, Royal Holloway College, Englefield Green, Surrey.

H.M. SIGNAL SCHOOL, R.N. BARRACKS, PORTSMOUTH.

Applications are invited for two vacancies for ENGINEERS, GRADE II., in the LABORATORY SECTION of the above School. The duties concern the development of Wireless Telegraphy, etc., for Naval purposes. Preference given to candidates possessing an Honours Degree in Physics or Electrical Engineering.

The salary scale is £150, rising by annual increments of £10 to £300 per annum, plus bonus based on the average cost of living figure. The minimum pay plus bonus at present is £244 per annum.

The appointments are not established and the Federated Universities Superannuation Scheme is applicable.

Applications giving full particulars of the candidate's experience, War Service, etc., should be addressed to THE SECRETARY OF THE ADMIRALTY (C.E.), Admiralty, S.W.1, from whom further particulars of the duties, etc., can be obtained.

UNIVERSITY OF LONDON.

The Senate invite applications for the ASTOR CHAIR of PURE MATHEMATICS tenable at University College. Salary £1000 a year. Applications (12 copies) must be received not later than first post on May 24, 1923, by the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7, from whom further particulars may be obtained.

BEDFORD COLLEGE FOR WOMEN (UNIVERSITY OF LONDON).

The Council of Bedford College invite applications for the posts of (i) DEMONSTRATOR in ORGANIC CHEMISTRY; (ii) DEMONSTRATOR in INORGANIC and PHYSICAL CHEMISTRY; (iii) PART-TIME ASSISTANT in LATIN.

Candidates must have an Honours Degree or its equivalent.
Applications must be received not later than Saturday, April 28.
For all particulars apply to the SECRETARY, Bedford College, Regent's Park, N.W.1.

UNIVERSITY OF LONDON.

The Senate invite applications for the following UNIVERSITY READERSHIPS tenable at Bedford College:

READERSHIP in GEOGRAPHY, salary £700 a year.
READERSHIP in MATHEMATICS, salary £500 a year.

Applications (12 copies) for either post must be received not later than first post on April 13, 1923, by the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7, from whom further particulars may be obtained.

UNIVERSITY OF LONDON.

The Senate invite applications for the following posts:

UNIVERSITY CHAIR of PHYSIOLOGY tenable at King's College. Salary £800 a year.
UNIVERSITY READERSHIP in Physics tenable at Guy's Hospital Medical School. Salary £400 a year.

Applications (12 copies) must be received not later than first post on May 19 and 16, 1923, respectively, by the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7, from whom further particulars may be obtained.

UNIVERSITY OF LONDON, KING'S COLLEGE.

The Delegacy require the services of a DEMONSTRATOR in BOTANY (man). Salary £250 per annum. The duties will commence in April. Opportunities will be given for research work.

Applications, with two copies of not more than three recent testimonials, should be received not later than April 10 by the SECRETARY, King's College, Strand, W.C.2, from whom further particulars may be obtained.

CHELSEA POLYTECHNIC, CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.** Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.** Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement, Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.** Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

SIDNEY SKINNER, M.A.,
Telephone: Kensington 809. Principal.

BATTERSEA POLYTECHNIC. LONDON, S.W.11.

Principal—ROBERT H. PICKARD, D.Sc., F.R.S.

Full-time day courses in Engineering (Mechanical, Civil and Electrical), Chemistry, Flour Milling, Physics, Mathematics.

Students prepared for University of London Internal Degrees, A.I.C. Examination, and Polytechnic Diplomas.

Evening courses in Engineering, Chemistry, Physics, Mathematics, and Music in preparation for Internal Degrees in the Faculties of Science, Engineering and Music.

Library, Writing Room, Common Rooms, Refreshment Rooms, large Athletic Ground, etc.

Particulars on application to the PRINCIPAL.

TO SCIENTISTS AND RESEARCH STUDENTS.

THE INTERNATIONAL BIBLIOGRAPHICAL SERVICE BUREAU,

employed by British Government Departments, University Professors, etc., supplies complete Continental and American bibliographies on any scientific, literary, or medical subject. Chemical work a speciality. Extracts made.

Headquarters: Vienna. English representative: "ALEXANDRIAN," 1A Longridge Road, Earl's Court, S.W.5.

FIRM OF CONSULTING CHEMISTS

in North of England require Chemist with experience in organic work. Apply, giving particulars of training, experience, etc., to Box No. 68, c/o NATURE Office.

JUNIOR CHEMIST WANTED for Hospital

Laboratory in North Wales. Graduate with training in physiological chemistry preferred. Reply stating age, particulars of training and salary required to Box 67, c/o NATURE Office.

NO. 2787, VOL. 111]

National Health and Medical Research.[1]

THE elaborately detailed report of the Medical Research Council for the past year gives much food for thought, whether we receive it in the spirit of the tax-payer, anxious to be assured that his contribution to the national health is being worthily expended, or in the spirit of the watchman, eager only for a sign, but untroubled by detail. We all have in us something of the tax-payer and, let us hope, something more of the watchman, so let us see how these respective parts of us are catered for in the Council's report. Whether we are able to appreciate its contents or not, we, as tax-payers, have always demanded this sort of governmental report. Does it not concern the disbursement of 130,000*l.*, or something like a halfpenny per head of the population, on the pursuit of new knowledge that is to alleviate human suffering? Unthinking lay and even medical critics might regard it as a perilous investment. Were they holders of cinema shares, they would probably accept without question a similar disbursement to the parents of a Jackie Coogan.

If, then, we expect to find definite assurance that new knowledge leading directly and immediately to improvement in the health of the community has been acquired, we shall be disappointed. The average newspaper, keen only for sensation, would vote it dull. But a closer study of the report, including its admirable introductory chapter by the special Committee of the Privy Council, is calculated to bring to the more responsive of us the conviction that inability to appreciate springs from our own ignorance and short-sightedness. We gather, in fact, that the machine which registers advance in scientific medicine resembles a piece of complicated clockwork, the wheels of which represent movements in all the biological and physical sciences, not excluding mathematics. We note, for example, how the Hill katathermometer—an instrument of precision for measuring the cooling power of the atmosphere—may be made to afford a most valuable index of conditions affecting the efficiency of the worker in factory and workshop. We note also recent progress in our knowledge of the biological action of sunlight, and its remarkable influence on diseases such as rickets. A new field is here opened.

The discovery of insulin by the Toronto workers is alluded to at length. We gather that a method of preparing a potent product of consistent uniformity has not yet been achieved, but doubtless this difficulty will yield to further research. It is worth reflecting that this new knowledge might still be withheld from us, were it not for the elaboration in recent years of

[1] Report of the Medical Research Council for the year 1921–22. (Published by His Majesty's Stationery Office.) 3*s.* 6*d.* net.

quantitative tests for sugar in the blood. It is probable that many a preparation of pancreas has failed, in the past, to become established because its physiological activity could not be satisfactorily tested and recourse was limited to casual clinical trials. When one considers the plethora of commercial pancreatic preparations already on the market, which claim to contain the specific sugar-destroying principle, it is comforting to know that the Medical Research Council has taken the action it has, and that its own experts are actively engaged in studying methods that may yield preparations of uniform potency. In connexion with these difficulties, we note with some interest Dudley's work at the National Institute in refining pituitary extract. Apparently, the further the purification was carried, the less potent the substance became physiologically. This is not the first time that such stumbling-blocks have interfered with attempts to refine biologically potent principles contained in organ extracts or in culture fluids which have served for the growth of micro-organisms.

It would be superfluous to attempt to enumerate the many lines along which research is being pursued, either by expert workers at the National Institute or by the many outside specialists whose work the Medical Research Council encourages or finances; nor can we mention even the terms of reference of the numerous committees and sub-committees which have taken upon themselves the task of co-ordinating attack upon a multitude of problems in all fields of scientific medicine and hygiene. Membership of these committees is no sinecure, and it is notorious that much self-denying work is performed. Verily, the appreciative tax-payer can have no reason to grumble at the way in which his exiguous contribution to the community's health is expended.

Now what has the report to say to the watchman seeking for a sign? We believe the organisation of research under the ægis of a responsible body of scientific advisors is a valuable national asset. Will such organisation interfere with the individual freedom of the research worker? Is there a danger that the extension of the team-principle and the laying down by a higher authority of precise research programmes may stifle what originality the worker may possess? The answer is, we believe, that there are men who work best in a team and men who prefer to work alone, and that there is ample room for both types. There are periods both in war and in peace when stocktaking of knowledge is essential if we are again to make advance into the unknown. The present is one of those times of national stocktaking in medical science. The very fundamentals of many departments of medical science require revision. A doyen of the chemical world recently referred to certain developments and proposals in biological chemistry as being simply re-search, with the accent and insistence on the first syllable.

The statement is both true and false. Simple reconstruction must inevitably form an integral part of modern research. Possibly the biological sciences, on which advance in scientific medicine mainly hangs, contain a greater proportion of inexact, un-coordinated, and incomplete statement than the so-called exact physical sciences. Every advance in the latter reacts on biology, necessitating re-search in some form or other. Co-ordinated investigation by teams is necessary in peace as in war, and the fruit will duly appear. The scientific investigation of deficiency diseases—a war-time necessity—has developed into something like a science of its own. The organised investigations on anærobic bacteria—another war-time necessity—which was perhaps a very typical example of a re-search, has already borne abundant fruit in recent exact studies of such diseases as botulism and braxy.

What of the night? The morning cometh.

J. C. G. L.

The Fourier-Bessel Function.

(1) *A Treatise on Bessel Functions and their Applications to Physics.* By Prof. A. Gray and G. B. Mathews. Second edition prepared by A. Gray and Dr. T. M. MacRobert. Pp. xiv+327. (London: Macmillan and Co., Ltd., 1922.) 36s. net.

(2) *A Treatise on the Theory of Bessel Functions.* By Prof. G. N. Watson. Pp. viii+804. (Cambridge: At the University Press, 1922.) 70s. net.

THE function to which these volumes are devoted received its name from the astronomer Bessel, 1824, on introducing it for the coefficients in the expansion of radius vector, and true or eccentric anomaly in a Fourier series of sines and cosines of multiples of mean anomaly or time. Two years before, in 1822, Fourier had encountered the same function essentially in his analytical theory of heat, and his variable is the square of the variable of Bessel.

The function is, however, first met in a dynamical problem, of the oscillation of a vertical chain, investigated by Bernoulli, 1738, and here the Fourier form is the natural one to use. The oscillation is replaced by a steady motion of permanent shape in a chain hanging down, and revolving bodily, and this is easy to realise experimentally; the plane oscillation is then seen in the shadow on a vertical wall.

Take the condition of relative equilibrium of a length x above the lowest point, where it is assumed that the displacement is small enough for vertical distance x

and the length of the chain to be undistinguishable, so that the tension $T=\sigma x$, as at rest, σ the line density.

Putting $g=\omega^2 l$, where l is the height of the equivalent conical pendulum revolving at the same rate ω, the equation of relative equilibrium is

$$T\frac{dy}{dx}+\int\sigma\frac{y}{l}dx=0,\quad x\frac{d^2y}{dx^2}+\frac{dy}{dx}+\frac{y}{l}=0,$$

having a solution $y=b\mathrm{F}(x/l)$, where $\mathrm{F}(x)$ is Fourier's function, defined by the series

$$\mathrm{F}(x)=\Sigma\frac{(-x)^k}{(1\overline{k})^2}.$$

The sort called *Furniture Chain* is suitable for experiment: the links are small hollow brass spheres, joined up by rivet links, and it is sold in various sizes.

A length of the large size of about 4 feet is suitable for whirling round by hand, and producing a curve in 1, 2, 3, 4, . . . waves, showing to the eye the position of the first roots of $\mathrm{F}(x)=0$.

Standing up on a chair or the table, a length of 8 or 12 feet of the smaller size may be set in rotation by the dynamobile toy. The chain springs at once into a series of waves, where the higher roots are seen and their spacing, prolongation of the figure at the end of Gray.

The chain can also be used to show off a real catenary curve, instead of the string recommended in Routh—much too kinky and destitute of flexibility to form a good catenary. And dropping the chain from a height is a good problem on a steady blow, equivalent of a series of impacts of the discrete links.

With a rotating chain of variable density, σx^n, the tension $T=\sigma x^{n+1}/(n+1)$, and the equation changes to

$$T\frac{dy}{dx}+\int\sigma x^n\frac{y}{l}dx=0,\quad x\frac{d^2y}{dx^2}+(n+1)\frac{dy}{dx}+(n+1)\frac{y}{l}=0,$$

the solution of which may be written

$$y=b\left(-\frac{d}{dx}\right)^n\mathrm{F}(n+1)\frac{x}{l},$$

and l is the length of the subtangent at the lowest point.

For if $u=\mathrm{F}(x)$ is the solution of the equation

$$x\frac{d^2u}{dx^2}+\frac{du}{dx}+u=0,$$

differentiating n times, with $y=(-d/dx)^n u=\mathrm{F}_n(x)$,

$$x\frac{d^2y}{dx^2}+(n+1)\frac{dy}{dx}+y=0,\quad y=\mathrm{F}_n(x)=\Sigma\frac{(-x)^k}{\Pi(n+k)\Pi k},$$

the Fourier function of the nth order.

Here n may be changed into $-n$, and the differentiation into an integration, making $\mathrm{F}_{-n}(x)=x^n\mathrm{F}_n(x)$.

Gray's function $\mathrm{I}_n(t)$ (p. 20), is the equivalent of $\mathrm{F}_n(-x)$.

But with the variable $z=2\sqrt{x}$ of the Bessel form, the equation changes to

$$z^2\frac{d^2y}{dz^2}+(2n+1)z\frac{dy}{dz}+z^2y=0,$$

and this, with $y=(\tfrac{1}{2}z)^{-n}u$, into

$$z^2\frac{d^2u}{dz^2}+z\frac{du}{dz}+(z^2-n^2)u=0,$$

defining $u=\mathrm{J}_n(z)=(\tfrac{1}{2}z)^n\mathrm{F}_n(\tfrac{1}{4}z^2)$, and the simplicity disappears of the derivation of $\mathrm{J}_n(z)$ from $\mathrm{J}_0(z)$ by successive differentiation or integration; factors intervene of powers of z.

The interlacing of the roots of F_n and F_{n+1} is evident from the differentiation; and there is an infinite series of positive roots, but none are negative.

This chain of variable density could be imitated by a flexible lattice blind, of appropriate curvilinear outline, hanging vertically, and rotating bodily.

Lecornu's problem of the oscillation of a large weight, raised or lowered by a chain of which the density may be neglected, is seen in operation in the erection of the tall buildings springing up around; it gives rise to similar expressions.

A Fourier function of fractional order arises in the question of the stability of a tall mast or tree, or of a chimney stalk when it begins to flinch on the foundation, and starts to curl over from the vertical; illustrated experimentally by a thin steel wire clamped in a vice.

With uniform cross-section, the equation is

$$ek^2\frac{d^2p}{dx^2}+xp=0,\quad \frac{1}{p}\frac{d^2p}{dx^2}+\frac{x}{ek^2}=0,$$

where $p=dy/dx$, k is the radius of gyration of the horizontal section across the plane of flexure, and e is Young's elastic length of the material, quotient of the modulus of elasticity divided by the density.

Every linear differential equation of the second order is reducible, by a change of independent and dependent variable, to the canonical form

$$\frac{1}{u}\frac{d^2u}{dx^2}+\mathrm{I}=0,$$

and when the differential invariant $\mathrm{I}=kx^n$, any power of x, the form to which Riccati's equation is reducible, the equation is reduced to Fourier's form by a mere change of the independent variable to

$$z=\frac{kx^{m+2}}{(m+2)^2},$$

and becomes Fourier's equation for

$$u=\mathrm{F}_n(z),\quad n=-\frac{1}{m+2}$$

(Watson, p. 88).

Here with the uniform column on the verge of drooping from the vertical, $m=1$, $p=b\mathrm{F}_{-\frac{1}{3}}(x^3/9ek^2)$.

The smallest root of $F_{-\frac{1}{3}}=0$ is about 0·88, say $\frac{8}{9}$ (Watson); this makes the critical height

$$x=2(ek^2)^{\frac{1}{3}}=(\tfrac{1}{2}ed^2)^{\frac{1}{3}}$$

for a circular rod of diameter d.

For steel, we may take $e=250$ million cm, one quarter of a quadrant Q of the Earth, $\sqrt[3]{\frac{1}{2}e}=500$.

With a steel wire held in the vice vertical, one millimetre in diameter, $d=0{\cdot}1$ cm, the critical height $x=500\,d^{\frac{2}{3}}=107{\cdot}7$ cm, a little over one metre. As the height is increased through this length, the vibration becomes sluggish more and more, and finally ceases, and the wire droops.

The drooping of a candle on a hot day will give an illustration; also a field of corn when it is ripe, where, to obtain a complete solution, the weight of the head would require the introduction of the Fourier function of the second kind, or a Bessel-Neumann-Weber function (Gray, p. 14; Watson, p. 308); so too for the addition of a weight at the end of the vibrating chain.

Here the flexural elasticity keeps the rod, mast, or cornstalk vertical; a flexible chain cannot be made to stand upright; the sign of x would be changed in the relation, and the Fourier function has no negative root.

But a quasi-rigidity can be imparted, as in the reported rope trick of the Indian juggler magician, if our chain carries a gyroscopic flywheel in rapid rotation inside each link, like a pile of spinning tops, and then, as shown in *Phil. Mag.*, Nov. 1919, p. 506, the differential equation of the former result changes to the form

$$(a-x)\frac{d^2y}{dx^2}-\frac{dy}{dx}+\frac{y}{l}=0,$$

with x measured downward from the free end at the top; the solution is

$$y=bF\left(\frac{a-x}{l}\right),$$

and the first value of $y=0$ is given by $(a-x)/l=1{\cdot}44$. Thus a length x of the gyroscopic chain can be made to stand upright, given by $x=a-1{\cdot}44\,l$.

The whip and whirl of a revolving shaft has become a question of practical importance in the swift-running machinery of a turbine, internal-combustion flying-machine motor, and gyro-compass.

Here it is obvious that the shaft will depart from the straight form when the revolutions are equal to the lateral vibrations of the shaft at rest, held between the same bearings, the disturbing and restoring force being the same in the two cases.

The more general form of the differential equation, required when the cross-section and density varies as some power of x, will be

$$\frac{d}{dx}\left(x^q\frac{dy}{dx}\right)+kx^my=0,$$

and hence a change to the independent variable

$$z=\frac{kx^{m-q+2}}{(m-q+2)^2}$$

will lead to Fourier's equation of order

$$n=\frac{q-1}{m-q+2}.$$

The general solution of Riccati's equation is thus expressed by the Fourier function; and the condition that Riccati should have a solution in finite terms requires n to be half an odd integer.

Beginning with $n=-\frac{1}{2}$,

$$F_{-\frac{1}{2}}(x)=\Sigma\frac{(-x)^k}{\Pi(k-\frac{1}{2})\Pi k'}$$

$$F_{-\frac{1}{2}}(x)=\frac{1}{\sqrt{\pi}}\Sigma\frac{(-2\sqrt{x})^{2k}}{\Pi 2k}=\frac{\cos 2\sqrt{x}}{\sqrt{\pi}};$$

and a phase angle ϵ may be added to the variable $2\sqrt{x}$ to include both forms of the function.

Then the other Fourier functions of order half an odd integer are derived by an integration or differentiation with respect to x:

$$\sqrt{\pi}F_{\frac{1}{2}}(x)=-\frac{d}{dx}\sqrt{\pi}F_{-\frac{1}{2}}(x)=\frac{\sin 2\sqrt{x}}{\sqrt{x}},$$

$$\sqrt{\pi}F_{\frac{3}{2}}(x)=-\frac{\cos 2\sqrt{x}}{x}+\frac{\sin 2\sqrt{x}}{2x^{\frac{3}{2}}}=x^{-\frac{1}{2}}\sqrt{\pi}F_{-\frac{3}{2}}(x),$$

and so on.

The same simplicity of derivation is not so obvious in the table (Gray, p. 17) for $J_{n+\frac{1}{2}}(z)$, although the sines and cosines are replaced by sin, cos $(z+\epsilon)$.

Functions of this fractional order are of frequent occurrence in mathematical physics, as in the vibration of a sphere (Love's "Elasticity," Lamb's "Hydrodynamics") for the functions ψ_n and Ψ_n, solution of $(\nabla^2+m^2)\phi=0$, in the propagation of spherical waves or the conduction of heat; also for the function F_n of Bromwich and $\gamma\rho$ of Macdonald in electromagnetic waves; simplicity would be obtained if all these functions were referred to the Fourier form and classed there (*Phil. Mag.*, Nov. 1919, pp. 508, 526).

The Fourier function comes in useful for the discussion of a long flat tidal wave in an estuary or channel of vertical cross-section K, and surface breadth b, treated as slowly variable, on the assumption of K and b varying as x^q and x^m, simple powers of x.

The Fourier function is suitable, too, in the discussion of diffraction (Gray, Chapter XIV.), provided the area of a circular fringe is taken in the formula instead of the circumference or diameter.

The derivation, by differentiation and integration, of the Fourier function of different order marks it out as more appropriate than Bessel for the passage, in Lord Rayleigh's manner, of the tesseral harmonic $P_n^k(\mu)$ direct into a Fourier function $F_p(x=\frac{1}{4}m^2r^2)$ as the order

n is increased indefinitely (*Phil. Mag.*, Nov. 1919, p. 526).

In Gray's treatise the physical applications are kept in view throughout the book up to the end. The requirements are considered of the mixed mathematician. Not to start with general theory, but to give definite technical examples, to show how the problem may be reduced to the differential equation considered, he will consult the appropriate part of the book as the need arises, and will take for granted the discussion of details of pure analysis, on the validity of an expansion, definite integral expressions, asymptotic expansions, and all the niceties appealing to the pure mathematician of a logical metaphysical intellect.

These can be skipped by the physical student engrossed in a physical problem, and only anxious to dig out the facts and apply the formula to a concrete numerical application, for which the tables at the end of the book will give the requisite material.

The treatise of Watson has a different scope. A first short historical chapter cites name and date of the pioneers up to 1826 encountering the function in dynamical, astronomical, and heat problems, namely, Bernoulli, Euler, Fourier, Bessel.

After this introduction, all definite mention of the physical application is dismissed by Watson in the subsequent 800 pages, and the reader is not encouraged to lift his eye from the page and look up at any materialisation of the analysis, or to study a geometrical picture.

The book proceeds in what is now the conventional manner of a modern analytical treatise, stopping in a leisurely manner to emphasise and scrutinise every possible objection that may arise on the part of rigour. Those who like this work become uncommonly fond of it, and lose interest in a realisation of the ideas.

"Making possible the necessary degree of abstraction is one of the most important merits of mathematical logic."

The Bessel function has few attractive analytical qualities, and does not deserve elaborate treatment to the exclusion of more valuable interest, say of the elliptic function.

The students must be few to afford the time demanded for this subject, not to speak of the expense—for Watson's book, 70*s*.; and Gray's of 327 pages, at 36*s*.

We see the tax laid on knowledge by the price of all mathematical work; the expense of publication has risen far beyond anything contemplated in the old days of debate in the Mutual Improvement Society on the need of a free press and cheap diffusion of knowledge.

It is the fashion to-day to discard a redundant *i* in the name Bernoulli, as in the Bernoullianum Mathematical Museum in Basel, Basle, Bâle in Switzerland. But Maclaurin in his "Account of Newton's Philosophical Discoveries," 1750, spells the name Bernovilli, and here we see the etymological derivation and a reason for the restoration of the banished *i*.

G. GREENHILL.

A Yearbook of the Learned World.

Index Generalis: Annuaire général des Universités, Grandes Écoles, Académies, Archives, Bibliothèques, Instituts scientifiques, Jardins botaniques et zoologiques, Musées, Observatoires, Sociétés savantes. Published under the direction of Dr. R. de Montessus de Ballore. Pp. 2111. (Paris: Gauthier-Villars et Cie, 1923.) 35*s*.

WE welcome the appearance of the third (1922–23) issue of a work which, pending the issue of "Minerva" in its old form, is the only comprehensive directory of the learned world. Its scope is shown by the following analysis of its 2111 pages: (1) Directories of universities, colleges, and professional schools grouped by countries, 913 pages; (2) astronomical observatories, 86 pages; (3) libraries and archives, 325 pages; (4) museums and scientific institutes, 100 pages; (5) learned societies and academies, 194 pages; (6) list of *savants* who desire to exchange original dissertations with their fellow-workers, 7 pages; (7) index of names (more than 40,000), 428 pages; (8) other indexes and vocabularies, 53 pages. In part (1), in addition to the names of professors, lecturers, and other teachers and their subjects, are mentioned the principal administrative officers and, in many cases, the date of foundation, the total number of students, and the total annual expenditure; in part (2), publications, principal instruments, and programme of work; in part (3), days and hours of admission and annual holidays, date of foundation, special features, number of volumes, MSS., etc., annual budget, catalogues, rules for borrowers, name of librarian; in part (4), similar particulars with general description of exhibits or plant and mention of publications; in part (5), objects and aims, number of members, date of foundation, names of president and secretary, subscription, particulars of meetings, lists of fellows and of foreign members of some of the more important societies, and details of publications.

The editing of such an enormous mass of data is a formidable task and Prof. R. de Montessus de Ballore, the distinguished scholar who has had the courage to undertake it and the energy and perseverance to complete it, has thereby earned the gratitude of *savants* of all countries. The editor, who states that his object has been to achieve "the utmost clearness for refer-

ence," is to be congratulated on his judicious selection of type and on the ingenious device whereby he refers in the index of names not only to the page but to the particular section of the page in which the name sought is to be found.

The most generally useful part of the book, on the merits of which it will be judged, is part (1), and we have therefore examined some of the entries in this part, selected at random, in order to test its general accuracy. In such a work absolute accuracy is unattainable, but the editor, aiming at a high standard, "thought it better not to publish any information except such as has been directly communicated by administrative chief officials. . . . He has further had the proof of each entry corrected by its contributor." He has branded with an asterisk the rather numerous institutions which have failed to reply to his questionnaires in time and has reproduced the notices of them which appeared in the 1920–21 issue: thirty-one institutions which have not replied since 1919 have been excluded altogether. This procedure unfortunately has not prevented what we cannot but regard as an excessive percentage of error in the entries tested.

We venture to offer a suggestion regarding the entries in part (1) relating to institutions in the British Empire —about one-third of the total number. It is that the editor might use as the basis of such entries the Year-book issued by the Universities Bureau of the British Empire. Had he done so he would not have omitted such important institutions as the Osmania University of Hyderabad, Deccan, the University of Rangoon, the University of Patna (except for casual references), and University College, Swansea, his entries would have been more rather than less up-to-date, he would have saved himself a great deal of labour and expense, and would have been saved from such "howlers" as *His Grace* Eamon de Valera (Chancellor of the N.U.I.) and showing (and indexing) Petro Drilling as the name of a teacher instead of showing it as a subject (petroleum well-boring).

There is, moreover, another and a very important side to the question. If our university administrative officials, after having supplied returns to their own Universities Bureau and to Government Departments, are to be plied with requests for the self-same information in different forms for international Indexes and the League of Nations (which now proposes itself to compile something of the kind), it will not be surprising if some of the answers are short or if the pages of the Index become even more abundantly starred than at present. If the universities of each country would combine to produce a national yearbook, these would make the best possible material for (if not constituent parts of) an Index Generalis. For the British Empire the work is already done. Italy has her "Annuario degli Istituti Scientifici"—not yet appearing annually, however. The American Council on Education is, in its recently formed Division of College and University Personnel, acquiring much of the requisite material for such a yearbook, and Switzerland and the Netherlands have similar inter-university organisations.

The Cactus Family.

The Cactaceae: Descriptions and Illustrations of Plants of the Cactus family. By N. L. Britton and J. N. Rose. Vol. 3, pp. vii + 255, with 24 plates. (Washington: Carnegie Institution, 1922.)

ALL who grow Cacti will be glad to learn that the third volume of this fine work has been issued. It will probably appeal to a larger number of Cactus fanciers than the two preceding volumes, because it treats chiefly of the smaller kinds, which are more generally cultivated than the columnar or climbing species. This volume is of the same high standard of excellence as the two others, and as an account was given in NATURE of July 7, 1921 (vol. 107, p. 580) of the general character, scope, and details of the work, it will be unnecessary to repeat them here.

The subtribes dealt with in this volume are the Echinocereanæ, consisting of 6 genera (3 of them new) and 115 species, the largest genera being Echinocereus, 60 species, and Echinopsis, 28 species. The Echinocactanæ consist of 28 genera (18 of them new) and 166 species, the largest genera being Ferocactus, 30 species, Malacocarpus, 29 species, Gymnocalycium, 23 species, and Echinofossulocactus, 22 species. The Cactanæ consist of the two genera Discocactus, 7 species, and Cactus (better known as Melocactus), 18 species. Altogether 36 genera (of which 17 are monotypic and 21 are new) and 306 species are described, and well illustrated by 250 figures in the text, and 24 plates, most of them coloured.

Most of the Echinocactanæ are known to cultivators as belonging to the genus Echinocactus, and they will perhaps find it difficult to understand why, in this volume, only 9 species are placed under that genus, and all the others relegated to other genera. The reason is that while the vegetative characters of a large number of species is similar in type, the structural details of their flowers differ, and these floral differences have, in this work, been utilised for generic distinction in a manner not practised before. All this is made manifest in the keys, which are concise and clear, so that with the aid of the very numerous illustrations few should find difficulty in referring an unnamed species of the group to its proper genus.

It is much to be deplored that such a cumbersome sentence-like name as "Echinofossulocactus" should have been brought into use, but unfortunately there seems no valid reason for its rejection, for although it has been overlooked, it was proposed and characterised 81 years ago. It would, however, be of benefit to horticulturists and botanists alike, if, at the next Botanical Congress, a law could be made to prohibit the formation of such atrocious names in future.

The charming coloured plates give a good idea of the beauty of the flowers of these prickly plants, and the views showing some of them as they grow wild will convey to the mind of the cultivator the appearance they should have when well cultivated. Of the plants figured, *Ferocactus rectispinus* is one of the most striking on account of the formidable aspect it presents by its stout straight spines about 4 inches long. Of all the flowers figured the most remarkable is that of *Denmosa rhodacantha* (better known as *Echinopsis rhodacantha*), which is curved in a sigmoid manner, and has the petals closed tightly around the exserted stamens and style, quite unlike that of any other genus.

The well-known spineless *Echinocactus Williamsii* is rightly removed from that genus and now forms a monotypic genus under the name of *Lophophora Williamsii*. This plant has remarkable narcotic properties and has long been used by certain tribes of North American Indians in some of their ceremonies. One peculiarity of this plant is that its stamens are irritable, and when touched at the basal part they rapidly close in around the style, dusting their pollen upon the insect or other thing that touched them; an evident means of securing cross-fertilisation. A very full index completes the volume. There remain to complete the work the subtribes to which the genera Mammillaria and Rhipsalis belong. N. E. BROWN.

Our Bookshelf.

Kinematograph Studio Technique. (Technical Primers.) By L. C. Macbean. Pp. xii+111. (London: Sir Isaac Pitman and Sons, Ltd., 1922.) 2*s.* 6*d.* net.

ACCORDING to the subtitle of this little book, it is "a practical outline of the artistic and technical work in the production of film plays for producers, cameramen, artistes, and others engaged in or desirous of entering the kinematograph industry." There are chapters on production, the camera and its lenses, studio lighting and outdoor work, dark-room procedure, and so on. No previous knowledge of the subject is assumed, and many will be interested to learn of the artifices by which some of the more striking film scenes are produced, while they may also be surprised at the amount of painstaking labour and attention to detail which goes to the making of a successful film.

The Chemistry of Dental Materials. By Prof. C. S. Gibson. Pp. 176. (London: Benn Bros., Ltd., 1922.) 12*s.* 6*d.* net.

A CAREFULLY selected area in chemistry, largely metallurgy, is dealt with in this treatise, but what is done appears thorough. The treatment is not narrow and utilitarian, but as scientific as is possible. The second half of the book deals with miscellaneous materials used in dentistry, such as porcelain, cements, abrasive materials and antiseptics, and in this, of course, much information is given which cannot be found in the ordinary text-books of chemistry. The Brunner-Mond process for zinc, described on p. 100, is said to be now obsolete, and the same applies to the third form of tin (p. 105). Some mention of modern processes for lead extraction might have been given. Davy's name is incorrectly given on p. 146.

(1) *Installations électriques industrielles: Installation —Entretien—Contrôle.* Par R. Cabaud. (Bibliothèque Professionnelle.) Pp. 333. (Paris: J. B. Baillière et fils, 1922.) 10 francs net.

(2) *Alternating Current Electrical Engineering.* By P. Kemp. Second edition. Pp. xi+515. (London: Macmillan and Co., Ltd., 1922.) 17*s.* net.

(1) THE first part of M. Cabaud's book deals in a general way with electric installations for light and power. The numerical examples given will be helpful to the practical engineer. The maintenance of an installation is discussed in the second part, and in the third part methods of control are described. Various methods of penalising consumers who take their supply at a low-power factor are given.

(2) The principal changes in the new edition of Mr. Kemp's book are a new chapter on the protection of alternating current systems, and a number of alterations in the chapters on instruments.

The Radio Amateur's Hand Book. By A. F. Collins. Pp. xix+329+8 plates. (London, Calcutta, and Sydney: G. G. Harrap and Co., Ltd., 1922.) 7*s.* 6*d.* net.

A POPULAR description of radio communication which will be helpful to amateurs is given in this book. The author uses the proper technical terms, so any one who has read this book will be in a position to benefit by more advanced treatises on the subject. In the glossary, however, the attempt to define highly technical terms in the simplest language is of doubtful utility. Capacity is defined as "any object that will retain a charge of electricity." The book concludes with a long list of radio "don'ts," which will prove instructive to the beginner.

The Pupils' Class-book of Geography: the Americas. By Ed. J. S. Lay. Pp. 176. (London: Macmillan and Co., Ltd., 1922.) 1*s.* 3*d.*

IT is not easy to write an elementary text-book on geography which has any interest for the pupils who use it and at the same time is truly geographical, but Mr. Lay appears to have succeeded. His book is accurate, readable, and well illustrated by excellent black and white maps, and presents the essential features of the geography of the Americas.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Nature of the Liquid State.

IN his recent lecture to the Chemical Society on "The Significance of Crystal Structure," Sir William Bragg has described and discussed the extremely important results obtained in his laboratory by the X-ray analysis of various carbon compounds, notably those belonging to the aromatic series. The special feature brought to light by the investigations is that the ultimate unit of crystal structure or elementary parallelepiped is not the chemical molecule, but, generally speaking, is a complex formed by the union of two, three, or four molecules. Further, the symmetry of the crystal tends to increase with the number of molecules in the unit, and also with the symmetry of the molecule itself. In fact, there are simple quantitative rules, first stated by Shearer, connecting these quantities.

The question naturally arises whether when a crystal is melted and passes into the liquid state, the units in the latter condition are the same as in the crystal, or whether these break up further into the individual molecules. A method of investigating this very fundamental point is furnished by studies on the molecular scattering of light. If the units in the liquid state are the chemical molecules, that is, the same as in the condition of vapour, there should be a simple quantitative relation between the amount of *unpolarised light* (due to optical anisotropy) scattered by equal volumes of liquid and vapour and the densities in the two states of aggregation. This relation was indicated in my letter in NATURE of July 1, 1922, but the method of calculation there given has to be amended to make allowance for the fact that the electric polarisation within a fluid is, according to the Lorentz-Mosotti formula, greater than in free space. When this correction is made, it is found that the amount of *unpolarised* light actually scattered is considerably smaller than that indicated by the calculation. The conclusion thus appears to be forced upon us that the ultimate unit in the liquid state is not the same as in the state of vapour. On the other hand, if we adopt the view that the ultimate unit is the same in the liquid state as in the crystalline state, a way is opened for a satisfactory explanation of the observed result. For, according to Shearer's rule, the symmetry of the unit is always greater than that of the molecule, and hence the amount of unpolarised light scattered by it should be diminished, as is actually observed.

A further consideration which suggests that the ultimate unit in the liquid state is the same as in the crystalline solid is the existence of those remarkable substances, known as liquid crystals, studied by Lehmann and others. If a liquid be conceived of as a collection of elementary crystal parallelepipeds which are ordinarily prevented from thermal agitation from forming regular arrays, it is easier to understand how in favourable circumstances, such arrays come into existence temporarily and as quickly disappear. This conception appears to fit in very well with the mathematical framework of the kinetic theory of liquid crystals recently developed by Oseen (Stockholm Academy, Handlingar, 1921).

The same conception also appears to furnish a satisfactory explanation of the tendency shown by many liquids to refuse crystallisation and to pass into a highly viscous or glassy condition when supercooled. We have only to suppose that the units gradually join up, but in an irregular way, and form an optically heterogeneous structure. This conception of the constitution of vitreous solids is supported by the results of an extensive series of observations on the scattering of light in optical glasses and in supercooled organic liquids carried out under the writer's direction.

Finally, it may be remarked that the conception suggested does not, so far as the writer can see, appear to be inconsistent with any other known facts regarding the physical properties of liquids.

C. V. RAMAN.

210 Bowbazaar Street,
Calcutta, India,
February 22.

PROF. RAMAN'S very interesting explanation of his observations on the scattering of light by liquids is not affected if a slight change is made in his suggestion as to the appearance of the crystal unit in the liquid phase.

The crystal unit is a parallelepiped of minimum volume, the corners of which are occupied by molecules alike in all respects, including orientation. The definition allows the unit to be delimited in an indefinite number of ways. It is improbable that any one of these occurs as the only kind of unit in the liquid. For Prof. Raman's purpose it is sufficient, I think, to suppose that association, when it occurs, is ordered, the molecules joining up as if they were beginning to build a crystal. Let us suppose, for example, that the crystal belongs to the monoclinic prismatic class, in which there are four types of molecular arrangement. Any molecule of one type possesses with any molecule of the other three types, a plane, a digonal axis, or a centre of symmetry, respectively.

Groups of mutually arranged molecules may well be expected to form under suitable conditions, but it is not likely that the group will always consist of four, or be put together the same way. The group could always, however, be incorporated into a complete crystal: possibly some redressing of the boundary might be required.

An ordered association or incipient crystallisation has been suggested by Astbury (Proc. Roy. Soc., 102, p. 527) as the cause of the variability of the optical activity of tartaric acid with the strength of solution. The Debye-Scherrer photographs of colloidal gold show that each particle is essentially an association of gold atoms in crystalline array. It is possible that on the surface there is disorder which affects the further growth of the particle.

The point is that whenever association takes place, it tends to do so in the ordered fashion of the appropriate crystal.

W. H. BRAGG.

The Wegener Hypothesis and the Great Pyramid.

IN the discussions on the Wegener hypothesis I have not yet seen an allusion to the direct evidence given by Flinders Petrie ("Pyramids and Temples of Gizeh," second edition, 1885, pp. 11 and 41) of a change in azimuth at Gizeh amounting to four or five minutes since the erection of the Great Pyramid.

Petrie's account of the high accuracy used in the construction of the pyramid seems to render quite impossible an error of 4′ in the laying down of a meridian line 700 feet long, from which other baselines were set off during 30 or 40 years. As my

brother, Lt.-Col. M. M. Bidder, pointed out to me, every annual class in the local school of engineers would, in its turn, verify the meridian line under the supervision of their instructors; yet the second pyramid has the same orientation ($5\frac{1}{2}'$ west of north) as the core-plane of the first pyramid.

There are five meridians deduced by Petrie (p. 41) from his measurements. Of these the lowest and highest values occur in the Great Pyramid, being $-3'\ 43''\pm6''$ for the casing sides and $-5'\ 49''\pm7''$ for the passage. The four of them representing the Great Pyramid core and passage, and the Second Pyramid casing and passage, are all covered by the value $-5'\ 33''\pm17''$. Petrie's conclusion (p. 11) is "that the original base was probably more accurate than 0·05 inch in length and 12″ in angle."

GEORGE P. BIDDER.

Cambridge, February 26.

THE undoubted trend of the pyramids at 4600 B.C. was about 5′ west of the present pole. Each of the data was probably set out afresh from polar observation, as that would be easier than transfer by measurement. The accuracy of work there to 12″ of angle is in keeping with the accuracy of later work, as of granite planes 20 square feet in area with only inch/160 error at 3300 B.C., or of weights in eighth century A.D. with variations all within grain/200. The cause of a change of axis of about 5″ per century might be due to ocean currents or to earth deformation.

W. M. F. PETRIE.

Science and Armaments.

DR. FRENCH'S reply (NATURE, February 10) to my letter in the issue of January 20 does not touch upon the essential idea which I desired to express. I did not raise the question of the dispensability or indispensability of armaments at the present moment: a question on which a great deal might be said, but one which, I think, is somewhat outside the province of NATURE. The very columns of this journal are, however, a witness to a very real international brotherhood between men of all lands who find a common interest in the study of natural science and in its ceaseless warfare for the knowledge and control of material things for the common good of humanity.

Taking the wider view, how can it be a *consolation* that, under the urge of apparent national expediency, men should be spending their time in devising new methods of warfare by the application of that knowledge and training which should be a blessing to mankind instead of a curse? The new weapon used against A by B is to-morrow directed by A against B. Moreover, these methods, the scientific cleverness and interest of which often provide a poor mask for their brutality, are directed, not against barbarism, but largely against those for whom we now profess friendship. Such a condition may be difficult to avoid, but the great danger is that we should treat it as natural and inevitable, and grow insensible to the shame of these things. Have we forgotten the folly of

"All valiant dust that builds on dust"?

In the time of Davy it seems clear that science was respected as a thing apart from war, and we are led to inquire the reason for the change. Has it not been the willingness of inventors to exploit their knowledge, and to allow themselves to be exploited by men who cared less than nothing for science and all that it really stands for? There was small patriotism in many transactions that might be recalled, for things were sold to the highest bidder.

My first letter was, in brief, a plea that we should treat our science as something rare and precious, belonging not to ourselves only but also to all nations. Whatever burdensome and unpleasant tasks it may fall to our national lot to perform, we shall not face them the less effectively because we keep some of our most cherished possessions free from the dust of conflict. Hence my comment on the proposed action at the Science Museum. L. C. MARTIN.

Hafnium and Titanium.

REFERRING to Sir Edward Thorpe's interesting letter on this subject in NATURE of February 24, I would point out that the Cornish village of "Manaccan" is in the parish of Manaccan, which adjoins the parish of St. Keverne. There is an error also in the spelling. "Menaccan" should be Manaccan, and so with the stream at "Lenarth," it should be Lanarth. Presumably, therefore, the Cornish mineral should have been called Manaccanite and not Menaccanite, and the "new element" from it should have been termed "manachin" and not "menachin."

The Cause of Anticyclones.

IN a letter to NATURE of December 23 (vol. 110, p. 845) Mr. W. H. Dines has raised certain questions connected with the cause of anticyclones. The chief observational facts to be explained are the features peculiar to *most* high pressures, namely, the warm troposphere, the high and cold stratosphere. But not all anticyclones are warm even from a height of 3 km. up to 8 km. Some are cold to considerable heights. The gradual rise of the coefficient of correlation between pressure and temperature at the same level as one proceeds from 0 to 4 km., and the comparative uniformity of the coefficient from 4 to 8 km., is in itself strong evidence that in our latitudes these first 4 km. are the theatre of changes of air more and more frequent as the surface is approached, and that in the regions above 4 km. the air is nearly always of one sort as regards its origin. Again, with regard to persistence, Hanslik pointed out that only the "warm" anticyclones are steady and slow moving; the "cold" ones move quickly. Further facts to be taken into account are, that the conception of an anticyclone as a region of great vertical stability and of fine bright weather appears to be correct as a rule only for the "warm" anticyclone. In the other type anything short of violent weather conditions may be experienced.

I have recently (Q. J. Roy. Met. Soc., January 1923) put forward some evidence in support of the view that the explanation of the temperature peculiarities of the high- and low-pressure systems of our latitudes is, to a large extent, contained in the Bjerknes theory of their origin. In particular, when a pocket is made in the polar front by the southward rush of a great patch of polar air and when the pocket is afterwards closed behind this patch by the equatorial current from the south-west, the result is the formation of an anticyclone with closed isobars. From an examination of a more or less continuous series of upper-air observations I endeavoured to show that in such cases the change in barometric pressure at a given spot in the British Isles was indeed brought about by the fact that a thickness $h+\delta h$ of polar air had replaced a thickness h of the equatorial current, and that the

upper layers of the equatorial current appeared to have been raised unchanged through the height δh. Provided that the polar air was not more than 2 or 3 km. in depth, anticyclones formed in this way would be "warm" anticyclones, and would possess the features associated with such. But there are almost certainly cases where the encroaching polar air extends right up to the base of the stratosphere, and these appear to have all the characteristics of the cold, rapidly-moving anticyclone. This cold air, passing as it does into latitudes warmer than those where it acquired the main features of its existing temperature distribution, is heated from the bottom upwards, and becomes sufficiently unstable to provide within itself moderate rain and much cloud, but probably not persistent heavy rain. (It seems likely also that anticyclones do reach us in which there is either no polar surface air or only a negligible amount. Their formation was probably a much more gradual though similar process, and took place in more southerly latitudes.)

Mr. Dines has referred to the difficulty of maintaining the polar air *in situ*. The patch of polar air with which we are dealing may be described as a roughly circular one of 1000 or more km. in diameter; in the case of a "warm" anticyclone we may limit its depth at the deepest part to 2 or 3 km.; in the case of a "cold" anticyclone the depth in the centre may include the whole thickness of the troposphere. It appears to be maintained *in situ, so far as it is maintained*, by the currents which produced it. But actually the motion of most "cold" anticyclones—*i.e.* those of the deep polar air—does strongly resemble that of the flat drop of mercury on the laboratory table.

This problem was dealt with hydrodynamically by Exner in 1918 (*Sitzungsber. Akad. Wiss.*, Wien IIa, 127, 1918, pp. 795-847). He assumed as the initial conditions the existence of a mass of cold dense air (at rest or in motion) covering a small portion of the earth's surface and surrounded on all sides and above by warmer, less dense air. Particular points made by him include—(1) that the rotation of the earth renders possible the maintenance (at a slight inclination to the horizon) of a definite fixed bounding surface between the cold and the warm air; (2) that if a long ridge of cold air divides into two ridges flowing apart like cold waves, then the square of the velocity of separation of these waves is proportional to the depth of the cold air and to the difference of density between the cold and the warm; (3) also that in such a case friction with the earth's surface results in a shallow cold film being left over the whole area traversed by the waves and in the consequent gradual reduction in the height of the waves.

There is another consideration which supports the view that an anticyclone is of complex structure, and that is the frequency with which the air above an "inversion" of temperature can be shown to be of different origin from that below. It has usually been said that the surface layers were being cooled by radiation, also that there was outflow of air in these layers, and that the upper air, descending and settling, was being warmed adiabatically. When, however, an attempt is made to apply numerical data, cases arise where the change of temperature at a given point in space appears to have taken place much more rapidly than can be provided for by the most favourable time scale of the assumed operating causes. But in particular it is difficult to see why these causes should lead rapidly to the formation of comparatively sharp discontinuities of temperature of the order of 10° F., and also how they can lead to other than a very unstable vertical distribution of temperature. It seems much simpler, being provided with air of about the appropriate temperatures to northward and southward respectively, to explain the formation of anticyclones and their temperature distribution by means of the horizontal motion and interaction of these "polar" and "equatorial" currents.

Wimbledon, S.W.19, March 8.

The Phantom Island of Mentone.

ON a fine dark night, looking towards the point of Mentone from the sea-front about the middle of the West Bay, the appearance is presented of a dark island rising out of the sea in the gap which separates the lights of Mentone from those of Bordighera, some ten miles distant. This "phantom island" appears to be about 200 feet high, and from its darkness one would imagine it to be thickly covered with vegetation, its sides rising steeply out of the water. It is directly opposite, and quite near the sea-front of Mentone, from which it is separated by a very narrow channel of water. It appears, in fact, to be quite close to Mentone.

The explanation of this curious optical illusion is comparatively simple. The lights of Mentone and those of Bordighera present the appearance of being ranged round a curved bay, and they throw their reflections on the water, but they are separated by the East Bay, which is not seen, and by a dark, unilluminated portion of the coast. The corresponding part of the sea is devoid of reflections, and the impression is produced of a dark obstacle breaking the continuity of the line of lights and of their reflections in the water. This effect has been seen by independent observers on several occasions.

Ball Hardness and Scleroscope Hardness.

IN the ball hardness test Meyer found that $L = ad^n$. By combining this relation with Brinell's formula $H = L/A$, it can be shown that the hardness number when the ball is immersed up to its diameter is $\frac{2a}{\pi}D^{n-2}$. This value has been called the "ultimate hardness" (H_u), and is independent of the initial condition of the metal with regard to cold work.

Several attempts have been made to obtain a relation between standard Brinell and scleroscope numbers. The results have been more or less unsatisfactory. If, however, values of H_u be plotted against the scleroscope numbers of metals in the annealed condition, the points lie on a smooth curve which is independent of the ball diameter. The following results have been obtained by the writer using balls of 1 mm. and 10 mm. diameter:

Sample.	a.	n.	H_u.	Scleroscope No.	Ball diam.
Tin	5·53	2·185	5·4	3·5	10 mm.
Zinc	24	2·21	25	11	
Steel A	74	2·288	91	27	
,, W	185	2·292	231	51	
,, 4	262	2·292	327	64	
,, 3	342	2·293	428	73	
Armco	94	2·164	60	21	1 mm.
Steel 2N	112	2·185	71	23	
,, A	150	2·247	96	27	
,, S90	264	2·298	168	41	
Manganese Steel	453	2·303	288	50	

These results are plotted in the diagram below (Fig. 1).

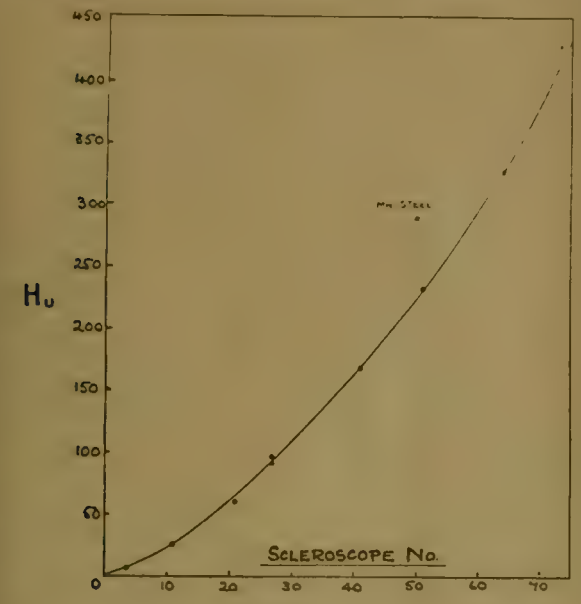

FIG. 1.

The relation between H_u and scleroscope number is quite good. The equation for the curve is:

$$H_u = 0{\cdot}79S^{1{\cdot}44}.$$

It is of interest that the ultimate hardness of manganese steel is higher than the scleroscope figure indicates.

If, as is believed, the value of H_u is independent of the ball diameter (D), then

$$kH_u = a_1 . D_1^{n_1-2} = a_2 . D_2^{n_2-2}.$$

k varies for different metals. Also, since with the 10 mm. ball

$$H_u = \frac{2a}{\pi} \times 10^{n-2},$$

then

$$0{\cdot}79S^{1{\cdot}44} = \frac{2a}{\pi} \times 10^{n-2},$$

$$S^{1{\cdot}44} = 0{\cdot}806a \times 10^{n-2}.$$

Metallic Crystals and Polarised Light.

DURING a research, not yet completed, on the optical properties of crystals, certain observations made in the case of metals appear to justify publication, from their importance in metallurgy.

If an etched metal specimen is examined under the microscope with the usual mode of illumination, but with plane-polarised light, and the reflected light is viewed through a "crossed" analyser, the different crystals in the field of view are sharply distinguished by differences of brightness. Rotation of the stage causes the brightest to grow dark and the darkest to light up, each crystal passing through four maxima and four minima in a complete revolution. The portions thus marked off often form parts of a crystal which appears of uniform structure under ordinary illumination; some structural difference which is indistinguishable, or with difficulty distinguishable without polarised light, produces marked differences with the crossed Nicol arrangement, which thus promises to be an effective new weapon in the metallurgist's armoury.

Curiously enough, these phenomena were observed quite independently by Miss Olwen Jones, who is engaged on the above-mentioned research in this laboratory, and by my colleague, Mr. C. Handford, of the Department of Metallurgy, who was working on a quite different problem. It was only on consulting him on the metallurgical aspects of the matter that I learned that he had noticed the effects a few days before. Her work suggests to Miss Jones that the cause may very possibly be a fine striated or laminated structure of the crystals, producing a sort of serration of their surfaces, the direction of the striation differing from crystal to crystal. When the vertical plane containing the serrations is parallel or perpendicular to the plane of polarisation in the incident beam the reflected light is plane-polarised, and is therefore extinguished by the analyser; when the angle between those planes is 45° or 135° the ellipticity, and therefore the brightness, is maximum.

Further investigations are being made both to test this theory and to develop the metallographic technique of the method. J. H. SHAXBY.

Viriamu Jones Physical Laboratory,
University College, Cardiff, March 12.

Easy Method of observing the Stark Effect.

IN the course of our investigations on the pole effect of the iron arc, we used a special device to keep the arc steady in the vertical position, and photographed the spectrum by means of a large quartz prism on a Littrow mounting. The lines originating in the electrode, extending from the visible part of the spectrum down to the ultra-violet, showed distinct separation, which was identical with the Stark effect observed with vacuum tubes. The separated lines show polarisations parallel and perpendicular to the field, which at the maximum amounts to about 20,000 volts per cm., and is confined to a very thin layer at the electrode, indicating a steep gradient. We found it convenient to work with a 500 volts arc, although the same phenomenon can be observed with a 100 volts arc. The effect is observed at the lower electrode, whether this be anode or cathode. Other metals can be used instead of iron.

The observation of the Stark effect is thus rendered extremely easy, as the only process involved is the production of a steady arc and the use of a spectroscope sufficiently powerful to resolve the lines into components. H. NAGAOKA.

Volcanic Dust and Climatic Change.

ON page 20 of his very interesting book, "The Evolution of Climate," Mr. C. E. P. Brooks says that I have "attributed glaciation to the presence of great quantities of volcanic dust in the atmosphere." This is too generous. I only insist that volcanic dust is one of the factors that control climate, and that at times it may (not must) have been an important factor, especially when mountains were high and continents extensive.

The Character and Cause of Earthquakes.[1]

By R. D. OLDHAM, F.R.S.

THE character of earthquakes, that is, of the disturbance which can be felt and causes damage, has long been established as a form of elastic wave motion, originated by some sudden disturbance in the substance of the earth. In some cases, such as the Japanese earthquake of 1891 or the Californian of 1906, the earthquake was accompanied by visible fractures and displacements of the solid rock, and where these have been observed it has also been noticed that the violence of the disturbance reached its maximum close by, and became less as the distance from the fracture increased. From this it is evident that, in such cases at least, the earthquake originated from the jar caused by sudden rupture of the rocks, and the fault, or fracture, may be regarded as the cause of the disturbance to which the earthquake was due. In many other cases, where no actual faulting or fracture is visible at the surface, and especially in earthquakes of moderate intensity and extent, a study of the observations makes it very probable that the immediate cause of the disturbance was a fresh movement along an old fault, or the formation of a new one, and so may be found in many text-books the statement, put forward and elaborated, that faults are the cause of those earthquakes classed as tectonic. Thus it might seem that the cause of earthquakes had been explained, but this is only the beginning of the story, for we need to know what causes the fracture which gives rise to the earthquake.

In pursuing this object, reference may be made to an earthquake which occurred more than a hundred years ago, at a time when the observation of earthquakes was in its infancy, and when little information of present value could be expected, had it not been for certain peculiarities in the country affected, and in the effect of the earthquake. Just beyond the north-western angle of the Indian Peninsula lies one of the most extraordinary regions of the world, known as the Runn of Cutch; more than 200 miles in length, and some 30 in width, it is a level barren plain, so flat and so near the sea-level that when the waters of the sea are heaped up, by the south-west monsoon, and the streams from the surrounding country come down in floods, the greater part of the surface is covered with a sheet of water, varying from a few inches to five or six feet in depth.

The whole of this region, however, has not always been so barren as at present, for, up to the seventeen hundreds, a large river, fed by the waters of the Punjab, and by overflow from the Indus, flowed down through Eastern Sind, across the Runn to the Kori creek, and on the banks of this river were fertile and populated tracts; also on this river was situated a frontier fort of the Government of Cutch, where customs duties were collected. Then, in the eighteenth century, through changes in the river courses far inland, the supply of water in this river began to fail, and a series of bunds, or what we would now call barrages, was built to hold up the water and divert it for irrigation. Towards the end of the century, the whole of the water supply was intercepted, and the region below relapsed into a state of desolation; but the fort of Sindri was still maintained, with a small garrison and a few officials to collect the dues, and so things continued until June 16, 1819, when the classic earthquake of Cutch occurred.

The fort of Sindri was not only ruined, but the ground on which it lay was also lowered in level, water flowed in from the sea, and the small garrison of Sindri saved themselves from drowning by taking refuge in the main tower, whence they were rescued by boat the next day. Nor was this subsidence the only change noticed, for, about four miles to the north, where before had been only a dead level plain, the survivors observed a long low mound, stretching east and west with a height of about 20 feet, along the northern edge of the flooded area. This mound, so like an artificial embankment, was immediately named the "Allah Bund" or "God's Barrage," on the same principle which named the bunds or barrages higher up the stream after the names of their makers.

FIG. 1.—Section across the Allah Bund and Sindri depression of June 16, 1819.

Ten years later, the ruins of the fort were seen still standing out of a waste of waters, and twenty-five years later, in 1844, a careful survey was made and levels taken, and this survey revealed a remarkable condition of things (Fig. 1). From the north the surface of the delta sloped southwards, at about eight to ten inches in the mile, to within six miles from the crest of the Allah Bund, when a reverse slope was met, and the surface gradually rose to nearly 20 feet above the level of the continuation of the southerly slope, or the level at which it presumably stood before the earthquake. Thence there was a steep slope downwards, to the water of the Sindri lake. On the south the original reports mention a depth of twelve feet of water close to the shore, immediately after the earthquake, and, as the original surface level must have been a few feet above that of the sea, we have a depression of some fifteen feet, which gradually died out in a distance of some six miles to the southward. From these facts it is clear that there was no appreciable change of level at a distance of about six miles on either side

[1] Condensation of a course of two lectures delivered at the Royal Institution on January 30, February 6.

of the line of the Allah Bund, but that along that line the ground on the north was upraised by some twenty feet and on the south depressed by some fifteen at the time of the earthquake.

The next earthquake to be considered is one which has been investigated with great care and in great detail; it is the Californian earthquake of April 18, 1906. In this there was a visible fracture, following what is known as the San Andreas fault, along which the shock attained its maximum intensity. This fracture was crossed at various points by roads and fences, and after the earthquake it was noticed that, where these crossed the line of fracture, they were no longer continuous, but the ends were shifted laterally by distances which varied at different places, but frequently amounted to twenty feet. This was not all, for the displacement was of a very curious nature, revealed by surveys of the displaced fences, and by a repetition of the original trigonometrical survey of the region. These showed that for a distance of some miles back from the fault line the stations had been displaced, those nearest to the line by the greatest amount, which lessened as the distance increased and, at about five miles or so to the east, became very small. Moreover, it was found that the movement on the eastern side of the fault had been to the southwards, and on the western towards the north.

Here we have a result very like that in Cutch; in both cases there was a well-defined line along which permanent change of position of the ground took place, simultaneously, in opposite directions on either side of the line of separation, and in both cases the displacement decreased in amount with increasing distance, till it ceased to be measurable at a distance of about half-a-dozen miles. The only difference was that in California the displacements were horizontal, with little or no change of level, while in Cutch they were vertical, whether accompanied or not by horizontal shifting cannot be known.

Paradoxical though it may seem, this movement on opposite sides of the fracture in opposite directions is quite in accord with known physical principles. If any block of material is compressed or stretched in one way, while free to expand or contract in a transverse direction, or if it is twisted by two opposite sides being forced in opposite directions, a complicated system of strain is set up, and if the strain is more than the material will bear, disruption will take place, on opposite sides of which the material will move in opposite directions.

Models to illustrate this principle have been constructed by others and myself, and from these considerations there has arisen what is known as the elastic rebound theory of earthquake origin, and as generally expressed this takes the form of a very slow growth of strain and a sudden release by fracture. The former, however, is by no means necessary, and the same result, as regards displacements of the ground, would be attained if the strain was rapidly, even suddenly, produced. There are, in fact, reasons for supposing that the growth of strain is not slow but rapid, yet the fracture and elastic rebound theory might be accepted as sufficient, if earthquakes could always be attributed to a single fracture, or to a close-set group of fractures; but in the case of great earthquakes, and sometimes of minor earthquakes also, the interpretation is put out of court by a study of the distribution of the intensity of the disturbance.

In illustration I may take first the great Indian earthquake of June 12, 1897, in which the central region of greatest intensity covered an area of about 140 miles long by 40 miles broad, over which there was a complicated series of faults, fractures, and distortion, which was certainly widely different from the comparatively simple origin generally assumed for earthquakes. This seemed at the time sufficient to account for all the facts, though there were some recorded as difficult to explain, and later examination seems to have established the conclusion that the origin of the earthquake cannot be limited even to this extensive area. In this earthquake only two of the isoseists could be plotted in detail, those of eight degrees and of two, or the extreme limit at which the shock could be felt; both exhibit considerable irregularities of outline, the most conspicuous of which is a pronounced projection to the westwards, and on the continuation of this line is a detached area, where the shock was again felt, after a gap where it was not felt. Col. Harböe has suggested, from a study of the recorded times, that there was an extension of the origin along this line, and though his plotting of the origin cannot be accepted in detail, I am convinced that, in the main, his conclusions are correct, for they very materially help to explain some peculiarities of the recorded observations, which remained inexplicable on the older and more generally used interpretation.

From this it appears that in earthquakes covering a large area we are not dealing with a simple disturbance, starting from an origin of restricted dimensions and propagated outwards, but with one of complex origin; and that in the outer regions of the seismic area the disturbance may be compounded of wave motion propagated from a more or less distant origin, where the initial severity was great, and of that coming from a nearer origin, of a lesser degree of severity, so that, instead of a fracture of at most a few tens of miles in length, we have to deal with a cobweb-like system of fractures, or something analogous, which may run to hundreds of miles.

The general drift of the argument I wish to set forth is probably best illustrated by the California earthquake of 1906. In this the greatest degree of violence was found along the line of the San Andreas fault, but the plotting of the isoseists shows that there was not only an independent centre in the San Joaquin valley, some forty miles to the eastwards, but also several independent centres of great intensity at lesser distances from the San Andreas fault. Moreover, the displacements recorded by trigonometrical survey make it probable that other similar independent centres would be found to the west, if the waters of the ocean had not made observation impossible. The records, therefore, indicate a set of separate centres of disturbance, scattered over a region of about three hundred miles in length by very possibly one hundred miles in width, and these separate centres, though independent as regards the surface shock, were all evidently connected with some common cause. Had they been the result of breakage under a slowly growing strain it is difficult to understand how so complicated, scattered, and extensive a

series of fractures could have originated simultaneously, but it is, to say the least, much less difficult to understand if the development of strain over the whole of the central area had been sudden, or at any rate rapid.

Then there is another point to be noticed, that in the central region the successive isoseists lie close together, while in the outer fringe they lie far apart; thus the distance separating the isoseists of ten and seven degrees, covering a range of three degrees of intensity, varies from 6 to 20 miles on either side of the San Andreas fault, while in the outer regions a similar range of three degrees covers from 120 to 250 miles. The close-set isoseists of the central region indicate a shallow origin, and such is proved by the San Andreas rifts, where the origin reached the surface of the ground; the widely set outer isoseists similarly indicate a deep-lying origin: and so we reach the conclusion that the earthquake origin was of a two-fold nature, the great violence in the central region being due to fractures and displacements close to, or at a comparatively shallow depth below, the surface, and that these fractures were the secondary result of a more deep-seated disturbance or bathyseism.

Having reached this conclusion there remain two questions of importance, what is the depth, and what is the nature of this bathyseism? As to the depth, the study of a remarkable, though only feeble, earthquake which affected northern Italy on August 7, 1895, has led me to conclude that the ultimate origin lay at 100 to 150 miles below the surface; but the best indications are to be had from the long-distance records of disturbances, which need not necessarily have been great earthquakes, in the ordinary sense of the words.

From these Dr. L. Pilgrim, in 1913, deduced the conclusion that the origin of the disturbance, in the case of the Californian earthquake, lay at a depth of about 100 miles, and, more recently, a similar method has been developed in this country by Prof. H. H. Turner, who has shown that the long-distance records indicate depths of origin ranging from fifty to three hundred miles below the surface of the earth. Now it seems fairly well established that earthquakes of quite shallow origin do not give rise to distant records, even when very violent in the place where they are felt, and it is probable that the disturbance recorded by these distant seismographs is not the superficial destructive earthquake, but the bathyseism.

Next comes the question of the nature of the bathyseism. That it must be in some way accompanied by a change in bulk of the material underlying the central area of the earthquake, seems clear, in some cases at least. Fracture such as is sufficient to explain most of the features of the surface shock seems out of the question, for the depths place it in the region of what it is nowadays the fashion to call the asthenosphere, that is, a part of the earth which is weak and plastic against stresses of long duration; but as regards change of bulk, recent researches have indicated one very likely mode in which it might be brought about. It is known that the foundation rocks of the outer crust are everywhere composed of an aggregate of crystalline minerals, the detailed study of which shows that the material must once have been in a condition analogous to that of fusion, from which it has solidified by cooling to its present condition. Further, it has been shown that the same original magma may crystallise out as quite different mineral aggregates, differing in density, and therefore in volume, by anything up to 20 per cent. The exact conditions which determine the passage from one form of chemical grouping to another are not known in detail, but it is probable that in each case there is some critical limit of temperature and pressure which determines it. If there were, in the interior of the earth, a mass of material near this critical limit, a small change of pressure or temperature might bring about a change of chemical combination, and with it a greater or lesser change of bulk, which, transmitted to the upper layers of the earth's crust, would give rise to displacements and distortion. Such changes might be unaccompanied by earthquakes, if they were slow and gradual, or, if rapid or sudden, might give rise to fractures in the surface rocks, of greater or lesser magnitude, and covering a larger or smaller area, according to the bulk of the deep-seated material undergoing a change of volume.

Without insisting on this as the nature of the bathyseism, and it is possible that other causes as yet unsuspected may also be at work, it is evident that we have an explanation which would suffice in the case of the larger, and of many of the smaller earthquakes. Yet there are some causes, perhaps no inconsiderable fraction of the total, in which the whole process leading up to the earthquake seems to lie quite close to the surface. To these, always small in extent, though sometimes of considerable severity, the consideration which I have outlined cannot at present be applied; in part they must be due to quite different causes, the consideration of which is not without interest, but this interest only arises after more extended and technical study than could be presented, even in outline.

Hydrogen Ion Concentration.

By Prof. A. V. HILL, F.R.S.

CERTAIN solutions are capable of conducting electricity, although their separate pure components are themselves incapable, or capable only to a slight degree, of so doing. This conductivity is attributed to the "ionisation" of the dissolved body, that is, to the splitting up of its molecule into two or more parts, some carrying a positive and others a negative charge, the resulting "ions" being capable of migration under an imposed electric field, and so giving to the solution the power of carrying a current. The electrically neutral molecule breaks up into (*a*) a negatively charged part, containing an excess of electrons which lend it its negative charge, and (*b*) a positive portion with a deficit of electrons, this deficit resulting in an equal positive charge. These positive and negative ions attract one another, as do all positive and negative charges, and are separable only if their mutual attraction be small enough to be overcome by the inter- and intra-molecular dynamic forces (not yet properly understood) tending to their separation.

The attraction between two charges is far greater if they be separated by some media than by others, to a

degree inversely proportional to the so-called specific inductive capacity of the medium. Water has one of the highest specific inductive capacities of all known substances, so that in it the attraction between two ions is relatively small: hence in water the ions may separate more effectively than in other solutions, and watery solutions are found to show the phenomena of electrolytic dissociation to an exceptional degree. Now water is a solvent of unique importance, partly because of its common occurrence, partly because it dissolves so many other bodies, and especially because, without exception, all biological phenomena occur in media which are essentially solutions or suspensions in water. Hence the study of the electrolytic dissociation of bodies dissolved in water is of quite peculiar interest, especially in physiology.

Now water itself is capable of electrolytic dissociation, though only to a small degree. In pure water at 22° C., eighteen parts in ten thousand million, that is, one ten-millionth part of one gram molecule per litre, is broken up into hydrogen ($H^{\cdot}$) and hydroxyl (OH') ions, the $^{\cdot}$ denoting the positive and the $'$ the negative charge. Such a very small degree of dissociation is of little importance in pure water: its insignificance is presumably due to the smallness of what we have called—to cover our ignorance—the dynamic forces tending to separate H_2O into $H^{\cdot}$ and OH'. In solutions, however, especially in solutions of acids and alkalies (that is, of bodies capable, by their own dissociation, of yielding one of the ions of water, $H^{\cdot}$ or OH'), even this small dissociation of water into its ions may become of preponderant importance.

It is obvious that the ions of the solvent itself, if present in appreciable amount, might be expected to play a special rôle in the behaviour of a solution: there is, however, a very real interest in the study of the hydrogen ion, in view of modern theories of the electrical constitution of matter. Atoms are supposed to possess a positive nucleus, with a charge equal to some multiple of the elementary negative charge on an electron, with layers of electrons circulating round the nucleus in stable orbits. The simplest atom of all is hydrogen, with a positive nucleus of unit elementary charge and a single negative electron revolving round it: remove this negative electron from a dissolved hydrogen atom, and we are left with a singly charged positive nucleus—next to the electron the simplest of all known natural bodies. In mobility, in combining power, in general dynamic effectiveness, this dissolved elementary unit might be expected to be, and actually proves to be, an agent of quite peculiar importance.

Expressing concentrations, in gram molecules (or ions) per litre, by means of brackets, it is found that at 22° C. in pure water,

$$[H^{\cdot}][OH'] = 10^{-14}.$$

This is the law of chemical mass action, which, in such a dilute solution as water is of its own ions, is accurately obeyed. Now in pure water there is no other agent capable of carrying electricity, and since the water itself cannot carry an appreciable resultant charge the positive and negative charges must balance one another, and therefore

$$[H^{\cdot}] = [OH'] = 10^{-7}.$$

If, however, we dissolve in the water another substance supplying one of the ions of water, for example, hydrochloric acid (HCl), which we may regard as being almost totally dissociated into its ions $H^{\cdot}$ and Cl', to a concentration (say) of one gram molecule per litre, then the equation above is entirely upset: the hydrogen ion concentration $[H^{\cdot}]$, or *c*.H as we shall often call it, has now become unity instead of 10^{-7}, so that the hydroxyl ion concentration $[OH']$ is now only 10^{-14}. Even this, expressed in actual molecules, is an astonishingly large number: there are about 6×10^{23} molecules in a gram molecule, so that even in normal hydrochloric acid there are six million hydroxyl ions per cubic centimetre. Clearly, even a strong solution of acid contains an appreciable number of hydroxyl ions.

If, conversely, we dissolve caustic soda to make a "normal" solution, instead of hydrochloric acid, then $[OH']$ becomes unity and $[H^{\cdot}]$ becomes 10^{-14}. We may make up different strengths of acids or alkalies in which the hydrogen and hydroxyl ion concentrations

Acid.	$[H^{\cdot}]$.	$[OH']$.	Alkali.	$[H^{\cdot}]$.	$[OH']$.
N	1	10^{-14}	N	10^{-14}	1
N/10	10^{-1}	10^{-13}	N/10	10^{-13}	10^{-1}
N/100	10^{-2}	10^{-12}	N/100	10^{-12}	10^{-2}
N/1000	10^{-3}	10^{-11}	N/1000	10^{-11}	10^{-3}
N/10000	10^{-4}	10^{-10}	N/10000	10^{-10}	10^{-4}

may be calculated as in the accompanying table. It is usual to consider only the hydrogen ion concentration: the hydroxyl ion concentration may always be calculated from it, by dividing the quantity k in the equation $[H^{\cdot}][OH'] = k$ by $[H^{\cdot}]$. At 22° C., $k = 10^{-14}$, but it varies slightly with temperature. Now $[H^{\cdot}]$, or *c*.H, may change enormously from one solution to another, say from 10^{-14} to 1, that is, one hundred million million times: hence it is impossible to represent the full possible range of variation of *c*.H in a single diagram, and since it is often necessary in physical chemistry to show the relations of *c*.H graphically, it has become customary to express the hydrogen ion concentration in terms of logarithms. The logarithm of 10^{-14} is -14, and of 1 is 0, so that log *c*.H can be represented, over almost the entire possible range, by numbers lying between 0 and -14. To avoid, further, the use of negative numbers the negative sign is understood, and the symbol *p*.H (or its variants P_H, P_h, etc.) is defined by the expression $p.H = -\log c.H$. In this way, at 22° C., if $p.H = 7$ the solution is neutral, if *p*.H be less than 7 the solution is acid, if *p*.H be greater than 7 the solution is alkaline; and a decrease of *p*.H means an increase in hydrogen ion concentration.

This system of nomenclature has certain obvious advantages if used with discretion: not seldom, however, it lends itself to obscuring the fact that the real agent at work is the actual hydrogen ion concentration *c*.H; it is difficult enough even for the expert to picture a quantity in terms of its negative logarithm, and it leads to confusion and suspicion on the part of the inexpert and beginner. For most of the phenomena of biology, moreover, which occur within a narrow range of *c*.H, it is quite unnecessary: for example, in physiology, apart from a few cases of secretion, the important range of *c*.H in the body is from 10^{-7} to 10^{-8}, and it is better when possible to deal with the hydrogen ion concentration in multiples (or decimals) of 10^{-7}, and to use the *p*.H notation only when the total range

considered is outside the limits of any reasonable diagram: occasions, in physiology, where this occurs will be comparatively rare.

The hydrogen ion concentration of a solution can be measured in a variety of ways: (*a*) by calculation from the laws of mass action, with a knowledge of the components of the solution and the proper constants; (*b*) by the use of a so-called hydrogen electrode: if a platinum wire, coated with platinum black and saturated with hydrogen gas, be dipped into a solution, it acts like a metallic electrode of pure hydrogen, and its electrode potential can be measured and made to give the *c*.H of the solution; (*c*) by the use of so-called "indicators," that is, dyes which change colour as the hydrogen ion concentration is altered, owing presumably to changes in their degree of electrolytic dissociation: the colour is used to measure the value of *c*.H. The study and measurement of the hydrogen ion concentration is becoming to-day almost a complete science in itself, and progress in physiology, and in some branches of colloid chemistry, still waits on further improvements in the accuracy and adaptability of its technique.

The importance of the hydrogen ion concentration in biology is bound up with the phenomena attending the dissociation of weak acids and of the so-called amphoteric electrolytes, and with the theory of "buffers." A weak acid, for example, carbonic acid H_2CO_3, is one which is only slightly dissociated into its ions: the reaction $H_2CO_3 \rightleftarrows H^{\cdot} + HCO'_3$ goes almost entirely $\leftarrow$: similarly with a weak base. The salt of a weak acid is a very effective regulator of the hydrogen ion concentration; it acts as a "buffer" to resist the effect of adding a strong acid. Let the salt of the weak acid be XY, dissociated into its ions $X^{\cdot}$ and Y'. Let us add to this a strong acid HZ, dissociated into $H^{\cdot}$ and Z': we might expect the *c*.H to be largely increased. In our solution now are all the ions $X^{\cdot}$, Y', $H^{\cdot}$, and Z': $H^{\cdot}$ and Y', however, cannot exist side by side in solution in appreciable amount, since (by hypothesis) the acid HY is a weak one, that is, the reaction $H^{\cdot} + Y' \rightleftarrows HY$ goes almost entirely $\rightarrow$. Hence the hydrogen ions are eliminated to form the undissociated weak acid HY, and we are left (i.) with the ions $X^{\cdot}$ and Z' of the salt XZ of the strong acid, and (ii.) with the undissociated weak acid HY.

The expected increases in *c*.H can, in this way, be reduced almost to an insignificant amount, and in physiology (where an exact constancy of *c*.H appears to be necessary for the maintenance of the normal physico-chemical structure and behaviour of the living cell) the presence of very effective "buffers" in every organ, tissue, and cell has been shown in recent years to be of ultimate importance. Phosphates, carbonates, and the salts of proteins, such as hæmoglobin, are the chemical agents by which this regulation is effected. In addition to these we have what we may call "living buffers," the cells of the respiratory centre and the kidney for example, which by their activity maintain, in an amazingly accurate manner, the constant *c*.H required in the "internal environment" of all the other cells of the body; that is, in the blood and tissue fluids which bathe them. In the body, the important buffers are those absorbing the effects of added acid, especially carbonic and lactic acids, which are produced with great rapidity and amount during muscular exercise. The salts of weak bases, however, are equally effective buffers, from the physico-chemical point of view, in their capacity of neutralising the effect of strong alkalies. Some bodies, moreover, the so-called "amphoteric electrolytes," of which amino acids and proteins are the most notable, are capable of functioning both as weak acids and as weak bases: hence their salts (for example, sodium "hæmoglobinate," or hæmoglobin chloride) may act, under suitable conditions, as buffers of either type.

The importance of the hydrogen ion concentration in physiology is almost certainly concerned—at least in part—with the electrical properties of the proteins which constitute the formed constituents of living cells. It may also be concerned with the processes of oxidation and reduction occurring in metabolism, but with these we will not deal further now. Proteins are complex compounds of amino acids, and each amino acid possesses the latent possibility of acting either as a weak base (in virtue of its $-NH_2$ group) or as a weak acid (by reason of its $-COOH$ group). Hence proteins are capable, at a suitable *c*.H, of forming salts at many and varied points in their enormous molecules. These salts are largely dissociated into their ions, so that the protein of the living cell may be regarded as a large electrified molecule, surrounded by a shell of attendant positive (or negative) ions.

The electrical phenomena accompanying any form of activity in a living tissue demonstrate the importance of this electrification of the fundamental chemical basis of protoplasm, and it is well known that the existence and properties of colloidal solutions are intimately dependent upon the electrical charges on the surfaces of the colloidal particles. Now the degree of dissociation of a weak acid HZ, into its ions $H^{\cdot}$ and Z', depends upon the hydrogen ion concentration: according to the laws of chemical mass action the ratio of the dissociated to the undissociated part is inversely proportional to *c*.H. Hence, if the protein be acting as a weak acid, the degree of electrification of the protein molecule will be decreased by an increase of *c*.H, and if the behaviour of a living cell depend upon the electrical characters of its protein constituents we should expect it to be largely modified by an appreciable change in *c*.H.

This actually occurs: the most violent and extensive physiological response is produced, both in single cells and in larger complex animals, by quite small changes in *c*.H, and all animals possess the power of reacting, in a sudden and vigorous manner, to any alteration in the *c*.H of the fluid immediately in contact with their cells, in such a sense that the change is diminished, or neutralised, and the physico-chemical characters of the protein molecules of their protoplasm are maintained in their normal state. We know, at present, very little about the molecular structure of living protoplasm: we cannot, however, be far wrong in supposing that the ionic and electrical phenomena displayed by the protein molecules which constitute it are among its most fundamental properties, and that these are modified, to a high degree, in accordance with purely physico-chemical laws, by the hydrogen ion concentration of the fluid in which it is suspended or dissolved.

Obituary.

DR. J. G. LEATHEM.

THE death of Dr. John Gaston Leathem on March 19, at the age of nearly fifty-two years, removes a scholar who was prominent in the world of Cambridge mathematics. Coming from Queen's College, Belfast, in 1891, he made his mark in the triposes of 1894 and 1895. He held the Isaac Newton studentship for astronomy and physical optics during the period 1896–99, soon gaining also a fellowship at St. John's College. His interests were then mainly in electrodynamic theory; and the work of his studentship produced a memoir (Phil. Trans., 1897, pp. 89-127), which ought to be classical, in which the theory of the magneto-optic rotation of light and the cognate reflection effect were finally systematised and coordinated, under the test of laborious comparisons with the numerical experimental data.

In due course Dr. Leathem became mathematical lecturer at St. John's College, and afterwards university lecturer: and for a series of years he exerted a wide influence on the teaching. For the mathematical tripos he was an examiner on as many as six occasions, two of them (1912, 1913) after he had been withdrawn from all teaching except an annual advanced course on electrodynamics. For he had become senior bursar of his college in 1908, and henceforth he threw himself into its external affairs and general administration with assiduity and practical success.

In 1905 Dr. Leathem took up the editorship, in conjunction with Prof. E. T. Whittaker, of a series of Mathematical Tracts projected by a Cambridge group of lecturers, which, in numerous volumes, has become under their care an important survey, almost an encyclopædia, of domains of recent higher mathematics. To this undertaking he contributed the earliest volume of the series, and one on optical systems. His own later special investigations, exhibiting the geometrical trend that is associated with the Irish school, thus including applications of conformal transformations to physical problems, were published mainly by the London Mathematical Society and the Royal Irish Academy. A note in Roy. Soc. Proc. established an unexpected mode of interaction between a magnet, supposed to consist of revolving electron-systems, and a varying electric field, too small, however, to permit of experimental scrutiny.

During the War Dr. Leathem felt bound to volunteer for work in the Research Department at Woolwich Arsenal, then in need of mathematical help, handing over as much of his bursarial work as was possible to senior colleagues. About two years ago he had to submit to a sudden and very drastic surgical operation: in time he recovered, and though never strong again, he resumed his activities with all the previous zeal and judgment. But the mischief could only be delayed, not removed: and his loss will now be deeply felt not only in his own college but also throughout the university. J. L.

DR. E. A. MERCK.

THE death took place at Darmstadt on February 25 of Privy Councillor Dr. E. A. Merck, senior partner of the chemical works of E. Merck. Dr. Merck was born at Darmstadt on July 30, 1855; he studied pharmacology and chemistry, and took his degree in Freiburg i. B. under Ad. Claus. He then took over the Engel-apotheke, which had been in the possession of the family of Merck since 1668, and became one of the managers of the chemical works of E. Merck.

The works, which were then on only a modest scale, were greatly enlarged through the energy and initiative of Dr. Merck and his cousin, Louis Merck, who was his partner, and developed into one of the greatest manufactories of preparations for medical purposes. To the production of drugs was added that of alkaloids, the preparation of synthetic remedies (for example, "veronal"), and various sera. In response to the demand of chemists for pure reagents, the production of chemically pure preparations and solutions for volumetric analysis was taken in hand, and the firm's products became famous throughout the world. The connexion between the industry of chemical preparations on one hand and the pharmaceutical chemists and physicians on the other was steadily maintained by the literary publications: "Mercks Jahresbericht," "Mercks Index," and "Mercks Reagenzienverzeichnis."

Dr. Merck took an important part in all these developments. At the same time he worked continually for the improvement of the training of pharmaceutical chemists and the social position of the whole chemical profession. For six successive years he was president of the Verein Deutscher Chemiker, and he represented German chemistry at many international gatherings. His strong historical interest led him to give particular attention to the work of Liebig, and he was one of the founders of the Liebig Museum at Giessen.

WE regret to announce the following deaths:

Prof. A. S. Dogiel, professor of histology in the University of Petrograd, whose investigations on the histology of the peripheral nervous system are well known.

Prof. A. S. Flint, emeritus astronomer of the Washburn Observatory, University of Wisconsin, on February 22, aged sixty-nine.

Prof. W. S. Haines, professor of chemistry, materia medica, and toxicology at Rush Medical College, and professor of toxicology in the University of Chicago, on January 27, aged seventy-two.

Sir Joseph M'Grath, a vice-president of the Royal Dublin Society, and registrar of the National University of Ireland since 1908, on March 15, aged sixty-four.

Mr. W. Pearson, for nearly fifty-eight years prosector to the Museum of the Royal College of Surgeons of England, on March 15, aged eighty-two.

Sir Thomas Roddick, formerly professor of surgery, McGill University, and the first Colonial president of the British Medical Association, at its Montreal meeting in 1897, on February 20, aged seventy-six.

Sir William Thorburn, emeritus professor of clinical surgery in the University of Manchester, on March 18, aged sixty-one.

Prof. J. Trowbridge, emeritus professor of physics at Harvard University, on February 18, aged seventy-nine.

Mr. E. W. Vredenburg, of the Geological Survey of India, on March 12.

Prof. N. E. Wedensky, professor of physiology in the University of Petrograd.

Current Topics and Events.

THE Conjoint Board of Scientific Societies was dissolved by a resolution passed at a meeting of the Board held at the Royal Society on March 22. The Royal Society took the initiative in the formation of the Board in 1916; and when a few months ago the council decided that the society no longer desired to remain in this federation, whether under the original constitution, or the new one proposed, there was little hope for the continued vitality of a body so sharply truncated. The chief scientific and technical societies—about sixty in all—in the British Isles were represented on the Board, and the special committees appointed from time to time have produced a number of notable reports. Among such committees may be mentioned those on the water power of the British Empire, glue and other adhesives, national instruction in technical optics, timber for aeroplane construction, and the application of science to agriculture. A couple of years ago the Board appointed a committee to arrange for the publication of a world-list of scientific serials, with indications of libraries in the chief centres of Great Britain where such periodicals could be consulted. It is gratifying to know that the interests of the Board in the list, towards the publication of which the Carnegie United Kingdom Trust made a grant of 1000*l.*, have been vested in three trustees, so that notwithstanding the dissolution of the Board the issue of the list is assured. For this provision thanks are due largely to Dr. P. Chalmers Mitchell. In its early years the Board owed much to Sir Joseph Thomson, who, as president of the Royal Society, was president also of it. Sir Arthur Schuster and Sir Herbert Jackson were associated with the Board throughout its existence, and did invaluable work for it, while the devoted service rendered by the Secretary, Prof. W. W. Watts, created a sense of indebtedness which can never be adequately expressed. It is impossible not to regret that a federation of such early promise should have had so short a life.

SIR FREDERICK MOTT, pathologist to the mental hospitals of the London County Council for twenty-seven years, and director of the Council's pathological laboratory, is retiring from the service at the end of this month. By his own researches and by stimulating and encouraging the spirit of investigation in others, he has brilliantly discharged the difficult task of establishing the tradition that it is the business of the authority having control over asylums for the insane, not only to see to the security and comfort of the inmates, but also to secure that progressive work on the nature and causes of mental diseases shall be directed towards their prevention and cure. His demonstration that general paralysis of the insane is in fact a late manifestation of syphilis in the nervous system is perhaps the most conspicuous piece of his personal work among patients and in the laboratory, and it has entirely altered our conception of the disease. The *Archives of Neurology* and other journals show the quantity of good work which came from the laboratory at Claybury—the more remarkable when we remember that Sir Frederick was also a busy general physician attached to Charing Cross Hospital. Two of the plans in which he was much interested have now matured in the moving of the central laboratory to a more accessible site in London, and in the establishment of the Maudsley Hospital at Denmark Hill for the study of the early stages of mental derangement. The solid foundation which he has laid should do much to secure success for the new arrangements.

AMONG the important centenaries of scientific interest this year is that of the birth of Sir William Siemens, who was born in Lenthe, Hanover, on April 4, 1823, and died in this country on November 19, 1883. Siemens took up his residence in England in 1844, and from 1859 was a naturalised Englishman. It would be difficult to measure the value of his services to our industries, for he was one of the foremost electrical engineers of his day, while as a metallurgist his name is connected with the introduction of the regenerative furnace and the manufacture of open-hearth steel. His scientific knowledge was no less noteworthy than his inventive ingenuity, while above all he was a man of affairs. The first president of the Society of Telegraph Engineers, he also served as president of the Mechanical Engineers and of the Iron and Steel Institute. It was in his address to the latter body that he threw out the pregnant suggestion of utilising some of the power of the Niagara Falls and transmitting it long distances by electric conductors. In much of his work he was associated with his brothers Werner, Carl, and Friedrich. In the issue of NATURE for November 29, 1883, Lord Kelvin gave an account of Siemens's scientific career and work as a contribution to our series of Scientific Worthies.

ON April 7 occurs the centenary of the death of the French physicist Jacques Alexandré Cesar Charles, the pioneer of scientific ballooning. Born in 1746, Charles began life as a clerk in the Ministry of Finance. He devoted his leisure to scientific pursuits and he became known as a lecturer and experimenter. In 1783, a few months after the brothers Montgolfier had made their first experiments with the hot-air balloon, Charles conceived the idea of filling a balloon with hydrogen. His first important demonstration was made in December 1, 1783, when Charles and his companion, Francis Robert, rose from the gardens of the Tuileries to a height of 9000 feet. Charles made his hydrogen by the action of iron on sulphuric acid. To him is due the invention of the valve, the car, the use of ballast, and the employment of rubber for rendering the silken envelope gas-tight. He was also the first to use the barometer in a balloon. Very great interest was excited by the work of Montgolfier and Charles, and Lavoisier was instructed by the Paris Academy of Sciences to draw up a report as to the value of the discovery. Charles was admitted to the Academy

in 1785, received a pension from Louis XVI., and, after the Revolution, occupied a post at the Conservatoire des Arts et Métiers. He is buried in the Père-Lachaise cemetery.

THANKS to the generosity of the Spanish Government the Science Museum, South Kensington, now possesses a model of the flagship of Columbus, the *Santa Maria*, in which, accompanied by the *Pinta* and *Nina*, he made his famous voyage of discovery in 1492. The model is a copy of one in the Naval Museum, Madrid, and has been made under the supervision of the director, Capt. Don Antonio de la Reyna y Pidal. From time to time many inquiries have been made regarding the details of the *Santa Maria*, and for the Chicago Exhibition of 1893 a replica was constructed and sailed across the Atlantic by a Spanish crew under Capt. Concas, the course followed being that travelled by Columbus. The *Pinta* and *Nina* were small vessels of about 40 or 50 tons, but the *Santa Maria* had a displacement of 233 tons. She was 95 feet long over all, carried a complement of 52 men, and mounted eight guns for firing stone shot. Another of the existing models of the *Santa Maria* is that made by Capt. Terry, who searched Southern Europe for information; this model is illustrated in Chatterton's well-known "Sailing Ships and their Story."

MR. STANLEY BALDWIN, Chancellor of the Exchequer, announced in the House of Commons on March 22 that he had decided to withdraw the proposal to charge fees for admission to the British Museum, Bloomsbury, and the Natural History Museum. The announcement followed a statement by Major Boyd-Carpenter, Parliamentary Secretary to the Ministry of Labour, that the cost of equipping the British Museum and the Natural History Museum with turnstiles for the collection of admission fees had been estimated at £500, and that possibly one extra attendant would be required.

A CONVENTIONAL distinction is often drawn between science and art, but in their finest developments they have much in common. In an address before the Circle of Scientific, Technical, and Trade Journalists on March 20, Prof. Beresford Pite defined the artist as one who found his pleasure in his work—a definition that surely applies equally well to the researcher in pure science. He also pointed out that the full development of architecture requires the stimulus of contact with other countries. The Elizabethan period was one of poverty in architectural effort, though literature flourished, a condition attributed to the isolation of this country from the Continent, owing to religious differences. This again applies to science, for the crippling effect of lack of intercourse with men of science in other countries is well recognised. Perhaps a third point of similarity might be found in his claim that the architect, like the man of science, does much work without prospect of reward. He is not paid for what he "rubs out," neither is the experimenter proportionately rewarded for the many fruitless experiments that usually precede a genuine discovery. In the course of the discussion the Press, the influence of which in directing public attention to the claims of science has already been invited at previous meetings, was given an opportunity of hearing a masterly lecture on the ideals of architecture.

THE annual meeting of the National Institute of Industrial Psychology was held on March 20 at the rooms of the Royal Society. Mr. H. J. Welch, chairman of the Institute, presided. Lord Balfour was the principal speaker, and he pointed out how mistaken is the idea that science has nothing to do with practical life. As a nation we are too apt to think that science exists for men of science, and that it can have no interest for practical men. He wished to bring together men of science, capitalists, leaders of labour—all the forces of society—in order to further the work of uniting science and practice. By the application of physiology and psychology Lord Balfour expressed the hope that the labours of the wage-earners may be made easier and smoother, so that work, instead of being a kind of torture, may become a pleasure. He quoted Francis Bacon to the effect that the object of science is the relief of man's estate. The next speaker, Sir Charles Sherrington, president of the Royal Society, described the changes which have taken place during his lifetime in the position of psychology. The early pioneers in experimental psychology occupied themselves with problems which seemed quite remote from any practical application; now, many of these early researches are recognised as of far-reaching practical importance. Sir Charles made a special plea for adequate support for, and sympathy with, that part of the work of the Institute which is known as vocational selection. Most boys have no chance whatever of getting into an occupation that suits them best; unguided, they drift into any trade. Both Sir Lynden Macassey and Mr. A. Pugh showed from different points of view that there is more waste in industry owing to indifferent management than to indifferent workmanship. Industrial managers are more equipped, as a rule, for controlling machines than for controlling men. Dr. C. Myers, director of the Institute, gave some details of the actual work of the Institute.

THE Central Mining-Rand Mines premium of 25*l.* has been awarded by the South African Institution of Engineers to Mr. W. J. Horne, organiser of technical education, Transvaal, for his paper on "Technical Education for Trades," read at Johannesburg.

AT the ordinary scientific meeting of the Chemical Society held on March 1, Prof. Bohuslav Brauner, Prof. Ernst Cohen, Prof. Gilbert N. Lewis, Prof. Charles Moureu, Prof. Amé Pictet, and Prof. Theodor Svedberg were elected honorary fellows.

THE King and Queen have consented to lay the foundation-stones of the new buildings for medical research at University College Hospital, London. These buildings, it will be remembered, have been made possible by a munificent gift of 1,250,000*l.* from the Rockefeller Foundation, announced some three years ago. It is probable that the ceremony will take place towards the end of May.

THE annual general meeting of the Society of Chemical Industry will be held at Cambridge on June 21–23. Dr. E. F. Armstrong will deliver his presidential address on the first day of the meeting. On June 22, the Society's medal will be presented to Dr. C. C. Carpenter, and later in the same day Dr. F. W. Aston will deliver an address on "Isotopes." During the early part of the same week, it will be remembered, the International Union of Pure and Applied Chemistry is also meeting at Cambridge.

AT the annual general meeting of the Chemical Society, held on March 22, Sir James Walker, the retiring president, delivered his presidential address entitled "Symbols and Formulæ." The following elections were afterwards declared: Prof. W. P. Wynne as president; Prof. J. F. Thorpe as treasurer; new vice-presidents, Dr. J. T. Hewitt, Prof. G. T. Morgan, Sir William J. Pope, Prof. J. M. Thomson, and Sir James Walker; new members of council, Dr. E. F. Armstrong, Prof. W. N. Haworth, Dr. C. K. Ingold, Dr. H. McCombie, Dr. G. W. Monier-Williams, and Dr. J. Reilly.

IN Great Britain the period of Summer Time will begin this year at 2 A.M., G.M.T., on Sunday, April 22, and will continue until 2 A.M., G.M.T., on Sunday, September 16. In Belgium, Summer Time begins after midnight on March 31. The Paris correspondent of the *Times* states that, in order to meet the opposition to Summer Time from representatives of agriculture in the Chamber of Deputies, the French Government has decided to substitute for it the time of Strasbourg, which is about thirty-five minutes in advance of Greenwich time.

WITH reference to the letter published in NATURE of February 17, p. 222, describing a remarkable mirage observed at Cape Wrath on December 5, 1922, a letter has been received from Mr. Albert Tarn of Thornton Heath, who describes a somewhat similar occurrence at Oban in August 1885. Mr. Tarn states that he was sleeping in a bedroom at the back of a house adjoining the Waverley Hotel, so that the room faced inland. During the course of the night he awoke, and on looking out of the window saw what appeared to be a view of Oban Bay with the moon shining on the water. The date is not given, and no observations are available to decide whether the circumstances resembled those at Cape Wrath.

THE report of the National Museum of Wales for 1921–22 announces the completion of the western section of the new building and of the western portion of the entrance-hall. A fumigating chamber has been installed to rid specimens of insects and other pests. Among the many interesting accessions we note a beaker of early Bronze Age type from Glamorganshire, which contained the remains of a child's skull showing symptoms of rickets, the earliest recorded instance of this disease in Great Britain or perhaps in the world. Several thousand specimens of fossil plants most carefully collected from the successive beds in the Coal Measures of Gilfach Coch and Clydach Vale by Mr. David Davies, and the basis of his recent paper before the Geological Society, have been presented by him and will be preserved in cabinets given for the purpose by local bodies interested in the coal industry.

THE Australian National Research Council has commenced the publication at Sydney of a quarterly journal under the editorship of Dr. A. B. Walkom, which is to give short abstracts of papers written by Australian scientific workers—even when they appear in periodicals not published in Australia. The price of the journal is 4*s*. per annum. The first four numbers of the journal have already appeared, and extend to 32 pages. The abstracts are arranged in sections according to the branches of science represented on the Research Council, and the 245 which constitute the first year's total are distributed among the sections as follows: agriculture 70, botany 31, chemistry 14, engineering 1, geography 1, geology 18, mathematics 1, mining and metallurgy 0, pathology 13, physics 1, physiology 4, veterinary science 3, zoology 88. Cross references are given so that an abstract of interest in a section other than that in which it appears can readily be found. The distribution of the abstracts among the sections is interesting as evidence of the extent to which science is being brought to bear on the special problems which a developing colony presents to its Government.

MR. J. REID MOIR is publishing through Mr. W. E. Harrison, the Ancient House, Ipswich, under the title of "The Great Flint Implements of Cromer, Norfolk," an account of his discoveries in 1921 of a large and remarkable series of flint implements and flakes, to which attention has already been directed in the columns of NATURE. The forthcoming volume will contain a number of illustrations by E. T. Lingwood.

WE have received from Messrs. Watson and Sons Parker Street, Kingsway, Bulletin 50.S., containing descriptions of some new X-ray accessories. A new mercury interrupter with a rotary rectifier designed for continuous work under heavy loads is illustrated, also an automatic time-switch for exposures ranging from one-sixteenth of a second to thirty seconds. The extensive use of X-rays for therapeutic purposes has led to great improvements in the design of suitable stands which serve the double purpose of holding the X-ray tube and allowing it to be manipulated at any angle. The new stand illustrated here has some good constructional features, and the tube itself is almost completely enclosed by protective material which has an absorption equivalent of 3 mm. of lead. This protective shield is provided with an arrangement which permits of forced air cooling during the working of the tube.

THE 1922 Year-Book of the Franklin Institute, Philadelphia, contains some interesting facts from the history of the Institute. It was organised in 1824 for "the discovery of physical and natural laws and their application to increase the well-being and comfort of mankind," and duly installed in its own house

two years later. It is noteworthy that in 1831 a joint committee of the Institute and the American Philosophical Society began systematic meteorological observations in aid of agricultural and other interests, and eight years later the Pennsylvania legislature made a grant of 4000 dollars for the purchase of instruments at the discretion of the Institute; this is stated to be the earliest instance on record of the appropriation, in any country, of public funds for the collection of facts relating to the weather. The Institute awards medals, of which the best known is the Franklin medal, for distinguished work in advancing physical science or its applications; it was founded in 1914, and among its recipients have been Sir James Dewar and Sir J. J. Thomson. Other awards made are: the Elliott Cresson medal, for research and invention; the Howard N. Potts medal, for distinguished work in science or the arts and for papers presented to the Institute; the Edward Longstreth medal, for meritorious work in science or the arts; and the Boyden premium of 1000 dollars, to any resident of N. America who shall determine by experiment whether all rays of light and other physical rays are or are not transmitted with the same velocity; an award was made in 1907 for a solution dealing with the visible and ultra-violet parts of the spectrum.

Our Astronomical Column.

METEORS IN APRIL.—Meteors are seldom abundant in April, but there are a number of interesting showers visible, including the Lyrids, which are connected with the first comet of 1861. This display usually attains a maximum on April 21, and the conditions will be rather favourable this year, as the moon will be visible only as a crescent in the evening sky. The Lyrids exhibit a radiant which moves eastwards about 1 degree per day, and we require more evidence on this point. The shower, however, is of very short duration in its active stage, and meteors belonging to it are rarely seen two or three days before or after the date of maximum.

In April there are a large number of feeble showers which it is desirable to investigate further. These include positions near α Persei, β Ursæ Majoris, α Cygni, ε Cephei, etc. In Hercules, Corona, Boötes, and Ophiuchus there are a few well-pronounced displays which apparently recur annually.

THE ECLIPSE OF SEPTEMBER 1922 IN QUEENSLAND.—Mr. J. C. Russell, of Brisbane, sends some notes on his observations of this eclipse made at Stanthorpe, a favourite summer resort, nearly 3000 feet above sea-level. The N.S.W. Branch of the B.A.A. were also stationed here. There was an extensive view over the plain to the west, and the moon's shadow was seen approaching, a little in front of the horizon line, and therefore about 10 miles distant, looking like a local rain squall. Shadow bands were observed at the same time. The central dark bands were 12 or 15 inches apart, about 4 inches wide, fringed with an equal width of half-tone on each side, and a bright strip between them. They passed at the rate of 10 per second. Their least distance from his eye was 8 feet. They were followed to a distance of 30 or 50 feet, where they appeared fainter but 3 or 5 times wider than when nearest. He ascribes them to compressional waves in the air caused by the cooling effect of the shadow cone, which was passing at a rate exceeding that of sound. Mr. Russell also makes the plausible suggestion that the shapes of the bands as seen are largely modified by the phenomenon of persistence of vision. He thinks the apparent enlargement at a distance was a (partly mental) effect due to this cause.

During totality the shadow covered most of the sky, but near the horizon to north and south there was a red glow, due to distant regions of the atmosphere beyond the shadow. (This effect was also seen in Norway in 1896.) The shadow was 120 miles wide, and the observer 9 miles north of the centre.

The corona was seen with direct vision to a distance of ¾ diameter from the limb, being very bright: with averted vision two faint extensions were seen, one to N.W., the other in the upper part, each 5 minutes wide and reaching to 1½ diameters from the limb; they gave the corona the appearance of a wind-vane, a simile used on former occasions. Mr. Russell's description of the corona mentions three immense "spearheads" of white light, one to the zenith, the other two on the lower side, the left-hand one being the larger; these formed "as it were a great forked beard." A ruby spot, doubtless a prominence, was seen on the low left hand.

A few stars were seen during totality, but they were not specified. An account in B.A.A. Journ. (Jan.) by Dr. A. F. Turner states that six were seen, of which Venus, Mercury, Jupiter, and Spica were identified; two that were seen far to the south may have been α and β Centauri.

PROBLEMS OF THE NEBULÆ.—The Rev. H. Macpherson contributes an article on the nebulæ to *Discovery* (March). The numerous and rapid changes of view that have taken place with regard to them illustrate the difficulty of knowing where to place them in schemes of stellar cosmogony. The "island universe" theory of the spirals was received back into general favour ten years ago, but Mr. van Maanen's detection of perceptible rotatory movements in several of them, in combination with the spectroscopic determination of radial velocities, enables hypothetical parallaxes to be estimated. These correspond to distances of a few thousand light years, so that they appear to be within the limits of our own universe. Dr. Jeans regards the luminous knots on the rims of these spirals as giant stars in process of formation at the rate of one every few centuries.

There is another difficulty not felt at the time when stellar types O, B, A were supposed to be the earliest in the spectral sequence, which the "Giant and Dwarf" theory renders puzzling: this is the frequent association of these types with planetary nebulæ in the case of O, and with bright diffused nebulæ in the cases of B, A (Orion and the Pleiades). It would seem that these nebulæ can scarcely be regarded as the parents of the stars that they surround, since, if such were the case, they would be much more in evidence round giant stars of type M. The conclusion appears to be that the natural condition of nebulosity is dark, but that it may become bright either by simple reflection, as appears to be the case with the nebulæ in the Pleiades, or by selective excitation, which causes some of its gases to glow. Prof. Russell compares this to the excitation that occurs in a comet when near perihelion.

Research Items.

ARCHÆOLOGICAL EXPLORATION AT ZIMBABWE.—A noteworthy contribution to the discussion of the origin and date of the Zimbabwe ruins appears in the recently issued vol. xx. of the Proceedings of the Rhodesian Scientific Association in the form of a communication from Mr. H. R. Douslin, lately Director of Public Works, on "Recent Explorations at Zimbabwe." Mr. Douslin has excavated the ruins on two occasions. In 1909 the trench made by Dr. Randall-MacIver in 1905 was carried down to solid rock by a pit under the wall of the Temple. The base of the foundations was reached at about 2 ft. and the rock at about 10 ft. below surface level. Only broken pottery, of a type common to all the ruins and similar to that made by natives to-day, was found. In 1915 excavations were carried out inside the wall of the Acropolis, which it is assumed was built before the Temple, and a large part of the red-earth filling was removed. The original entrance was discovered—a passage many feet below what is considered to be the original foundation of the wall on the western side. It ended against a dead wall of the internal red-earth filling. This filling, on which many of the internal walls are built, would therefore appear to be of more recent origin than the main outer wall. Solid rock was reached at about ten feet below present surface level, where the old dwellings were found. Their workmanship is superior to that of present-day natives and of a character unknown to them. The finds included two finely ornamented copper bands, an iron shackle, assegais, fragments of a soapstone bowl, and the usual Kaffir beads and pottery. No gold was found, and the author points out that the gold ornaments, etc., for which the greatest antiquity has been claimed, were found on or near the surface ten feet above the original occupation level.

SOCIAL SIGNIFICANCE OF U.S. ARMY INTELLIGENCE TESTS.—Prof. P. E. Davidson discusses in the *Scientific Monthly* (February 1923) some of the generalisations which have been drawn from the now well-known American Army intelligence tests. These tests, originally applied in order to differentiate men for army posts, disclosed the unwelcome fact that large numbers of the population ranked very low in innate intelligence. Some writers have concluded from this that the traditional democratic ideal must be renounced, as only a gifted few are capable of ruling. The writer of the article believes, however, that three assumptions have to be made if such conclusions are sound: (i.) that the army draft was truly representative of the American population in general; (ii.) that the tests were really tests of native ability and not of educational advantages; (iii.) that the native intellect in question is so general as to condition social success of any significant kind. He gives reasons for disputing each of these assumptions, and shows that large numbers of the more intelligent members of the community were unrepresented, that the tests made heavy demands on language knowledge, and that many factors other than native ability help to determine a man's social position. While agreeing that the gifted minority should have every possible advantage, he disputes the belief that these alone should be trained, while large numbers are to be denied training because of an arbitrarily imputed stupidity. The article gives a salutary and timely check to the ardent enthusiasts who would impute to tests more than they can legitimately bear. It is frequently the social applications of scientific research that are unscientific.

EFFICIENCY IN FINE LINEN WEAVING.—A report on fine linen weaving has been prepared by Mr. H. C. Weston on behalf of the Industrial Fatigue Research Board (Report No. 20, "A Study of Efficiency in Fine Linen Weaving," Textile Series No. 5, H.M.S.O., 1922, 1s. 6d. net). The investigation was undertaken for the purpose of enabling a comparison to be made between the conditions of work and efficiency in linen-weaving sheds and in cotton-weaving sheds, the latter having previously been investigated. The output from each of forty looms was recorded, hourly readings of the wet- and dry-bulb temperatures were taken, and the amount of time noted during which artificial light was used. A detailed description of the nature of the weaving process is given and the general conditions of the sheds. Tables showing the hourly, diurnal, daily and weekly variations of efficiency and temperature are appended. The writer concludes that there is evidence to show that the economic limit of temperature for fine linen weaving is reached when the wet-bulb temperature exceeds 73° F. Up to this limit increase of temperature results in increase of productive efficiency, but beyond it efficiency falls owing to the discomfort and fatigue of the workers. He also shows that the use of artificial light reduces efficiency approximately by 11 per cent. of its normal daylight value. A similar result was reported in a previous investigation made by the Industrial Fatigue Research Board into silk-weaving. These results are not unworthy of consideration in discussions of daylight saving.

THE DISTRIBUTION OF MEGALITHIC MONUMENTS IN ENGLAND AND WALES.—In the Proceedings of the Manchester Literary and Philosophical Society (vol. lxv. No. 13) Mr. W. J. Perry supplies some further arguments in support of his theory that megalithic monuments were the work of a race of miners engaged in the search for precious metals and other valuables. This he holds to be established in the cases of Cornwall, Devonshire, Wales, Derbyshire, Northumberland, and Cumberland. The difficulty remains regarding those in Dorset, Wilts, and Oxford, including Stonehenge and Avebury. The explanation is that this latter series is situated on the Upper Chalk flint-bearing formation. "Flint implements," he remarks, "are found in all parts of the country, even in places far away from the source of the material. Sir John Evans mentions particularly Devon and Cornwall as regions where there is an abundance of flint implements and flakes, and these counties have no flint-bearing formations, though in some places there are some on the surfaces. These would not be nearly so good for the purpose as those from the chalk regions of Wilts and Dorset. We have thus the remarkable fact that flint implements are found all over the country, and that the builders of megaliths, including long barrows, have chosen out those very portions of the chalk country which produce flints."

DISTRIBUTION OF ORGANISMS IN CULTURE MEDIA.—As a rule the accuracy of biometrical determinations must be ascertained empirically from a statistical study of the observations; in certain cases, as has been shown in the theory of hæmocytometer counts, the law of variation may be calculated, and the accuracy known with precision, provided the technique of the counting process is effectively perfect. A study of the extensive bacterial count data accumulated at Rothamsted by Cutler and Thornton, using Thornton's agar medium, indicated that the

same law of variation, the Poisson series, was obeyed by the number of colonies counted on parallel plates. Statistical tests were devised which proved that, save for a small proportion of definite exceptions, the necessary perfection of technique was effectively realised (R. A. Fisher, H. G. Thornton, W. A. Mackenzie, *Annals of Applied Biology*, vol. ix. p. 325, 1923). In studying the exceptional cases it appeared that these fall into two classes, (1) an abnormally high variation which, when investigated experimentally, has been traced to certain bottom-spreading organisms isolated from soil from Leeds and from Rothamsted, and (2) an abnormally low variation ascribable to defective procedure in the preparation of the medium. Application of the same tests to other extensive series of bacterial counts showed that a similar approach to theoretical accuracy, though rare, had been obtained by Breed and Stocking in counts of *B. coli* in milk. It should be emphasised that all cases of departure from the theoretical law of distribution, which have been investigated, are associated with large systematic errors in the means; for this reason simple tests are presented by which such deviations from the theoretical accuracy of the method can be detected.

PRIMULAS OF CENTRAL ASIA.—Mr. F. Kingdon Ward, who was referred to in NATURE of February 17, p. 231, as returning to England after extensive travels in Central Asia, has been contributing some account of his previous (seventh) expedition in Asia in the *Gardeners' Chronicle* since May 1922. These articles not only describe very vividly the first discoveries of many new plants, to be of interest afterwards to the British growers of novelties, but also frequently raise interesting general questions from the point of view of a keen observer of plants; as, for example, the discussion in the issue of February 10 (p. 80), as to the association of meal—a granular waxy deposit developed on the cuticle—and fragrance in the Primulas, and the observation that the Primulas found growing on boggy habitats are generally without meal.

THE CUTICLE OF COTTON.—A paper by R. G. Fargher and M. E. Probert, in the Journal of the Textile Institute, vol. 14, pp. T49-T65, February 1923, seems to represent a notable advance in our knowledge of the chemical composition of the plant cuticle. Material extracted from American cotton by benzol, heating with superheated steam, was available from some very large scale experiments. This method opens up the possibility of hydrolysis during extraction, but the large bulk of material made available by the scale of operations has provided very precise information as to certain constituents of the cotton wax, although doubt may remain as to the exact form in which they are present in the cuticle. A new alcohol, gossypyl alcohol, $C_{30}H_{62}O$, is identified and described, montanyl alcohol, $C_{29}H_{58}O$, present in smaller amount, is also described for the first time; small amounts of ceryl and carnaübyl alcohol were also found, and a mixture of phytosterols; little if any glycerol was present. Palmitic, stearic, and oleic acids were found in the free state, the sodium salts of montanic, cerotic, palmitic, and stearic acid were identified, as well as the salt of an acid, $C_{31}H_{60}O_2$, oleic acid and a lower isomeride of oleic acid were present as esters, but the proportion of unsaturated acids, either free or combined, was small. While this work, on one hand, will throw much light on the problem of scouring cotton, on the other, it gives much needed information as to the chemical constituents of the plant cuticle.

THE ISOETACEÆ.—Norma E. Pfeiffer has published a most valuable systematic study of this family in the Annals of the Missouri Botanical Garden (vol. 9, No. 2, April 1922). After a brief account of the morphology and ecology of the genus, which is incomplete as a bibliographical account of European work upon Isoetes, the species are grouped into sections, and keys are provided for the identification of species within the sections. Breaking away from former systematic studies, where habitat characters have largely been used for the establishment of main subdivisions, the present sections are based upon the megaspore surface, whether tuberculate, spiny, crested, or reticulate. Within the sections great use is made of the lobing of the corms and the amount of development of the velum; megaspore characters are again frequently used, and eight plates are provided with photographic illustration of megaspores of different species. The family is a remarkable one to the student of plant distribution. Of the 64 species described, most are very restricted in range, the only exceptions being *Isoetes Braunii*, Dur., in North America, and *I. lacustris* and *I. echinospora* in Europe. Some of the Mediterranean forms appear to the author to show close affinities, as though originating from a common stock; but, on the whole, present knowledge of the species and their distribution is too puzzling, and probably too incomplete, to encourage premature speculation as to centres of distribution and evolutionary tendencies. It is interesting to find one submerged species—*I. echinospora*—always without stomata while *I. Braunii* always possesses some.

PHYSIOGRAPHY OF PORTO RICO.—A detailed study of the physical geography of the West Indian island of Porto Rico by Mr. A. K. Lobeck is published by the New York Academy of Sciences (vol. i. pt. 4). It is the last section of a complete survey of the island undertaken by the Academy. The present part, which includes a large-scale map, is the outcome of field work in 1916–17. The physiographical history of Porto Rico appears to have begun with a complex mass of igneous rocks which were eventually reduced to a peneplain, except for two well-defined monadnock groups, now known as the Luquillo mountains and the Cordillera Central. No direct evidence on the horst nature of this ancient land mass was available. Uplift of the peneplain led to a new cycle of erosion, but only along the northern side of the island was a second peneplain produced. On the south the island was worn down less effectively, probably because of inadequate rainfall. Partial submergence then allowed the formation of coastal plains on both north and south sides which, after uplift, were considerably dissected. Mr. Lobeck traces these events and discusses also recent changes now in progress, illustrating his lucid paper by photographs and block diagrams. Some notes are added on the islands of Desecheo, Mona, Vieques, Culebra, and Muertos.

PLIOCENE VERTEBRATES FROM THE TERTIARIES OF ARIZONA.—On the initiative of the United States Geological Survey and with the co-operation of the United States National Museum, Mr. J. W. Gidley went early in 1921 to collect fossil vertebrates in the San Pedro Valley, Arizona, with the view of establishing the age of the deposits there, which until then had been termed Pleistocene. A preliminary report has now been issued as Professional Paper 131-E of the United States Geological Survey. Unfortunately the material collected represents for the most part new species which cannot therefore be correlated with known faunas of other localities

where the age of the beds has been established. With two or three species of true horse (Equus) are associated the remains of Hipparion, Pliohippus, some Proboscidia, Camelidæ, Cervidæ (including Merycodus), Carnivora, numerous Rodentia, and Glyptotherium, as well as reptilian and bird remains. The author, therefore, refers these beds to the Pliocene, and points out that the presence of a true llama, a glyptodont, and a rodent belonging to a genus now living only in South America, bears out the theory of the derivation of the South American fauna by migration from North America, and that such migration may have taken place about this epoch. Detailed descriptions, with figures, of the Rodentia and Leporidæ, all of which represent new species and total some twenty in number, form the major portion of the paper. The reptiles and birds are to be dealt with later by other writers.

THE HIMALAYAN MOUNTAIN SYSTEM IN SOUTH-EAST ASIA.—One of the objects of Prof. J. W. Gregory's recent journey to Yunnan was to study the geographical relationships of the Alps of Chinese Tibet. A sketch of his conclusions appears in the *Geographical Journal* for March. He contends that the structure of western Yunnan is best explained on the view that the line of Himalayan folding is not wholly bent in Assam into the Burmese arc which follows the Arakan mountains, the Andamans, and the Nicobars into Sumatra, Flores, and Timor. Two routes have been suggested as the eastern prolongation of the Himalayas, the Great Khingan mountains, and the Tsinling mountains. The former view is untenable owing to the essential difference in structure; the latter is a doubtful thesis since there are indications that the Taliang Shan of southern Szechwan, which would appear to be a link in this chain, are east and west folds of Hercynian age. The evidence is more in favour of the Himalayan line being continued in the Nan Shan mountains, which separate the Yangtze Kiang from the Si River, although information as to their geological structure is still meagre. According to Prof. Gregory's interpretation, the Burmese-Malay arcs of folding form a loop on this eastern prolongation of the Himalayan axis comparable with the Persian loop in western Asia and the Apennine loop in Europe. The eastern end of the Malay arc is generally represented as a reversed bend round the Banda Sea. Prof. Gregory agrees with Suess that this is not so, and holds that the Malay arc continues into the mountains of south-eastern New Guinea. On the north of the Banda Sea these folds are also obvious and are continued in the northern mountain axis of New Guinea. But the eastern end of this line of folding is now cut across by the Pacific, into which it must at one time have extended. The paper also contains important evidence on the river system of Chinese Tibet.

PERIODICITY OF EARTHQUAKES.—Messrs. D. Mukiyama and M. Mukai, in a paper too brief to be quite clear (*Japanese Journ. of Astr. and Geoph.* vol. 1, 1922, pp. 49-54), indicate a general similarity in the deviation of the atmospheric pressure-gradient at the time of an earthquake from the mean pressure-gradient in each of four selected districts in Japan. The question of the influence of rainfall on earthquake-frequency is considered, as regards the Philippines, by the Rev. M. Saderra Masó (Bull. of the Weather Bureau for February 1921). He shows that in the western districts of both Luzon and Mindanao earthquakes are most frequent during the rainy season, but in the eastern districts of both islands during the dry season. Thus, though rainfall may have some influence, it cannot be the main determining factor in the frequency of earthquakes. The late Mr. Marshall Hall, in his study of the earthquakes of Jamaica from 1688 to 1919, suggested the existence of nearly forty earthquake-periods varying in length from about 10 to about 30 days in the different epicentres, especially one of about 21 days in the epicentre of the earthquake of 1907. These periods have been examined by Prof. Turner (Mon. Not. R.A.S., Geoph. Sup., vol. 1, 1923, pp. 31-50), who arrives at the interesting results that they are multiples of 21·00 minutes, and that the intervals between the means of these periods are also multiples of the same unit, or 0·0145843 day.

STRUCTURE OF BENZENE.—In the February number of the Journal of the American Chemical Society, Dr. M. L. Huggins discusses the structure of graphite, benzene, and other organic compounds from the point of view of X-ray measurements by Hull and by Debye and Scherrer. He concludes that graphite consists of layers of close-packed benzene complexes of the type proposed, from the point of view of organic chemistry, by Körner in 1874. This is built up of six tetrahedra, three on each side of a plane, with edges adjacent, and with the vertices alternately above and below the plane. On the assumption that similar close-packed layers are present in benzene and many of its derivatives, the dimensions of the benzene hexagon are computed from crystallographic data. The half length of this is 2·47 Å., the half-width 2·14 Å., and its area 15·84 Å.^{2}. The corresponding figures from Debye and Scherrer are 2·52 Å., 2·18 Å., and 16·47 Å.^{2} The probable error in each case is about 1 per cent.

SPACE GROUPS AND CRYSTAL STRUCTURE.—With the development of such methods of studying the arrangement of the atoms in crystals as are furnished by the use of X-rays, the geometrical theory of space groups has become of the utmost importance. Until recently the work published upon this theory has been primarily directed towards the preparation of a statement of all the different kinds of symmetry which are crystallographically possible. Such a statement, when complete, must give all the possible ways of arranging points in space which, by their arrangement, express crystallographic symmetry. In his "Krystallsysteme und Krystallstructur" (Leipzig, 1891) Schoenflies gave an analytical expression for the results of this theory in its most general form, but, before it is applicable to the study of the structures of crystals, modifications of this original representation are necessary. First, there must be selected such a portion of the grouping that, in its calculated effects upon X-rays, it can be taken as typical of the entire arrangement. Secondly, the X-ray experiments which have already been carried out show that the number of particles (atoms) contained in the unit cell is commonly smaller than the number of most generally placed equivalent points of the space group having the symmetry of the crystal. The special arrangements of the equivalent points (upon axes, planes, and other elements of symmetry), whereby the number of most generally placed equivalent positions is reduced, are thus of great importance, and it becomes essential to be able to state all of them in any particular case. In his "Geometrische Krystallographie des Discontinuums" (Leipzig, 1919), Niggli has given the simpler of these special cases. The complete set of them, enumerated by R. W. G. Wyckoff, is now presented in "The Analytical Expression of the Results of the Theory of Space-Groups," in Publication 318 of the Carnegie Institution of Washington, 1922; price 3.25 dollars.

The Dyestuffs Industry in Relation to Research and Higher Education.[1]

By Dr. HERBERT LEVINSTEIN.

WITHIN one generation we have seen the small mechanics' institute in a provincial city develop into an institution of university standing, constituting a technological faculty giving degrees, with some of its professors sitting on the university senate. In one way or another London, Birmingham, Bristol, all the large cities, show the same change. It means that within this period an enormous change has taken place in the character and requirements of our industries, and consequently in the demand for highly trained young men. The industrial world has changed. The present characteristic of industry is the tendency towards large units, using as one of their weapons an intelligence department (a research department), equipped with every resource of science. This is in itself nearly as far removed from the Victorian system of industry as that was from its predecessor, and it is causing nearly as great a social change as the industrial revolution that followed on the introduction of machinery.

The scientific educational establishments in this country are fundamental to the whole structure. By the vitality and originality, by the number and the quality of our teachers, the world can judge of the capacity of Great Britain in the long-neglected scientific industries, of which dyestuffs and fine chemicals are pre-eminent.

The dyestuffs industry is what is loosely termed a key industry. Mr. Runciman, speaking in the House of Commons on November 27, 1914, said: "The combined capital of such operations of textile and other industries which require aniline dyes comes to no less than 200,000,000*l*., and about 1,000,000 of our employees are either directly or indirectly interested in the adequate supplies of dyestuffs for their main industries." There were few people who questioned at that time the urgency and importance of producing within our own shores the commodities required to support so many staple industries. We were at war with Germany, on whom we had been dependent in peace time for 80 per cent. of our requirements, and at that moment it was necessary, both from an economic and military point of view, to replace at once those vanished supplies from home sources.

What happened after the War? In 1913 the dyestuffs industry in England supplied about 10 per cent. of the British consumption, which amounted in round figures to rather more than 20,000 tons. The factories were comparatively small, and the number of chemists proportionately few. By Armistice Day the two principal companies, already loosely united, employed some 7000 persons, nearly 300 of whom were academically trained chemists—an unheard-of number in this country. During the two years following the Armistice more than 25,000 tons of dyestuffs manufactured by this British company alone went into consumption in Great Britain.

The extraordinary prosperity in the textile trades at that period had its aftermath in the slump. In 1919, however, the employment provided by these trades, and the money brought into this country as payment for exports, were factors without which this country would not have readily recovered from the paralysis of war. The total value of the exports of printed and cotton dyed piece goods alone during 1919–20 amounted to 270 million pounds sterling. In October 1920 the British Dyestuffs Corporation alone employed some 8000 people, with a yearly wage roll of 1,600,000*l*. This company used 4000 tons of coal per week, 1000 tons of pyrites, and corresponding quantities of heavy chemicals and raw materials. These figures may be considered large in this country, where we are not so familiar with very large plants, but they are small compared with the aggregate of the German I.G.

Suddenly in October 1920 the slump fell upon the country. The position was made much worse by four factors. German production revived, considerable quantities of German dyes were imported as reparations, the Sankey judgment temporarily removed all protection from the home producer, and the rapid external depreciation of the mark temporarily made it difficult to compete with Germany in neutral markets. Stocks fell in value, large sums of money were lost, and the production of British companies fell almost to pre-war figures.

The dyestuff and fine chemical industries in this country, are by no means assured of a prosperous, development. If the factories are allowed to decay, the staffs to be gradually diminished, the capital invested rendered unremunerative, our position will become less strong. At the moment, should the occasion arise, the factories and organisations created during the war years are a source of strength.

The developments of higher scientific education in this country, on which our scientific industry is based, tend to strengthen the national life in a way which may not be immediately obvious but yet quietly and unobtrusively may be of fundamental importance to the State. There is another reason of great importance in favour of a flourishing and progressive dye industry. The dye industry is a key industry to invention. Its importance as a factor in producing new inventions is well summarised by Mr. J. A. Choate, the author of an official American publication issued by the Alien Property Custodian of the United States Chemical Section:

"The Technical skill and equipment provided by a successful Dye Industry, furnishes the means, and almost the sole means, to which every nation must look for advances in the application of chemical science to practical undertakings. No other industry offers a livelihood to any such large numbers of highly trained scientific chemists nor any such incentive to continuous and extended research."

Any firm wishing to become a serious factor in the world's markets for fine chemicals and dyes must employ a number of research chemists. Existing products tend towards obsolescence, competition from other makers tends to lower their price, and new demands constantly arise and are satisfied or created by new products for which high prices can be obtained owing to their novelty and, at first, the absence of competition. In the long run that nation will predominate in this industry which brings out the best and the largest number of new products.

These research organisations are expensive. Why then did the Germans start in this race for new products? They found this kind of research to be extremely profitable to their shareholders. Consequently, it was developed, and they were able to bring out annually quite a number of new products which, pushed by enterprising salesmen in all markets, home and foreign, gradually became established branches of manufacture in Germany.

Research for new products costing no more than the old, but for which the public will pay a higher price, is intimately wrapped up with the question of patents. Without the prospect of a monopoly for a term of years, and the lure of high profits, this kind of

[1] From a paper read before the Association of Technical Institutions on March 3.

work would not be undertaken on a comprehensive scale. Unfortunately, the monopolies granted in our country in the past for this kind of work were granted to German industries, and not to our own, and large profits were made out of British patents by the German dyestuff works. A similar research system, if sufficiently supported on the commercial and technological side and directed with sufficient knowledge of the requirements of the industry, and with some imagination, can be made to pay in England just as in Germany, where this combination existed. It is important to remember that firms employing this modern commercial weapon were large, for the amount of money that can be spent on research is a function of the turnover.

It is further true that to build laboratories, to engage for them a number of chemists, are not alone sufficient for our success.

If the stream of chemical invention can be induced to flow in this country in the future not less sluggishly than in Germany, we shall gradually build up new industries as the Germans built up theirs.

In this country we rely too much on our staple industries and look too little for new inventions to find food and employment for our people. In the Report of the Department of Scientific and Industrial Research, 1921–22:

"... It is well recognised that for four-fifths of their food and for a great part of the necessary raw and semi-manufactured materials for industry the people of these islands are dependent on supplies from overseas. These supplies can only be obtained if this country is able to carry on its exporting industries in future with greater efficiency than the rest of the world."

The Department spent in this year more than half a million pounds with this purpose in view, and provision is made for expenditure on a similar scale for the current year. Under its auspices no less than 24 Industrial Research Associations have been formed, of which 22 are licensed by the Department, and received more than 86,000*l.* in grants during the year in question. Broadly speaking, the work of the Department and of the Research Associations with which it collaborates is to ensure the best utilisation of our natural resources and of the raw materials which we buy from abroad for our staple industries, with the view of increasing the efficiency of those industries and enlarging the demand for their products in customer countries.

This work does not replace that of private firms, but is complementary to and ought to stimulate it. There is a radical difference between industrial research carried out by a company and that by a Research Association, or by a Department of State. Patents taken out by chemists who receive part of their emoluments from the Department, belong apparently to the Government. Patents which may be taken out by a Research Association would presumably be available for all subscribers and could not easily become a profitable monopoly for any one member. For this reason it appears likely that in the future, as in the past, the dyestuffs industries and the allied fine chemical industries will be the main source from which chemical discoveries will be transferred from the laboratory to the factory.

Running through all this is one common factor which must be realised if the expectations of the State are to be satisfied. The industry must be big. There must be large factories containing plant capable of producing great quantities of organic chemicals, staffed by an adequate number of experienced and well-trained chemists. Moreover, the factories must be growing. It is an industry which cannot succeed if it be static. It must be ever increasing its plant and the number of its chemists and ever spreading its tentacles wider and deeper into the markets of the world.

It follows that if the industry is successful there will be a continual flow of students from the universities and technical schools to the industry. Two distinct classes of chemical students are required: (*a*) for factory and research, and (*b*) for the dyehouse and technical sales. It is customary in aniline dyestuff factories to recruit the chemists for plant supervision from their own research department. The young chemist engaged on leaving the university is first placed in the research department for at least a year before a permanent engagement is made. The training required of a dyestuff works chemist is usually identical, whether he intends to devote himself afterwards purely to research, or, as in the majority of cases, to become actually employed in the factory. It is of the first importance that chemists should have a good general secondary education. After taking his degree the student should cary out, under direction, original work for one or, preferably, two years. What branch of organic chemistry he studies is comparatively immaterial. A special knowledge of dyestuffs chemistry is not very important.

Undoubtedly a knowledge of chemical engineering is useful, but subjects added, however useful, will be at the expense of chemistry. The recent formation of the Institution of Chemical Engineers is welcome. Good chemical engineers are invaluable in any chemical industry, but, above all, good organic chemists are wanted in the dyestuff industry.

There is also a considerable demand for another type of chemist. All aniline dye works have a dyehouse which fulfils a treble function—the control of the production, the valuation of new specimens sent in from the research department, and the supply to the sales organisation of technical information and assistance in the application of dyestuffs. The technical salesman is a person of great importance in the industry. He should preferably take a pure or technological science degree, followed by a course in dyeing, printing, paper-making, etc., at a technical college. There is a constant demand for such men in a flourishing dyestuffs industry, the more so as the experience obtained in the experimental dyehouse is so varied, that such men are afterwards sought for as managers or as assistant managers in print-works, dyehouses, paper-works, and the like.

The foundation stones of our scientific industries were laid by those responsible for the creation of our great technical institutions and University Colleges. If that is so, we should expect to see during the years which have elapsed since 1914 a corresponding development in the chemical schools of this country. The progress in the study, teaching, and research in pure chemistry has been at least as striking as the progress of those sections of chemical industry such as fine chemicals and dyestuffs in which we were not particularly strong before the War. Twenty or thirty years ago the German organic schools were as pre-eminent in research and in teaching as the German dyestuff and fine chemical industry. To-day one may fairly say that there are several organic chemical schools in this country equal to that of any organic chemical school in Germany. Brilliant original work is being done here. Students are attracted to schools where good research is being done, and so round each head is formed a coterie of young men deriving inspiration from their chief, to strengthen the ranks of industry. Probably there has never been such a concentration of chemical talent as that which gathered round A. von Baeyer in Munich thirty or forty years ago, but something of the kind is happening in Great Britain to-day, and not in one centre alone.

Thirty years ago, institutions comparable, for

example, with the Federal Polytechnic at Zurich or the Technical High School of Charlottenburg did not exist in Great Britain. The scale on whch they were designed, their large staffs of distinguished teachers, the number of full-time students, students who had remarkably good secondary school training and had passed a rigorous entrance examination, astonished all English visitors. The English organic chemist with industrial experience was equally astonished at, for example, the Leverkusen or the Badische factories. These factories differed from the corresponding English factories in scale, in the size of the buildings, their staffs, their financial results, just as the British schools differed from the corresponding German institutions.

The number of students taking a degree in pure science at 17 English and Welsh Universities in 1913–1914 was 1867. In 1921–22 the number was 4575, *i.e.* about two and a half times the 1913–14 number. At the University of Cambridge the figures were as follows:

	1913–14.	1921–22.
Number of chemical students working	498	804
Research workers	10 (about)	29
Staff, including professors	25	43

The growth of the dyestuffs industry within this period is well known, and there has been a similar growth in the fine chemical industry. In 1913 some 100 fine chemicals were made in England, whereas 4000 are now being made; for every ton of fine chemicals made here in 1913 exactly 2½ tons are made to-day. This ratio is identical with that of the increase in science students taking a degree course.

Is it possible that this parallel growth in our teaching institutions and newer industries is accidental? The figures are symptomatic, but they indicate that the strength of our higher teaching bodies is a measure of our strength in the industries depending on invention.

It may be said that there has been in Germany, too, and no doubt in other countries, a great increase in the number of students at their High Schools. In part this is one of the social changes brought about by the new industrial revolution.

The increase in the number of chemical students is partly due to the publicity given in 1914 to the renascent dyestuffs industry, and to the support given by public opinion and by the Press for the first time in our history to those engaged in these industries. These industries open out to a young man who has a love of research the opportunity of earning a livelihood in a most interesting way, with the added possibility, if his inventions prove commercially successful, of earning considerable profits. Before the War it was difficult to live by research.

It is probable that the grants made by the Department of Scientific and Industrial Research have tended to increase the number of chemists undertaking training, "for the underlying object of the Scheme of Grants is the output of an increased number of trained scientific investigators." At the same time, the Department has done much to increase the possibility of finding employment for chemists. The Department, including its headquarters staff, boards and committees, Fuel Research Station and the Research Associations, already employs 78 chemists, none of whom were employed in 1913, at salaries ranging from about 250*l.* to 2000*l.*, the majority between 350*l.* and 700*l.* In other Government Departments, too, there has been a great increase in the number of chemists employed. In 1913–14 the staff of the Government Chemist consisted of 48, with a salary range of 120*l.* rising to 1500*l.* The majority of the posts ranged from 120*l.* to 500*l.* In 1921–22 there were 75 posts, ranging in salary from 300*l.* to 700*l.* At the War Office in 1913–14 there were 22 posts and 2 teaching posts at the Ordnance College. The salary range was about 150*l.* to 550*l.* In 1921–22 there were 93 posts, with salaries ranging from 300*l.* up to 1200*l.*, but with the majority falling within a range of 300*l.* to 700*l.* At the Admiralty in 1913–14 there was one inspector of cordite, in addition to the teaching staff at the Royal Naval College at Greenwich and the schools at Dartmouth and Osborne. In 1921–22, in addition to these teaching staffs, there were 20 posts with salaries of from about 150*l.* to 600*l.* The total number of chemists who can to-day find employment in the service of the above Government Department is thus 193 more than in 1913.

In the 1921 report of the Department it is stated that of the 132 students receiving grants 24 found employment under the State or under State-aided research institutions, 22 went into the teaching profession, and none went into industry, no doubt owing to the slump in trade.

If our fine chemical industries begin to increase their staffs regularly, as in prosperous years they will, the situation will be improved, but it is to the general trade of the country and not to the specifically chemical industries that we must look to give employment to all those who have taken a chemical degree.

Large Telescopes and their Work.

SIR FRANK DYSON'S presidential address to the Optical Society on February 8 on the subject of "Large Telescopes" dealt with the progressive advance of astronomy so far as it was brought about by the increased optical powers of telescopes. The Copernican system was established before the discovery of the telescope, but Galileo's telescope removed many difficulties and commanded its acceptance. The great telescopes of Herschel revealed the vast extent and variety of the stellar system. At the beginning of the nineteenth century, excellent achromatic telescopes of 6 inches were made by Fraunhofer and Merz, and in 1824 an object glass of 9·6 inches was made for Struve at Dorpat with which he carried out his great work on double stars.

When the Russian National Observatory at Polkovo was founded a 15-inch glass was obtained from the Munich firm, and this was the largest refractor in the middle of the nineteenth century. The large telescopes of this time were the reflectors of Lord Rosse and Lassell, and with them the heat from the moon was measured and new satellites of Uranus and Neptune discovered. A new development in reflecting telescopes came with the process of silvering on glass, and gradually these superseded speculum. In England in the early 'eighties photography of nebulæ began with Common's photograph of the Orion nebula, and was pursued by Isaac Roberts. The manufacture and mounting of reflectors was brought to a high degree of perfection by Ritchey at the Yerkes Observatory, but it was with the Crossley reflector, made by Calver and presented to the Lick Observatory by Sir Edward Crossley, and remounted by Keeler, that most systematic work was done.

Meanwhile, larger refractors were being made. In 1868 one of 26 inches aperture was made by Cooke for H. S. Newall of Newcastle. This was soon followed by large telescopes in America by Alvan Clark, by Grubb in England, and the brothers Henry

in France. In 1892 a 36-inch glass was made for the Lick Observatory by Alvan Clark, and a 40-inch for the Yerkes Observatory in 1897. These large telescopes led to the discovery of new satellites, the accurate determination of the sizes of planets and satellites, but their main work—used visually—was the discovery and measurement of large numbers of double stars, leading to a very satisfactory knowledge of the masses of stars. Used with the spectroscope, they gave the velocities of stars to and from the earth, and enabled the velocity of the sun among the stars to be determined as 19 kilometres per second. This result, in combination with measurements of angular motions of stars, served to give the mean distances of stars. Large photographic refractors have made possible the measurement of the actual distances of thousands of stars, leading to a much more complete view of the stellar system.

The discoveries made by the large 60-inch and 100-inch reflectors of Mt. Wilson and the 72-inch of British Columbia were also detailed, culminating with the measurement of the size of the disc of Betelgeuse and of several other stars by the interferometer as applied by Michelson.

Irish Sea Plankton.[1]

SIR WILLIAM HERDMAN, in an interesting paper recently issued, gives a summary of plankton researches in a single area extending over a period of fifteen years, and compares the results in each year in such a way that certain general facts are at once apparent.

The object of the investigations was twofold: "(1) To study the distribution of the plankton as a whole, and of its various constituents during the year; and (2) to arrive at some estimate of the representative value of the samples collected in the plankton nets."

The results show very clearly that the distribution of life in the sea is not uniform, but that the organisms appear in patches. Although this applies to a certain extent to all the plankton, it is especially the case with the copepods, which are frequently present in large swarms in one place, while possibly only a short distance away few or none occur. This naturally affects the distribution of other organisms feeding on the copepods, especially fishes, and is of fundamental importance. The diatoms were found to be more evenly distributed both vertically and horizontally during their maximum in the spring than at any other time. Comparing the records for the fifteen years (1907–21), there is always this spring maximum of phytoplankton (chiefly diatoms), which may range from March to June and reach to hundreds of millions in one haul, a dinoflagellate maximum, in much smaller numbers, coming on about a month later; and later still, a copepod maximum ranges from June to October. In late summer or autumn each group may have a second smaller maximum in the same order.

That the bulk of the plankton consists of a small number of genera, chiefly diatoms and copepods (and only a few species of copepods), is well established, and these few form the chief food of most of the marine animals. So far as fishes are concerned, copepods are by far the most important food of the young stages, and also of the plankton-eating adults; but as most copepods are predominantly diatom feeders the presence of diatoms is quite as important to the fish as to the copepod. With regard to the phytoplankton, however, Sir William Herdman apparently regards it as the direct food of many larval fishes, at any rate of the plaice in its infancy, which he has seen with its stomach full of diatoms.

The diatom maximum occurs usually just before the time when most of the fish larvæ begin to be abundant, and the copepods follow. These plankton investigations are thus of great importance relative to the food of fishes.

Dr. Johan Hjort suggests that large mortality among the fish larvæ may occur because of the lack of suitable food at the time when they begin to feed. In the present plankton investigations, together with data gathered from experiments in the plaice hatching at the Port Erin Biological Station, it is shown that diatoms are abundant usually a short time before the very young plaice are set free; but in four out of thirteen years the diatoms were late, and in these years it is possible that the young fishes may not have found enough to eat. "The evidence so far seems to show that larvæ set free as late as March 20 are fairly sure of finding suitable food: but if they are hatched as early as February they run some chance of being starved."

While discussing fully the phytoplankton in relation to fish larvæ very little is said of the zooplankton other than copepods, and one would infer from the conclusions that it is only the diatoms which are of importance as young fish food in the spring. It is, however, probable that in spite of the fact that more diatoms than anything else are present, yet the zooplankton is really of more direct value as food for the larval and post-larval fishes: for example, cirripede nauplii and mollusc larvæ besides copepods, the latter, although not at their height in the spring, yet occurring in large numbers.

Sunlight is shown to play a very important part in the growth of the plankton. In the daytime, however, the largest hauls are usually not at the surface but at about five or ten fathoms, the depth varying with the meteorological conditions. It is regarded as probable that the spring phytoplankton maximum is due chiefly to the great increase of sunlight aided by the winter increase of carbon dioxide and other food matters. The rapid disappearance of the diatoms after the spring maximum is accompanied by a greater alkalinity of the water, and it is suggested that it may be due to the injurious effect of their own metabolism. May not the explanation lie partly in the fact that the diatoms are eaten by an enormous number of pelagic animals coming on just after the diatom maximum?

As to the representative value of the samples collected in the plankton nets, it is shown that variation in the composition of similar hauls is great. These differences show clearly that the life in the sea is not spread evenly either horizontally or vertically, but everywhere occurs irregularly. Simultaneous hauls of similar nets were usually different in quality even if alike in quantity, and the same applied to successive vertical hauls in which the amount of organisms was much the same in each haul but different in kind.

In plankton investigations in which tow-nets are used, however carefully the experiments may be carried out, there is necessarily a great deal of inaccuracy, which is freely admitted and discussed. None of the numerical results can be absolutely exact, but when, by examining and recording these, certain phenomena are seen to repeat themselves year after year, we can at least feel sure that by making these careful quantitative experiments in connexion with numbers of hauls all carried out in an exactly similar way, we are approaching the solution of the general problems relative to the distribution of life in the sea.

M. V. L.

[1] "Spolia Runiana. V. Some Results of Plankton Investigations in the Irish Sea," by Sir William Herdman. Extracted from the Linnean Society's Journal—Botany, vol. xlvi., July 1922.

University and Educational Intelligence.

BRISTOL.—Dr. L. J. Russell, lecturer in philosophy at the University of Glasgow, has been appointed to the chair of philosophy which will be vacated by Prof. C. D. Broad at the end of the current session.

CAMBRIDGE.—The Duke of Devonshire has been elected High Steward of the University in succession to the late Earl of Plymouth. So far back as the fourteenth century a Cavendish held high office in the University, and the name of Henry Cavendish is perpetuated in the Cavendish chair of experimental physic.

Mr. G. S. Adair, scholar of King's College, Mr. P. M. S. Blackett, Bye-fellow of Magdalene College, and Mr. B. Ord, organ scholar of Corpus Christi College, have been elected fellows of King's College.

LEEDS.—The Council has agreed with the University of Basle to a scheme of mutual recognition of certain courses and examinations in the case of students proceeding from either of these Universities to the other.

LONDON.—Prof. A. V. Hill has been appointed as from August 1 next to the Jodrell chair of physiology tenable at University College. Prof. Hill was educated at Trinity College, Cambridge. He was Third Wrangler, and obtained a first class in physiology in the second part of the Natural Sciences Tripos. He was fellow of Trinity College from 1910 to 1916, and in the latter year was elected fellow of King's College. During the War he was director of the anti-aircraft experimental section of the Munitions Inventions Department and a member of the Inventions Committee. Since 1919 he has been professor of physiology in the Victoria University of Manchester. He is the author of a number of papers in the Proceedings of the Royal Society and the *Journal of Physiology*.

Mr. W. J. Perry has been appointed as from August 1 next to the University readership in cultural anthropology tenable at University College. He was educated at Selwyn College, Cambridge, and studied ethnology under the late Dr. Rivers. Since 1919 he has been reader in comparative religion in the Victoria University of Manchester, and has also delivered courses on ethnology in the department of psychology of that University. He is the author of "The Megalithic Culture of Indonesia," "The Children of the Sun," and "The Origin of Magic and Religion," and of numerous papers on ethnological and anthropological subjects.

Dr. B. Malinowski has been appointed as from August 1 next to the University readership in social anthropology tenable at the London School of Economics. From 1914 to 1918 he was engaged in anthropological field-work in Eastern New Guinea. He is the author of "The Family among the Australian Aborigines" and "Argonauts of the Western Pacific," and of a number of articles on anthropological and allied subjects.

The following doctorates have been conferred:—*D.Sc. in Agricultural Chemistry:* Mr. N. M. Comber, an external student, for a thesis entitled "The Flocculation of Soil Particles considered in relation to the Action of Lime and the Constitution of the Soil," and other papers. *D.Sc. in Physics:* Mr. E. T. Paris, an external student, for a thesis entitled "On Doubly-Resonated Hot-Wire Microphones," and other papers.

The Senate has resolved to hold a reception for the sixth triennial congress of the Société Internationale de Chirurgie, which will be held in London in July next.

MANCHESTER.—The chairman of the council, Sir Frank Forbes Adam, has received from the Viscount Morley of Blackburn a letter asking leave, on account of the growing weight of years, to withdraw from the office of Chancellor of the University, the resignation to take effect from April 30. The council passed a resolution expressing regret at losing the Chancellor, and deep appreciation of the honour which he has conferred on the University during his tenure of office.

The council passed the following resolution: "The council have heard with deep regret of the death of Sir William Thorburn, professor-emeritus of the University. They desire to record their sense of his great services as an administrator, a teacher, and an investigator, his eminence as a surgeon, and the wholehearted devotion with which he sacrificed himself in the service of his country. His sterling integrity inspired respect in all his colleagues and students. The council desire to convey to his relatives their profound sympathy with them in their loss."

The following appointments have been made:—Mr. F. Fairbrother, to be lecturer in chemistry; Dr. D. S. Sutherland, to be clinical lecturer in infectious diseases; and Dr. R. Marsden, to be hon. clinical lecturer in tuberculosis.

MR. W. H. ALLEN, past-vice-president of the Institution of Mechanical Engineers, has presented to the Institution the sum of 1000*l*., and has desired the council to select a suitable student or graduate to receive this grant, in three annual instalments, at Trinity College, Cambridge. Applicants should preferably be between 20 and 25 years of age, and must be able to satisfy the council that they possess such educational qualifications as will ensure that they would derive the maximum possible benefit from an honours course in engineering (Mechanical Science Tripos) at Cambridge. Preference will be given to an applicant who has had some practical workshop training. Applicants must be prepared to go into residence at Cambridge in October 1923. Applications should be made on a form to be obtained from the secretary of the Institution, and must be returned not later than May 1.

THE Ministry of Agriculture and Fisheries announces that a number of scholarships under the scheme approved last year for establishing scholarships and maintenance grants for the sons and daughters of agricultural workmen and others are offered for award for the session commencing in October next. The scholarships are provided out of the special fund for agricultural development voted by Parliament under the Corn Production Acts (Repeal) Act, 1921. They are of three kinds: Class I. scholarships, tenable for three years at Oxford, Cambridge, or other Universities, enabling students to attend degree courses in agriculture; Class II. scholarships, tenable for two years, at certain university departments of agriculture and agricultural colleges; and Class III. scholarships, tenable for one year at farm institutes and similar institutions. Candidates for Class I. and Class II. scholarships must be at least 17 years of age on June 30, 1923, and must satisfy the selection committee that they have reached a sufficiently high standard of education to derive educational benefit from the courses of instruction. For Class III. scholarships candidates will be required to furnish evidence of their acquaintance with practical agriculture, and they must be at least 16 years of age on June 30, 1923. Applications should be lodged with the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1, not later than May 14.

Societies and Academies.

LONDON.

Royal Society, March 22.—L. T. **Hogben** and F. R. **Winton**: The pigmentary effector system. III.—Colour response in the hypophysectomised frog. After complete removal of the pituitary gland, the melanophores remain permanently contracted, even when the frogs are exposed to conditions which are optimum for darkening of the skin; they can be made to expand by pituitary extract, but the animals regain pallor under conditions which invariably produce darkening in the normal or partially hypophysectomised (anterior lobe alone) frog. The minimum dose of pituitary extract for melanophore expansion was compared in normal and pituitaryless frogs. The experiments provide evidence that: (1) the rhythm of colour change in normal life is correlated with fluctuating amounts of pituitary secretion, and (2) direct nervous influences do not play a significant rôle in co-ordinating pigmentary responses in Amphibia.—H. R. **Hewer**: Studies on amphibian colour change. The presence of "frayed" ends to processes and isolated granules and irregular edges to the concentrated mass of granules precludes any theories postulating amœboid movement of cell processes. This is supported by (1) irregular movements of the granules; (2) slight massing of granules towards tips of processes in dispersed phase; and (3) stained sections of skin. Adult *Rana temporaria* respond, similarly to other Amphibia, to factors of normal environment. Dryness and light background cause concentration; moisture and dark background dispersion. Low temperature causes dispersion and medium temperature concentration. Higher temperatures appear to have an intermediate effect. Neither nitrogen nor hydrogen produced any effect during three hours; carbon dioxide did not affect colour before proving toxic; oxygen produced concentration in melanophores; chlorine changes melanin granules to a red colour.—J. **Walton**: On Rhexoxylon, Bancroft: a Triassic genus of plants exhibiting a liane-type of vascular organisation. The genus Rhexoxylon was instituted in 1913 for a fossil stem from South Africa. The evidence given by certain structural details was in favour of attributing it to the Palæozoic group of polystelic arborescent plants, the Medulloseæ. The study of additional specimens from South Africa shows that the organisation of the vascular system resembles very closely that of certain modern South American Lianes, especially in the anomalous methods of secondary thickening of the axis. Histologically, the secondary wood of Rhexoxylon resembles that of the group Dadoxyla, characteristic of the southern botanical province during the latter part of the Palæozoic era. Possibly Rhexoxylon, as a specialised ecological type, bore much the same relation to the gymnospermic Dadoxylon stock as the modern Liane bears to the angiospermic group at the present day, and the occurrence of an anomalous type of vascular system in the modern Liane is an example of a repetition, in a distinct phylum, of a specialised organisation evolved in Palæozoic times. The fossil stem *Antarcticoxylon priestleyi* Seward, from South Victoria Land, Antarctica, has some of these peculiarities, and its occurrence in the Beacon Sandstone Series of Antarctica points to a probably close relationship between portions of this series and the Stormberg Series of South Africa, from which came the majority of specimens of Rhexoxylon.—G. **Hewett**: The Dusuns of British North Borneo. The Dusuns themselves claim descent from the Chinese who settled in North Borneo. The general political conditions in Asia during the thirteenth century led to the invasion of North Borneo by Kublai Khan. The Bruni tribute was transferred from Majapahit to China, and the Chinese acquired the throne of Bruni. The Bruni government based its claim to the whole territory of North Borneo on the marriage of Sultan Akhmed to the Chinese daughter of Ong Shin Ping, who was in all probability the occupant of the Bruni throne at the time. The Chinese occupation and development probably lasted some four hundred years.—M. **Tribe**: The development of the hepatic venous system and the postcaval vein in the Marsupialia. The development of the hepatic veins is subject to variation. Two venous rings of vitelline origin are transformed into a spiral vessel encircling the gut. In most genera the left allantoic vein becomes the more important and in some genera it anastomoses with the spiral vessel. The mesenteric vein is probably derived, in part, from the caudal venous ring. The postcaval is derived from three sources. The postrenal section takes origin from the paired supracardinal plexus, the renal section from the subcardinal veins, the hepatic and prehepatic sections from the vitelline veins. The azygos and lumbar veins, and the suprarenal sinusoids, are derived from the supracardinal plexus. The left suprarenal vein is the persistent left subcardinal vein.—J. **Gray**: The mechanism of ciliary movement. III.—The effect of temperature. Between 0° and 33° C. the speed of the cilia on the gills of Mytilus increases with a rise in temperature, although the amplitude remains normal. Between 34° and 40° C. there is a marked falling off in the amplitude of the beat, followed by a reduction in speed. At 40° C. the cilia come to rest in the relaxed position. At 45° C. the cilia occupy the contracted position. The temperature coefficient of movement between 0° and 32·5° C. varies from 3·1-1·92. High temperatures have a destructive effect on individual cells of the epithelium. In well aerated tissue the oxygen consumption is directly proportional to the speed of the beat between 0°-30° C. At about 30° C. the initial oxygen consumption is not maintained, due to the disintegrative effect of the temperature on the epithelium. The effect of temperature on the activity of cilia is closely parallel to its effect on cardiac muscle.—E. **Ponder**: The inhibitory effect of blood serum on hæmolysis. The hæmolytic action of saponin is inhibited by the proteins of serum, and also, to a lesser extent, by the cholesterol. The action of the bile salts is inhibited by the proteins, and by the lecithin of the serum. The inhibitory power is fairly constant in man and animals, is altered by drying the serum, and is affected by bacterial action. A quantitative study of the inhibition produced by serum shows inhibition is probably due to the formation of a loose compound between the proteins of the serum and the hæmolytic agent. The inhibitory effect of hæmoglobin on hæmolysis produced by saponin and bile salts is considered. Probably the reaction which takes place between saponin or bile salts and red cells is a chemical one of the first order.

Royal Anthropological Institute, March 13.—Mr. H. J. E. Peake in the chair.—Miss M. Edith **Durham**: "Bird Men" and kindred customs in the Balkans. On the western side of the Balkan peninsula a considerable part of the population still identifies itself with birds. Thus the Albanians call themselves Shkypetars, and derive the word from Shkyp, an eagle, and regard the killing of an eagle as unlucky. In Montenegro also there is a strong bird tradition. Here it is the "soko," the falcon. Officers address their

men as "my falcons," and Montenegrins hail each other as falcons. In the traditional ballads of the people the falcon appears as the messenger. Between the popular hero, Marko Kralyevitch, and the falcons there exists a very great friendship. In other ballads the hero actually refuses to kill a falcon on the ground that it is kin to him, and in yet another the Tsar's daughter is with child by a "bird man," who is a falcon by day and who dies when his wings are taken from him, killed by the jealous Vilas who, in their turn, fly about in the guise of swans. The falcon and the swans dwell on the mountains where the sun rises, and magic lights herald their coming and going. The tale is obviously the remains of some ancient beliefs about the sun and the birds and recalls the quaint bronze bird chariots of the sun, found at Glasinatz in Bosnia. Ballads also describe warriors of the Middle Ages dressing themselves up with eagle's tails and wings, and a print from a book on Turkey by Nicholas de Nicolay (1568) shows such a warrior. Plume-wearing is extinct, but in the Eagle dance of the Montenegrin he leaps high off the ground, flaps his arms, and yells.

PARIS.

Academy of Sciences, February 26.—M. Albin Haller in the chair.—The president announced the death of E. Ariès, corresponding member for the section of mechanics.—André **Blondel**: The calculation of the forced oscillations of an electrogenic group (or of an analogous apparatus) turning with a constant mean velocity, but submitted to periodic variations of the motor couple at the same time as an elastic resisting force variable with the angle of deviation.—M. Louis Gentil was elected a member of the section of geography and navigation in succession to the late M. L. Favé.—Boris **Delaunay**: The geometrical interpretation of the generalisation of the algorithm of continued fractions given by Voronoï.—Maurice **Lecat**: Expression of the most general determinants of a matrix as a function of the sections.—C. E. **Traynard**: Surfaces of the fourth degree with fifteen double points and singular Abelian functions.—René **Lagrange**: Varieties with zero total torsion in Euclidian space.—Stanislas **Millot**: A criterion of the probable value of certain experiments.—J. **Grialou**: The rotational, but permanent, movement of liquids possessing viscosity, when the trajectories are plane and vertical.—C. **Flammarion**: The increase of brightness of the star β Ceti. A sudden increase in the brightness of this star was notified on February 13 by Mr. Abbott from Athens. This has been confirmed by observations at Juvisy by the author.—Emile **Belot**: The collective and discontinuous evolution of stars and nebulæ.—M. **Holweck**: The optical properties of X-rays of great wave-length. Experimental evidence has been obtained of the diffraction of X-rays of a minimum wave-length $\lambda = 47$ Å (effective wave-length $\lambda = 60$ Å approx.). Evidence of the reflection of X-rays by a polished bronze surface is also given.—G. **Laville**: The propagation of electromagnetic waves, maintained along two parallel wires. The theories of Kirchhoff and Lord Kelvin appear to explain the phenomena of propagation as exactly as the more complicated theories of Sommerfeld and M. Mie.—V. **Ylöstalo**: The measurement of high-frequency coefficients of self-induction.—H. **Copaux** and Ch. **Philips**: The heat of oxidation of glucinum. A correction of an earlier result; the new figure is 131·3 calories in place of 151·5 calories.—Paul **Riou**: The velocity of absorption of carbon dioxide by ammoniacal solutions. Curves are given showing the influence of additions of ammonium chloride, sodium bicarbonate, and sodium chloride to the solution, and of changes of temperature.—L. J. **Simon**: The action of methyl sulphate and of potassium methyl sulphate on monobasic organic acids in the absence of water. The interaction of anhydrous organic acids with these substances in certain cases may be used with advantage for the preparation of methyl esters.—A. **Roche** and V. **Thomas**: Researches on picryl sulphide. Study of the binary mixture: tolite-picryl sulphide. This explosive was extracted from German bombs: it is very stable and stands a compression of 500 kilograms per square centimetre without losing its property of detonating.—Raymond **Delaby**: The preparation of some ethers and glycidic derivatives of alkyl glycerols.—Y. **Milon**: The fauna and age of the carboniferous limestone of Saint-Segal (Finistère).—Jean **Piveteau**: The morphology of the scapular arc of the Permian reptiles of Madagascar.—Methodi **Popoff**: The respiratory system of plants. According to the generally accepted view the respiration of plants is confined to the leaves. This view leads to difficulties, and it is suggested that plants have a respiratory system presenting analogies, from the physiological point of view, with the respiratory system of animals.—Marcel **Mirande**: The proteo-lipoid nature of the sterinoplasts of the white lily. By the application of various microchemical tests the central body of the sterinoplasts has been proved to be of a lipoid nature, covered with a thin external layer of proteid material.—P. **Delauney**: New researches relating to the presence of loroglossin in native orchids. Loroglossin has been isolated, up to the present, from 17 species of native orchids belonging to five different genera.—Paul **Becquerel**: Observations on the necrobiosis of plant protoplasm with the aid of a new reagent. The reagent consists of methylene blue (2 parts), Bismarck brown (1 part), and neutral red (1 part) in aqueous solution ($\frac{1}{100}$). The death of the cell is accompanied by definite colour changes in the parts stained by this reagent.—G. L. **Funke**: Biological researches on plants with creeping stems.—Marc **Fouassier**: The influence of copper on the lactic fermentation. The minute traces of copper dissolved by milk in contact with that metal have a distinctly retarding influence on the growth of the lactic organism.—A. **Desgrez** and J. **Meunier**: The mineral elements of the blood.—L. **Cuénot**, R. **Lienhart**, and M. **Mutel**: Experiments showing the non-heredity of an acquired character.—Ed. **Lesné** and M. **Vaglianos**: The utilisation by the organism of the C vitamins introduced through the parents. From experiments on rabbits the authors conclude that it does not matter whether the C vitamins are introduced by ingestion or by injection, the beneficial effect is the same in either case.—A. **Pézard**, Knud **Sand**, and F. **Caridroit**: The experimental production of bipartite gynandromorphism in birds.

March 5.—M. Albin Haller in the chair.—G. **Urbain** and A. **Dauvillier**: The coexistence of celtium (element 72) and the yttria earths. The view of Coster and Hevesy regarding the improbability of element 72 being associated with the rare trivalent earths is said to be negatived not only by the work of the authors but also by the discovery of this element by Goldschmidt and Thomassen in malakon and in alvite.—Charles **Moureu** and Charles **Dufraisse**: Auto-oxidation: attempt to explain the mechanism of anti-oxygenisers.—André **Blondel**: Elementary calculations of the couples damping alternators with a forced regime in the theory of two reactions, when the resistances of the armature are neglected.—C. de la Vallée **Poussin**: Quasi-analytical

functions with real variables.—Ph. **Glangeaud**: The earthquake of October 12, 1922, in the Creuse and the Limousin, and some earthquakes in the north-west of the Central Massif. A map of the district over which the shocks were felt is given, showing also the lines of the faults in the geological strata. These earthquakes in the Central Massif are due to slipping along the old lines of the faults.—M. Gabriel Bertrand was elected a member of the section of chemistry in the place of the late H. Georges Lemoine. —Georges **Darmois**: The local integration of the equations of Einstein.—F. **Defourneaux**: A category of polynomials analogous with electrospherical polynomials.—N. **Abramesco**: The auto-generation of curves.—Henri **Milloux**: The growth of integral functions of finite order and their exceptional values in the angles.—Kyrille **Popoff**: The pendulum of variable length.—J. **Haag**: The interior problem of Schwarzschild, in the case of a heterogeneous sphere. —B. **Salomon**: The gryoscopic analogies of synchronous and asynchronous electrical machines and the transposition into mechanics of certain diagrams of electrotechnics.—MM. **Huguenard, Magnan,** and A. **Planiol**: An apparatus giving the instantaneous direction of the wind. This is a modified compensated hot-wire anemometer. By using this and the compensated hot-wire instrument for measuring wind velocity, both the instantaneous direction and velocity of the wind can be recorded on the same chart. Examples of such records are reproduced, and their bearing on problems of flight without motors indicated.—Jean **Chazy**: A correction derived from the theory of relativity to the Newtonian time of revolution of the planets.—J. Ph. **Lagrula**: Test of the rapidity realisable in equatorial measurements of small planets with a telescope provided with a photo-visual comparator and some additional accessories.—J. **Guillaume**: Observations of the sun made at the Lyons Observatory during the fourth quarter of 1922. The results of the observations taken on 61 days during this quarter are summarised in three tables showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—Henri **Béghin** and Paul **Monfraix**: A new gyrostatic compass. This instrument, composed of a system of three gyrostats, has been specially designed to neutralise the deviations produced by the motion of the ship.—F. W. **Klingstedt**: The ultra-violet absorption spectra of the cresols.—A. **Dauvillier**: The high frequency spectrum of celtium. Reply to a criticism by D. Coster and G. Hevesy.—André **Charriou**: The removal of acids from solution by precipitates of alumina. A study of the removal of chromic acid by aluminium hydroxide, and of the means of purifying the precipitate by washing with suitable reagents.—R. **Locquin** and Sung **Wouseng**: The preparation of various pinacones by the action of alkyl magnesium compounds on some α-hydroxy-methyl ketones. Details of a generally applicable method for preparing bitertiary α-glycols of the type $RR'C(OH)—C(OH)R''(CH_3)$.—Pauline **Ramart**: A molecular transposition in the pseudo-butyl-diphenylcarbinol series. A study of the compounds produced by the action of acetic anhydride and acetyl chloride upon the alcohol $(C_6H_5)_2 . C(OH) . C(CH_3)_3$.—Emile **André**: The separation of methyl oleate and methyl linoleate by fractional distillation. The separation is difficult, owing to the tendency of the linoleate to form polymers.—A. **Mailhe**: The decomposition of the aryl formamides. A new method of preparation of substituted ureas. The vapours of formanilide passed over finely divided nickel at 400°-410° C. give some aniline and diphenylurea. The formotoluides behave similarly.

—Henri **Longchambon**: The study of the spectrum of the triboluminescence of some substances. Crystals of tartaric acid when broken give a band spectrum of nitrogen similar to that obtained from sugar. Crystals of cadmium sulphate, uranium nitrate, and fluor spar also show nitrogen bands. The light from the uranium salt, which has a colour differing from the other, shows the four green fluorescence bands of uranium nitrate.—E. **Schnæbelé**: The granites of the Champ du Feu (Vosges).—Léon **Bertrand** and Antonin **Lanquine**: The co-ordination and origin of the Pyrenees-Provençal structural units in the south-west of the Maritime Alps.—Pierre **Bonnet**: The tectonic relations of the gneiss and coal measures in the northern Morvan.—Henry **Joly**: The constitution of the Jurassic at Torrelapaja and Bordejo (Celtiberic chain, provinces of Saragossa and Soria, Spain).—E. **Bénévent**: The mistral on the coast of Nice. The freedom of Nice from the mistral is not due to its sheltered position, but to its situation with respect to the trajectories of the barometric minima.—Joseph **Lévine**: Triatomic hydrogen and meteorological depressions.—J. **Beauverie**: Influence of the rainfall during the "critical period" of wheat on the yield. Provided the rainfall during the "critical period" is below a certain amount, the yield of wheat is roughly proportional to the rainfall. —A. A. **Mendes-Corrêa**: The proportions of the limbs in Portuguese. The Portuguese, from the point of view of the proportions of their limbs, are of a clearly European type.—Henri **Piéron**: The propagation of luminous stimulation of the retina to the cerebral outer layers.—Marc **Romieu**: The histological study of the testicle of *Orthagoriscus mola*.—R. **Hovasse** and G. **Teissier**: Peridinians and Zooxanthelles.—C. **Levaditi** and S. **Nicolau**: The filtration of neurotropic ultravirus through collodion membranes. The virus of rabies, encephalitis, herpes, and neurovaccine can be filtered under pressure through collodion membranes. The filtrates vary in toxic power; not only from one membrane to another, but also according to the nature of the virus.

Official Publications Received.

Report of the Commissioner of Education for the Year ended June 30, 1922. Pp. iii+32. (Washington: Government Printing Office.)

Report of the Marlborough College Natural History Society (founded April 9th, 1864) for the Year ending Christmas, 1922. (No. 71.) Pp. 72+3 plates. (Marlborough.)

FACULTY OF MEDICINE.

(Associated with the General and Queen's Hospitals for Clinical Teaching.)

SCHOOL OF DENTISTRY.

(In connection with the Birmingham Dental Hospital.)

The Summer Session opens on Tuesday, April 24, 1923.

The University grants Degrees in Medicine, Surgery, and Public Health, and a Diploma in Public Health; also Degrees and a Diploma in Dental Surgery.

The Courses of Instruction are also adapted to meet the requirements of Students preparing for the Examinations of other Universities and Licensing Bodies.

For Prospectus and further information apply to

WILLIAM F. HASLAM, F.R.C.S.,
Dean.

UNIVERSITY OF ABERDEEN.

VACATION COURSE, JULY 16-27, 1923.

SHORT COURSES BY PROFESSORS AND LECTURERS.

Group I. LITERARY AND ARTISTIC STUDIES, including: Present-day Germany; Recent Advances in Education; The Study of Words; Celtic Literature; Public Speaking; Recent Advances in Palæography.

Group II. SOCIAL AND HISTORICAL STUDIES, including: The Economic Evolution of the XIXth Century; The Settlement of St. Columba in Iona; The Call of John Knox to Reformed Ministry, at St. Andrews; Scottish Civilisation in the Early Centuries, A.D.; Cosmogonies, Old and New; Recent Excavation in Palestine; The Chapel, King's College; The Law of Insurance; Johann Sebastian Bach; Bach's Original Hymn Tunes, illustrated by a choir of voices.

Group III. SCIENCE, including: Evolution of a Land Flora; Bio-Chemistry; Modern Science and Garden Craft; The Applications of Meteorology to Aviation, Gunnery, etc.; Public Health; The Nervous System of Man; Sidelights on Human Disease from the Comparative Pathology Standpoint; Some Recent Advances in Physiology; The Hive Bee in Health and Disease; Recent Progress in Parasitology; Catalysis and its Industrial Application.

The lectures will be given in the forenoons.
Historical and Scientific Excursions will be arranged for the afternoons.
Fee Two Guineas for the whole Course; One Guinea for a week.
For further particulars apply to the SECRETARY to the UNIVERSITY OF ABERDEEN.

UNIVERSITY OF LIVERPOOL.

Session 1923-1924.

FACULTY OF ENGINEERING.

Dean—Prof. T B. ABELL, O.B.E., M.Eng., R.C.N.C., Ret., M.Inst.N.A.

Prospectus and full particulars of the following may be obtained on application to the REGISTRAR: Engineering, Thermodynamics of Heat Engines, Strength of Materials, Electrical Engineering, Civil Engineering, Naval Architecture, Metallurgy, Geology, Marine Engineering, Design and Drawing, Refrigeration, Mathematics, Physics, Chemistry.

BIRKBECK COLLEGE.

(UNIVERSITY OF LONDON.)

Principal—GEORGE SENTER, D.Sc., Ph.D., F.I.C.

EVENING COURSES for the Degrees of the University of London in the Faculty of Science and for the Geography Diploma.

Facilities are also provided during both day and evening for Post-Graduate and Research Work.

Calendar, 1s.; by post, 1s. 5d. Prospectus free.

For full particulars, apply to the SECRETARY, Birkbeck College, Fetter Lane, E.C.4.

APPOINTMENTS BOARD

OF THE

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON, S.W.7.

EMPLOYERS requiring men who have received a thorough training in Science and Technology, and who are Diplomates or Associates of the Imperial College, or of one of its three constituent Colleges, are asked to make use of the services of the Board. No fees.

The Imperial College includes The Royal College of Science, The Royal School of Mines, and The City and Guilds (Engineering) College. The Associates of the Colleges receive thorough training in Science and Technology, including Aeronautics, Applied Optics and Optical Engineering, Biology, Chemical Technology, Chemistry (all branches), Engineering (all branches, including Metallurgy, Mining, Mining Geology and Oil Technology), Geology, Mathematics and Mechanics, and Physics.

TUITION BY CORRESPONDENCE

Rapid preparation by highly qualified tutors for

MATRICULATION,
Intermediate and Final B.A. and B.Sc.,
OXFORD AND CAMBRIDGE LOCALS.

Single subjects may be taken:—Latin, Greek, Hebrew, French, Mathematics, Chemistry, Logic, etc. For terms address—

Mr. J. CHARLESTON, B.A. (Hons. Oxon. & Lond.),
14 Elsham Road, Kensington, W.14.

BATTERSEA POLYTECHNIC

LONDON, S.W.11

Award of Tate Scholarships for Session 1923-24.

The examinations for the award of SCHOLARSHIPS in ENGINEERING, SCIENCE, and DOMESTIC SCIENCE, will be held on Tuesday, June 5, 1923, and the succeeding days. The scholarships vary in value from £20 to £30 per annum with free tuition, and are tenable for two or three years.
Last day of entry April 21, 1923.
Full particulars on application to the PRINCIPAL.

TO SCIENTISTS AND RESEARCH STUDENTS.

THE INTERNATIONAL BIBLIOGRAPHICAL SERVICE BUREAU,

employed by British Government Departments, University Professors, etc., supplies complete Continental and American bibliographies on any scientific, literary, or medical subject. Chemical work a speciality. Extracts made.
Headquarters: Vienna. English representative: "ALEXANDRIAN," 1A Longridge Road, Earl's Court, S.W.5.

UNIVERSITY OF LONDON.

The Senate invite applications for the UNIVERSITY CHAIR OF ANATOMY, tenable at St. Bartholomew's Hospital Medical College. Salary £1000 a year. Applications (12 copies) must be received not later than first post on April 16, 1923, by the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7, from whom further particulars may be obtained.

UNIVERSITY OF LONDON.

The Senate invite applications for the RAMSAY MEMORIAL CHAIR of CHEMICAL ENGINEERING tenable at University College. Full particulars may be obtained from the ACADEMIC REGISTRAR, University of London, South Kensington, London, S.W.7.

Problems of Tuberculosis.

IN the *Empire Review* for March Dr. Leonard Williams brings forward the perennial theme of the Spahlinger treatment of tuberculosis. This "treatment" has been the subject of extravagant and repeated press notices since 1914, and when it is shorn of its decorations, what does it amount to? Merely that M. H. Spahlinger has made, or his friends have made for him, a number of categoric statements, unsupported by proofs of the kind demanded in scientific work, that he can cure tuberculosis in man and animals. In a relatively small number of cases of consumption, clinicians have stated that the disease was arrested. Dr. Leonard Williams, an ardent supporter of M. Spahlinger, cites the communication of the latter to what he calls the "high-browed Paris Academy of Sciences." This communication (1921, t. 172, p. 494) occupies exactly one page and four lines, and is a reiteration of former statements without any evidence whatsoever that they are correct or of essential scientific value.

Dr. Leonard Williams also quotes April 28, 1914, as memorable in the history of tuberculosis, for on that day Prof. Letulle presented to the French Academy of Medicine a communication entitled "Traitement de la tuberculose par la méthode Henri Spahlinger." In the *Bull. de l'Acad. de Méd.* (1914, 3. s. t. 71, p. 610) we find that the communication occupies exactly eighteen lines, and was a preliminary note addressed to the Academy by Dr. E. Lardy of Geneva and Drs. Colbeck and Leonard Williams of London. Prof. Letulle was charged to examine the note, but up to date we have been unable to find any further reference to the matter in the Bulletin, although Dr. Leonard Williams tells us that "the text of the communication was duly published and rapidly found its way into the lay press." It would be interesting to know where the full communication may be found.

M. Spahlinger's treatment is stated to be both antigenic and antitoxic, and he claims to have produced many different tuberculous toxins by a method not published. The process is a long one, and the cost of production we are told is high, involving prolonged treatment of large numbers of cattle. The only other tuberculous problem referred to by Dr. Leonard Williams is really a panegyric on the work of Calmette. We are told that the "campaign against tuberculosis will never make any serious headway until the disease is attacked at the source. That source is the tuberculous cow." This may be Dr. Leonard Williams' opinion, but it is entirely opposed to the conclusions reached by the arduous experimental efforts of a generation of accurate workers. W. B.

Archæological History.

(1) *Die Franken und Westgoten in der Völkerwanderungszeit.* By Nils Åberg. (Arbeten utgifna med understöd af Vilhelm Ekmans Universitetsfond, Uppsala, 28.) Pp. viii+282+9 kartes. (Uppsala: A.-B. Akademiska Bokhandeln; Leipzig: Otto Harrassowitz; Paris: Libr. Honoré Champion, 1922.) 15 Kr.

(2) *The Bronze Age and the Celtic World.* By Harold Peake. Pp. 201+14 plates. (London: Benn Bros., Ltd., 1922.) 42*s.* net.

ARCHÆOLOGICAL method has made three principal advances hitherto. Early attempts to explain similarities and diversities of form and style in human handiwork were put on a scientific basis in Germany by Klemm (whose "Allgemeine Kulturgeschichte der Menschheit" appeared in 1843) and were re-interpreted on Darwinian lines by Pitt Rivers's "Principles of Classification" published in 1874; Kapp's "Grundlinien einer Philosophie der Technik," Semper's "Der Stil," and Hoernes' "Urgeschichte der Kunst" marking later refinements of this morphological criticism. Stratigraphical corroboration of evolutionary sequences thus indicated begins with examination of the Swiss lake-dwellings by Keller, Troyon, and others, the word *Kulturschicht* first appearing in an excavation report of 1855. The spade-work of Ramsauer at Hallstatt from 1862, of Warren and Wilson at Jerusalem from 1867, and of Schliemann at Troy from 1871, are notable early dissections of long-inhabited ground; and the developed technique of this kind of stratigraphy may be studied in Petrie's "Methods and Aims in Archæology."

The two books now under review approach archæological problems from yet another point of view. Even casual finds are at all events found *somewhere*. They can be plotted on a map; and when these plottings are sufficiently numerous, and their geographical distribution begins to be apparent, regions of occupation by this or that phase of culture may be defined, and the spread or shrinkage may be inferred of the people who practised each kind of handiwork which the finds reveal, and felt the needs which the craftsmen of each generation were there to satisfy. Thus, as Rostovtseff says of his own study of "Iranians and Greeks in South Russia" (Oxford, 1922), "we are gradually learning how to write history with the help of archæology." The method is precisely that of the staff-officer who establishes an enemy's order of battle from cap-badges and scraps of local newspaper, and estimates its artillery value from the splinters of his shells; and the value of archæological training was demonstrated on every front in the recent war.

Obviously this kind of antiquarian geography has had to wait until the finds themselves were sufficiently numerous; until they had been sufficiently announced, in museum catalogues and publications in detail; still more, until geographers (and, let us add, geologists) had accustomed their archæological colleagues to regard their proper "fossils" from the new point of view, looking not only "to the hole of the pit whence they were digged" but also "to the rock whence they were hewn."

(1) Dr. Åberg's work on the stone age culture of northern Europe, and on the first age of metal in the Iberian peninsula, is sufficient guarantee for scientific scholarship of the first order; his book on "East Prussia in the Migration Period" is an original contribution to one of the darkest phases of European history; and his present monograph on the "Franks and Visigoths in the Migration Period" is of the same fine quality. Naturally, his treatment of the material varies. Visigothic handiwork must be won by travel and research in local museums and private collections, and we are here still among the pioneers. But Frankish antiquities have been copiously published and studied, and the casual finds have been supplemented by systematic investigation of whole burial grounds, so that "sequence-dating" supplements the comparison and affiliation of types, and facilitates interpretation of regional surveys. As most of the work has been done hitherto by French archæologists, and from the point of view of the invaded regions, the principal need was now to look at the whole matter from the other side. As Rostovtseff puts it, in a parallel case, "I do not regard South Russia as one of the provinces of the Greek world . . ." but "as always an Oriental land," so Dr. Åberg might say that he does not regard the Franks as one of the peoples who intruded upon Gallo-Roman civilisation, but as always a Teutonic people. The result is an interpretation not only of the Frankish finds of the west, but also of all the congruous material east of the Rhine, north of the Alps, and so far afield as Hungary and Scandinavia, and also in Lombardy and beyond, as contributions to the narrative of a progressive Frankification (so to speak) of indigenous Teutonic culture through the instrumentality of those peoples of Teuton origin who had most completely appropriated the west-land civilisation which they mastered politically.

Thus, in a sense which will be a revelation to many, *Gallia victa victorum cepit*: or as Dr. Åberg puts it (p. 15), "the Franks in Gaul were influenced indeed, like the Goths in Italy, by Roman culture, but in contrast with them, they retained their power in spite of their loss of Teutonic quality, thanks to the maintenance of intercourse along the lines of communication

with the heart of Germany. Consequently there was no gulf here between Germanic and Roman, but a gradual transition. Roman organisation pressed slowly eastward. . . . The focus of development, which in Merovingian times had been mainly Gaul, shifted over in Carolingian times on to German soil. Here came about the last amalgamation of Roman and Germanic which is the foundation of modern Europe. Only Scandinavia still stayed long outside this development, as a last remnant of ancient Germany, and a wound in the side of Europe which was hard to heal."

For the stages of this revolution in social and political structure Dr. Åberg offers us as testimony not edicts or charters, nor a *cursus honorum* such as has revealed the spirit and the structure of imperial Rome, but the mute eloquence of hundreds of brooches and buckles, of ingenious design, intricate ornamentation, and accurately plotted distribution. His inventory of type-specimens occupies 42 pages, and his nine maps of the principal phases which he has been able to distinguish are models of this kind of interpretation. His first two chapters, occupying only forty pages, trace the outlines of the whole inquiry, and summarise the course of events before the opening of the fifth century, at which his proper study begins. These and the subsequent later review of Merovingian influence east of the Rhine are what will chiefly interest the historian; the remainder of the book, with its ample and well-executed illustrations, concerns rather the student of design and of the transference of decorative motives from one repertoire to another.

The account of the Visigothic occupation of Spain and Portugal (pp. 206-240) is more tentative, because (as already noted) the material is scanty and inaccessible, and, to judge from the specimens which are figured here, less instructive as to the movements of Germanic peoples in this region. Provisionally, Dr. Åberg groups all Germanic antiquities from this area as "Gothic," reserving till a later stage the possibility of assigning some types to particular peoples.

A word should be added to congratulate the Vilhelm Ekmans Fund at Uppsala on having produced so learned, valuable, and well-appointed a volume at the rate of less than three farthings per page.

(2) Mr. Peake's book is of a different quality. Spaciously printed, and well bound—and we must add, more than adequately priced at 2½d. per page—it is little more than a reprint of a course of six University lectures, with acknowledgments of the principal sources of printed information, the bare minimum of outline diagrams, and far less than the due minimum of distribution maps. The author disarms criticism when he declares his purpose to be "not so much to record evidence as to interpret it, to restore the main features of early history than to describe archæological remains." It is, in fact, an essay rather than a formal treatise. It covers very wide ground, from a preliminary survey of the pre-Celtic continent—Nordic, Alpine, and mixed Mediterranean stocks, partially brought into economic relations by slow breach of natural barriers, especially forest and mountain, and by the pervasive wiles of the "prospectors"—to the problem of the replacement of bronze by iron for cutting-weapons, and the superposition of "P-Celts" upon "Q-Celts" and of other P's upon other Q's.

To be proficient at all points of such a programme would be a giant's task. Mr. Peake has read widely (though scarcely widely enough) and has thought independently and boldly; and his book is always readable and intelligible. Frequently his suggestions carry conviction; his mistakes are mostly of omission; and his summaries even of the most controversial matters are discreet and fair. Obsolete learning he is for the most part content to leave on one side, and where he feels obliged to review the course of inquiry, as in the chapter on the "Aryan Home," he knows how to select main turning-points, and distinguish the permanently suggestive idea from the transitory prejudices which advertised or obscured it at its inception.

The problem which Mr. Peake has set before himself is to compare the archæological evidence for reputed movements of peoples within peninsular Europe, from the end of the third thousand years B.C. to the beginning of the first, with the philological conclusions on the same subject derived from the relationships and distributions of languages. His conclusion, briefly stated, is that the distribution over Europe and its neighbourhood, of the series of types of so-called "leaf-shaped swords" of bronze, is such as to indicate successive eruptions of peoples armed with these swords, from the Hungarian plain into various adjacent regions and beyond them. Also that the disappearance of the later types of the series from Hungary itself and from surrounding districts may be so closely associated with the distribution of other swords, similar but derivative and made of iron, as to justify the inference that it was the aggression of the men of the iron swords that determined the retreat or disappearance of the users of "leaf-shaped" bronze blades. Lucky finds of typical swords in datable surroundings, and especially the discovery in Egypt of a sword of European type, about half-way down the morphological series, engraved with the name of King Seti II., who reigned only from 1209 to 1204 B.C., enable him to reckon the probable duration of the whole series of events, and to institute a very suggestive comparison of them with the movements of the two main groups of Celtic-speaking peoples,

from much the same area of origin around the middle Danube, into Western Europe and Britain, and of similar waves of "P-using" and "Q-using" immigrants into peninsular Italy, and probably also into Greece; though Mr. Peake is discreetly reserved in his treatment of these last.

Much of Mr. Peake's material is, of course, familiar; it is his courageous attempt to compare disparate series, and draw historical conclusions, which justifies his book; and it will be found full of suggestive passages, even by those who will best appreciate the difficulties of his task and the defects of his equipment for it. It is eminently a book to be judged by its merits, not by its faults. It has omissions, but its main argument is clear and generally coherent; it has slips and some misapprehensions in detail, but they do not seriously detract from its cogency. Its central contribution to learning, the establishment of a morphological sequence among the "leaf-shaped swords" by comparative study, not of their blades but of their hilts, is of considerable importance. This is a kind of work of which much more remains to be done: a similar essay on the fibulæ alone would probably lead to appreciable revision of the conclusions of Montelius and his contemporaries a generation ago, and would be the only conclusive test of the validity of Mr. Peake's inferences. It must also be noted here that even what has been attempted in this essay is but the first-fruits of the great inventory of the types of prehistoric implements, so long overdue, of which only the British section of the bronze implements has been systematically attempted as yet, by Mr. Peake himself and a British Association committee. Till such an inventory has been very greatly extended, and the distributions which it alone can reveal have been plotted and compared, prehistoric archæology can scarcely be said to have entered upon a truly scientific phase. It is one of the merits of any piece of work such as this essay, that it illustrates by example, even if also in some degree by anticipation, the value of such an addition to archæological equipment as the British Association's inventory is already proving itself to be.

Gelatin and Glue.

The Chemistry and Technology of Gelatin and Glue. By Dr. R. H. Bogue. (Mellon Institute Technochemical Series.) Pp. xi+644. (New York and London: McGraw-Hill Book Co., Inc., 1922.) 30*s*.

ANYONE who, in recent years, has had occasion to deal with the question of gelatin has been confronted at the outset with the fact that no adequate summary of the existing knowledge was available. An immense amount of information was widely scattered in the various scientific and technical journals of all countries, but it was so varied in character, and very often so contradictory, that the task of making a summary which was something other than a mass of apparently disconnected facts seemed almost hopeless. The pioneering work of Procter in England, which dealt chiefly with gelatin, and of Pauli in Austria, which was concerned with proteins in general, gave the first indication of the basis on which such a summary could be made; but the more recent work of Loeb in America has perhaps helped more than anything else towards a clarification of ideas. The work of Brailsford Robertson should also be mentioned, since he has collected a large amount of experimental data, although his theoretical conclusions are accepted by few.

The clarification of ideas has been chiefly confined to the physico-chemical treatment of the subject. The more purely chemical aspect of the question has not advanced much beyond the identification of the break-down products of gelatin, and the more or less satisfactory methods of estimating the percentages of the various kinds of combined nitrogen.

During the last few years American scientific journals especially have obtained a large number of papers on gelatin, which have been published by workers other than Loeb. Among the chief of these workers has been Dr. Bogue, and it is therefore not to be wondered at that, of three books on gelatin which have been announced in the American press for some time past, his is the first to be published. Dr. Bogue is research chemist for Armour and Company of Chicago—would that English gelatin firms were as wide awake in this respect as the American ones!—and is consequently in touch with the technological as well as with the more purely theoretical side of the subject. His book has therefore been awaited with interest by those who have to deal with gelatin, and they will not be disappointed, since the author has been eminently successful in correlating and summarising the enormous amount of material at his disposal, and in giving a clear and readable account of the subject. After an introduction dealing with historical and statistical considerations, the theoretical aspects of the subject are considered. These include the constitution of the proteins, the chemistry of gelatin and its congeners, the physico-chemical properties and structure of gelatin, gelatin as a lyophile and as an amphoteric colloid.

The author seems to have contented himself with giving only such literature references as are necessary for drawing up a connected account of the subject.

This was probably a wise course to adopt, since otherwise the book would have become very unwieldy, but it has meant that a number of important papers published in German journals are not mentioned. For example, Dr. Bogue is a great advocate of the fibrillar structure of gels, but no mention is made of similar views put forward by Moeller in a number of different papers in the *Kolloid Zeitschrift*. A lucid description is given of the various physico-chemical properties of gelatins and glues and the various theories are dealt with in detail. If anything, the author has not been sufficiently critical in describing the theories of Brailsford Robertson, who assumes a peculiar kind of dissociation which appeals neither to the organic nor to the physical chemist, and against which there is a mass of evidence accumulated by Pauli, Loeb, and others. Actually, Dr. Bogue attempts to modify Robertson's theory, so as to make it more in accordance with the work of Loeb, but the modified theory is still open to most of the objections raised against the original theory.

The second part of the book deals with the technological aspects of the manufacture, testing, chemical analysis, evaluation, uses and applications of gelatin and glue. The point of view taken is that of the chemist rather than that of the plant technologist, and this makes the appeal of the book all the greater to the student and investigator. In the chapter on the uses and applications of glue there is a section on glue-room economy and technology, which may be recommended for study to all users of glue on a large scale, so that increased efficacy, based on the application of scientific principles, may be attained in their workshops.

There is also a special chapter on water-resistant glues and glues of marine origin, which should be read in conjunction with the first report of the Adhesives Research Committee. An appendix deals more especially with the electrometric and indicator methods of determining hydrion concentrations.

Generally speaking, there is little which calls for criticism, except the curious statement made on p. 221 that acetic acid is an amphoteric substance because the hydrogen of its carboxyl group may be substituted by metals and the hydroxyl by chlorine (by the use of phosphorus trichloride). A few misprints, such as "existance" and "catinary," have been noticed, and the following statement on p. 141 requires revision: "but this does not follow for a continuous membrane that was semipermeable in the sense of being able to dissolve the solvent or medium of dispersion would likewise behave as an ultra-filter." Also, why should it be necessary to write "Anfangsdekrement" instead of "initial decrement"?

T. S. P.

Flora of New Zealand.

Die Vegetation der Erde. Sammlung pflanzengeographischer Monographien. Herausgegeben von Prof. A. Engler und Prof. O. Drude. XIV. *The Vegetation of New Zealand.* By Dr. L. Cockayne. Pp. xxiii + 364 + 2 maps + 65 plates. (Leipzig: W. Engelmann; New York: G. E. Stechert and Co., 1921.)

WITH the landing of Sir Joseph Banks and Dr. Solander at Poverty Bay on October 8, 1769, our knowledge of the flora of New Zealand commenced, but unfortunately the results of the labours of these two intrepid explorers have never been published, though the plates of the new plants were prepared at Banks's expense and the descriptions were drawn up by Solander. From this time onwards various expeditions, both English and French, reached New Zealand, making small collections, the results of which were published, but Sir Joseph Hooker's first volume of his "Flora Antarctica," published in 1847, must be regarded as the first comprehensive flora of these islands. As a result of the help received from many collectors, Hooker published his "Flora Novae Zelandiae" (1853–55), which truly marked a new era in the botany of New Zealand, but still little was known of the South Island alpine flora, and it is to Travers, Haast, Hector, and Buchanan that we owe a great deal of our knowledge of the flora of this region.

Sir Joseph Hooker again contributed to our knowledge of the flora in his "Handbook of the New Zealand Flora" (1864–67), undertaken at the instance of the Government of New Zealand, and since then the task has been fittingly and very ably taken up by New Zealand botanists, among whom must especially be mentioned T. Kirk, T. F. Cheeseman, D. Petrie, and L. Cockayne, the author of the valuable work under notice. Dr. Cockayne commenced his botanical work in 1887, and has continued his explorations with great assiduity and keen insight ever since. Becoming gradually more interested in ecology, the present volume, dealing with the vegetation of New Zealand in its many aspects and in relation to the varied plant associations, could not have been entrusted to more worthy hands. Nor could the subject have been more ably treated.

In an introductory chapter the history of our knowledge of the flora is detailed and the book is then divided up into four parts. The first part, as is proper in a treatise planned on ecological lines, deals with the physical geography and climate of the three main islands and of the outlying groups, the chapter on the climate and rainfall being contributed by Mr. D. C. Bates. It is unfortunate that the maps are sadly

deficient in the way of names and orographical details, both of which are essential for a proper appreciation of the work. Possibly the difficulty of publication so soon after the War, and also in Germany, may account for this blemish to a book which is remarkable in the excellence of its form and style, considering that author and publisher were at opposite sides of the world.

The second part naturally occupies the greater portion of the book, since it deals with the various formations or plant associations, and full details and excellent illustrations are given of the leading physiognomic plants and their growth forms. In the first section the sea-coast vegetation with the characteristic dune plants, salt meadow and coastal scrub, Olearia and Veronica associations, are described, and this leads to a discussion of the plant formations of the lowlands and lower hills, characterised by many peculiar endemic New Zealand plants. Among these the "Southern Beech" forests, comprised mainly of the different species of Nothofagus, are of great interest. Passing upwards through the grasslands or steppe, where the "Tussock" (Poa, Festuca, and Danthonia) associations flourish, the author naturally follows with an account of the vegetation of the high mountains. This is remarkable in that no less than 498 species of vascular plants are entirely confined to the mountains, but since many lowland plants are also found at high elevations, the alpine flora is found to number 945 species. Of these no less than 561 are endemic.

In Part III. the relationships of the New Zealand flora are fully dealt with, but it may be mentioned here that of this flora about 35 species belonging to as many genera have near relatives in subantarctic South America.

The vegetation of the outlying islands is then fully dealt with on the same lines as that of the main islands, and, in the subantarctic islands, it is shown that there are some 55 endemic, 123 New Zealand, and 32 subantarctic South American plants, nine of which are not found on the main islands of New Zealand.

The fifth section of this second part deals with the effect of "settlement" upon the plant covering of New Zealand and is by no means pleasant reading. The hand of man, his introduced animals and plants, have, in New Zealand as elsewhere, wrought irreparable destruction and modifications in the primeval and singular plant covering.

In the final part, Dr. Cockayne gives a brief but useful history of the flora from the Jurassic period to the present time, and lays stress on the subantarctic affinities both of the flora and fauna of New Zealand. Whether land connexions with an antarctic continent ever existed, or chains of islands linking the southern continents provided the bridge which enabled species to migrate to what is now S. America on one hand and Tasmania on the other, must ever remain a problem. Dr. Cockayne considers that the difficulty of transoceanic transit is too great to account for the affinities, and, no doubt rightly, inclines to the problematical bridge of land or islands in the dim past. Whatever may have been the origin of this interesting primeval flora, it is very satisfactory to note that the Government of New Zealand is taking all possible steps to preserve, so far as may be possible, its unique features.

Electrical Engineering.

Standard Handbook for Electrical Engineers. Prepared by a Staff of Specialists; Editor-in-Chief: Frank F. Fowle. Fifth edition, thoroughly revised. Pp. xviii+2137. (New York and London: McGraw-Hill Book Co. Inc., 1922.) 30*s*.

WE think that the volume under notice justifies its title as being a "standard" handbook. The general make-up and arrangement leave little to be desired. The whole field of electrical engineering is divided into twenty-five sections each complete in itself; these are all numbered and by special depressions on the edges of the pages any particular section is found at once. The index is good, the references being made to section and paragraph. The sections have all been written by well-known American engineers and physicists and have been brought carefully up to date; for example, the section on units is written by Kennelly, magnetic circuits by Karapetoff, illumination by Millar, and electric ship propulsion by Hobart.

We were momentarily surprised to learn from Prof. Kennelly that the M.T.S. (metre-ton-second) and the Q.E.S. (quadrant-eleventh-gram-second) systems had come into extensive use. This latter system, however, is only the international electromagnetic system used in electrical engineering. We were glad to see it definitely stated that the electric and magnetic constants of the ether should not be taken as pure numerics. The section on power transmission is very thorough and data are given which would be very difficult to find elsewhere. The twenty-fourth section gives the 1921 edition of the standards of the American Institute of Electrical Engineers. In connexion with the distortion of waves, we are sorry to see that they still call a certain very variable ratio the "deviation factor" of the wave. In defining the distortion of a wave it is necessary to take into account the phase differences as well as the magnitudes of the amplitudes of its harmonics. We notice also that a resistance coil, a choking coil, and an inductive coil are now called a resistor, an inductor, and a reactor.

The final section is on general engineering economics and will be of great interest to commercial engineers. It is stated that "profits" represent a return on the capital over and above the normal rate of interest. For example, if the difference between income and expenditure was 10 per cent. then assuming that 6 per cent. is the normal rate of interest on investments, the "profit" would be 4 per cent. Apparently in America there is no agreed theory of depreciation, the straight-line or simple interest method and the sinking-fund or compound interest method are both still used.

The references given include the best American and English authorities and are useful ones. We can heartily recommend the book. A. R.

Our Bookshelf.

The Yearbook of the Universities of the Empire, 1923. Edited by W. H. Dawson. (Published for the Universities Bureau of the British Empire.) Pp. xii + 692. (London: G. Bell and Sons, Ltd., 1923.) 7*s*. 6*d*. net.

THE latest edition of the Yearbook, revised and amplified, should be of the greatest help not only to those officially concerned in university administration, but also to all who are interested in the developments within the British Empire of higher and professional education. It is no small feat to compress within the cover of an easily handled (and well indexed) volume the essential details of the calendars of the sixty-six universities of the Empire. Mr. Dawson, who has edited the book for the Universities Bureau, has accomplished the task very creditably, and the abbreviations and other typographical devices to which he has had recourse do not in any way militate against intelligibility, and, so far as we have tested it, the information given is both accurate and adequate.

The appendices, which now run to more than 150 pages, contain some interesting information, not easily accessible elsewhere, regarding admission to the various professions and the qualifications necessary. A section on foreign universities gives some brief but useful particulars of the principal universities on the continent and also of the universities of the United States, including a list of the institutions approved by the Association of American Universities.

Mention should also be made of the information relating to the admission to universities in the United Kingdom of persons educated abroad, to scholarships and grants for research, and to the distribution of subjects of study among British universities. Particularly interesting is a table showing the numbers of students from overseas, which suggests that the resources of this country for postgraduate and other study are now being appreciated. The total number of such students is more than 4000. At London University alone there are 81 from Egypt, 336 from South Africa, 46 from Canada, 72 from the United States, and 335 from India.

The Microscopical Examination of Foods and Drugs. By Prof. H. G. Greenish. Third edition. Pp. xx + 386. (London: J. and A. Churchill, 1923.) 18*s*. net.

PROF. GREENISH'S volume stands alone as a modern English text-book of the subject, and it is a matter of considerable satisfaction that author and publisher combine to keep the work abreast of the times. In the new edition, the text has been carefully revised and brought up-to-date, but we are informed that the inclusion of additional matter has not been possible on account of the prevailing high costs of paper and printing. We hope that by the time a further edition is called for, a means will have been found to overcome this difficulty, if it should still exist.

The book is too well known to need detailed description, but for the benefit of new students and others we may mention that its special value lies in the fact that it furnishes detailed information regarding methods of investigation which have been developed during many years by an acknowledged expert in the subject. In work of this kind, prolonged and continuous experience is a *sine qua non* for accurate determinations, and the methods so fully and clearly set out in this handbook bear unmistakable evidence of such experience. The book is essential to all pharmacological laboratories and students, and we suggest that teachers of "pure" botany would find many hints as to methods and material which would be of assistance to them in obtaining fresh ideas for the scheme of practical work to accompany their histological lectures. If in a later edition it is decided to retain "silk" as a material for description, we suggest that space should be found for a somewhat fuller treatment of the subject, including a reference to the important results obtained by von Höhnel in his investigations of the different kinds of commercial silks.

The Analysis of Non-Ferrous Alloys. By Fred Ibbotson and Leslie Aitchison. Second edition. Pp. ix + 246. (London: Longmans, Green and Co., 1922.) 12*s*. 6*d*. net.

THE fact that a second edition of this text-book has been called for is evidence that it has been found useful by analysts. War experience has led to an enlargement of the field of non-ferrous alloys, and the authors have therefore added to the matter of the former edition an account of the analysis of alloys containing aluminium as their principal constituent, and also of those rich in nickel, such as cupro-nickel and nichrome. The light aluminium alloys form a particularly difficult class, and it has been found necessary to devote a special chapter to the separation of zinc and aluminium, the authors recommending the precipitation of zinc sulphide from alkaline solution or the electro-deposition of zinc. The otherwise excellent section on electrolytic analysis suggests that no cathodes other than platinum and mercury can be used successfully, but many laboratories now employ copper and nickel gauze cathodes with entire success; an important consideration when the cost of platinum is so high.

The subject of hydrogen sulphide precipitations is dealt with thoroughly, this being a matter on which it is most important to have a clear view of the conditions affecting precipitation. The newer organic reagents, such as cupferron, are not described.

The work may be thoroughly recommended to professional analysts as well as to students, the authors having a wide personal experience of the methods they describe, their views on the best methods of analysing difficult alloys being particularly valuable.

La Radiotélephonie. Par Carlo Toché. Pp. vi+98. (Paris : Gauthier-Villars et Cie, 1922.) 10 francs.

THE book under notice gives an interesting general description of the best and most modern methods of radiotelephony. It presupposes on the part of the reader an elementary knowledge of the subject and a general knowledge of science. It begins by describing the physiology of the voice, giving photographic records of voice vibrations obtained by Marage. It is interesting to note that oscillograms obtained of microphonic currents produced by speech are not so simple as those shown. The arc, alternator and valve methods of radiotelephony are next described, more stress being laid on the theory than on the history of the art. Due credit is assigned to the work done by the American Western Electric Co. A good discussion is given of the possibility of simultaneous communications in radiotelephony. The essential frequencies required for speech vary between 200 and 2000 per second, and the frequency of the carrier waves between 15,000 and three million per second. The author concludes that the maximum possible number of simultaneous communications is 1492. It has to be remembered that many of these waves have short wave-lengths and are therefore not suitable for long-distance transmission. For international and intercontinental systems the possible number would be much smaller. The number of possible radio-telegraphic systems with carrier waves is very much larger than the number of possible telephonic systems.

The Grammar of the Lamba Language. By C. M. Doke. (Published under the Joint Auspices of the University of the Witwatersrand, and the Council of Education, Witwatersrand.) Pp. ix+157. (London : Kegan Paul and Co., Ltd., 1922.) 6*s.* net.

IT is a pleasure to extend a welcome to this scholarly study of the Lamba language, not least on the ground that it is published under the auspices of the Witwatersrand University and Council of Education, and bears witness to the official interest now taken in native studies.

The Lamba language is spoken throughout the Ndola district of North-Western Rhodesia and in the south of the Katanga, this area lying in the centre of Bantu Africa. It is claimed to be the most primitive dialect of Bantu now extant, a view to which the author inclines on the ground of its strict adherence to rule and the great simplicity of its phonetics. Numeration is based upon the quinary system. The use of onomatopœia is very prevalent, and not only can all verbs be reduced to a monosyllable root, but they also appear to have evolved from onomatopœic sounds, adjectives and nouns representing a further stage in evolution. Lamba contains a number of loan words from Portuguese (the earliest), Swahili, English, and Dutch, as well as from other Bantu dialects. The days of the week, it is interesting to note, are taken from Chinyanja.

A Manual of Practical Anatomy : A Guide to the Dissection of the Human Body. By Prof. Thomas Walmsley. In 3 parts. Part 3 : The Head and Neck. Pp. viii+272. (London : Longmans, Green and Co., 1922.) 10*s.* 6*d.* net.

THE third part of Professor Walmsley's "Manual of Practical Anatomy" is devoted to the dissection of the head and neck, for which a period of about ten weeks is suggested. The usual order of dissection is adopted, the various regions and organs being treated separately, but without that strict confinement to region which is so confusing to the student when dealing with a structure which appears in different portions of the dissection. The instructions for the guidance of the dissector are clearly given ; the anatomical descriptions are complete and well illustrated by diagrams which the student is encouraged to label from his own specimen. The only defect in the book is that the index is not very complete. We are glad to observe that the nomenclature is in the British (Old) terminology. The book can be thoroughly recommended as a guide to the student in the dissecting-room.

Inorganic Chemistry : A Text-book for Schools. By E. J. Holmyard. Pp. x+560. (London : Edward Arnold and Co., 1922.) 6*s.* 6*d.*

MR. HOLMYARD has written what is really an excellent text-book for schools. The style is clear and the arrangement on the whole good, although the very late appearance of the halogen elements is perhaps not quite fair to their great activity and their participation in the lives of the other simple bodies. The historical notices, as might have been expected, are excellent, and they and a number of portraits of famous chemists add considerably to the interest of the book. We wish this book the full success it deserves.

The Handbook of Palestine. Edited by Harry Charles Luke and Edward Keith-Roach. (Issued under the authority of the Government of Palestine.) Pp. xii+295. (London : Macmillan and Co., Ltd., 1922.) 12*s.* net.

THIS is mainly a handbook of general information, but there are short chapters on the geology and natural history and a note on the flora. Forestry receives more attention. Meteorology is scarcely noticed. The sections on races and on archæology are fairly full. A folding sketch-map shows roads, railways and archæological features, but no relief. The handbook should prove of value to every visitor to Palestine, but it might be given a wider and more permanent value if the historical and scientific sections were extended.

The Radio Year Book, 1923 (First Year). Pp. viii+148. (London : Sir Isaac Pitman and Sons, Ltd., 1923.) 1*s.* 6*d.* net.

IT is intended to make this the Year Book of the new industry which is rapidly growing, owing to the great popular interest which is being taken in broadcasting. Section I. gives general information of use to radio amateurs. Section II. gives short and trustworthy articles on subjects of general interest in the working of radio apparatus, and Section III. gives information which will be useful to manufacturers and suppliers of the apparatus. The articles are by well-known experts, and the book should prove useful.

Letters to the Editor.

On Urbain's Celtium Lines.

IN a previous letter (NATURE, March 10, p. 322) we have shown that the optical spectrum of the new element hafnium, of atomic number 72, which was discovered a short time ago by Coster and Hevesy, does not contain any of the lines belonging to the characteristic spectrum ascribed by Urbain (*Comptes rendus*, t. 152, 1911, p. 141) to an element celtium belonging to the family of rare earths, which element was assumed by Dauvillier and Urbain (*Comptes rendus*, t. 174, 1922, pp. 1347 and 1349; NATURE, February 17, 1923, p. 218) to possess the atomic number 72.

Through an examination of the very careful measurements of the spectra of the rare earths published during the last few years by Eder, we have learned in the meantime that the greater part of Urbain's celtium lines have been observed by this author (*Wiener Ber.*, IIa, vol. 124, 1915) in the spectrum of a preparation of the rare earth element cassiopeium or lutetium. The discovery of this element (atomic number 71) was announced in 1905 by Auer von Welsbach, to whom the former name is due, while the name lutetium was proposed in 1907 by Urbain, who published at the same time the first list of lines of its optical spectrum (*Comptes rendus*, t. 145, 1907, p. 759).

In the table below we give the wave-lengths of the celtium lines from Urbain's paper, together with their relative intensities (by use of the numbers 2, 4, 6, and 8 instead of Urbain's notations: *moyenne, assez forte, forte, très forte*) and the corresponding wave-lengths and intensities from Eder's measurements of the cassiopeium spectrum, corrected to Rowland's scale.

Urbain's Ct Lines.		Cp Lines observed by Eder.		Urbain's Ct Lines.		Cp Lines observed by Eder.	
2459·4	2	2459·71	1	2885·1	4	2885·23	3
2469·3	2	..		2903·9	4	..	
2481·6	4	2481·79	2	2931·7	2	2931·56	1
2536·9	4	2537·09	2	2949·5	4	2949·82	3
2677·7	2	2677·35	1	3080·7	8	3080·22*	4
2685·2	8	2685·24	3			3081·59	8
2729·1	6	2729·08	3	3118·6	8	3118·56*	5
2737·9	2	..		3171·4	6	3171·49*	5
2765·8	8	2765·88	3	3197·9	8	3198·25*	8
2834·3	4	2834·37	1	3326·0	4	..	
2837·3	4	..		3391·5	6	3391·73	4
2845·2	6	2845·23	2	3665·6	2	..	
2870·2	2	..					

It is important to notice the very close accordance in the values of the relative intensities in the two tables, which we think justifies the identification of the lines also in the few cases where the difference between the wave-lengths is slightly greater than is to be expected from the usual accuracy of Urbain's measurements of wave-lengths of rare earths. Only a few of these lines, denoted by an asterisk, were included in Urbain's original list of the lutetium lines.

In order to verify the origin of Eder's lines and to endeavour to find out why most of these lines were not included in Urbain's original list, we have examined the optical spectrum of a highly purified cassiopeium preparation kindly presented to this institute by Dr. Auer von Welsbach. At the same time Dr. Coster has photographed the X-ray spectrum of the same preparation and found it to contain no trace of an element with atomic number 72. Our exposures revealed in the spectral region investigated (2500-3500 Å) all the lines observed by Eder and brought certain new features to light, which made it possible to understand why these lines were not observed in the original investigation of the lutetium spectrum published by Urbain in 1907. In an exposure in which the salt was placed at the carbon anode of the arc, the celtium lines came out sharp and in about the same relative intensities as in Eder's investigations, but when the salt was placed at the cathode, most of the celtium lines were much more intense and very diffuse and broad, especially in the part of the arc nearest to the cathode. The only celtium lines which also under these conditions came out as sharp as the rest of Eder's cassiopeium lines were the four previously mentioned lines denoted in the table by an asterisk. On account of this behaviour of most of the celtium lines they will be very difficult to observe in less pure preparations. Some exposures taken with a less concentrated (10 per cent.) sample, formed by mixing Auer's preparation with a scandium salt, did in fact show only the usual lines, whereas most of the celtium lines could be detected only by the presence of an increase of the continuous background of the plate. Urbain's results are therefore easy to understand, if we assume that the preparations investigated by Urbain in 1907 contained a comparatively small amount of the element with atomic number 71, and that only after treating the preparations further a concentration was obtained sufficient for the production of the diffuse lines, which in 1911 were ascribed to the presence of a new rare earth element, which was called celtium.

As to the origin of the lines given by Urbain as celtium lines, and not present in Eder's cassiopeium spectrum, we have found in the spectrum of Auer's preparation a weak line with wave-length 2738·1 Å, which may be identified with a celtium line (2737·9 Å). The line 3326·0 occurs as a weak line in the mentioned mixture of scandium and cassiopeium, but could not be found in the spectrum of Auer's pure preparation. As Urbain states that scandium was present as an impurity in his preparations, and as the scandium spectrum is not very well known, we have also taken a strong exposure of this spectrum, but could not find any of the remaining lines. Probably these lines have the same origin as the other celtium lines, but as they are weaker they will need a very strong exposure, especially if they also are diffuse. For such strong exposures we had not sufficient material.

It is of interest to add that in a recent note (*Comptes rendus*, t. 176, 1923, p. 496), which first came to our notice after the above was written, dealing with the discovery by Coster and Hevesy of the element hafnium with atomic number 72, Urbain himself directs attention to the particular behaviour of the lines ascribed by him to celtium, and expresses the conjecture that these lines—the observation of which was the basis for his belief in the presence of a new element in his preparation—may actually constitute the spark spectrum of the element 71.

H. M. HANSEN.
S. WERNER.

Universitetets Institut for teoretisk Fysik,
Copenhagen, March 20.

On Celtium and Hafnium.

IN our letter of February 9, which appeared in NATURE of February 24, p. 252, we have shown that the element hafnium, of atomic number 72, detected by us in zirconium minerals, possesses physical and chemical properties quite different from those ascribed to a rare earth element celtium, the discovery of which was announced by Urbain in 1911, and which recently was believed by Dauvillier and Urbain also to possess the atomic number 72. In a communication of February 19 to the Paris Academy of Sciences (*Comptes rendus*, vol. 176, p. 496, 1923) Urbain discusses the same problem and still claims the identity of his celtium with our hafnium and by a claim of priority rejects the latter name. In the meantime, through the investigation of Hansen and Werner (see NATURE of March 10, p. 322, and the above letter in this issue) on the optical spectrum of hafnium and on the spectrum ascribed by Urbain to celtium, new data have been brought to light, and we should therefore be glad to take the opportunity to complete our arguments as regards the questions discussed by Urbain.

To put the matter clearly we must go back to the time preceding the announcement of the discovery of celtium. As is well known, Marignac succeeded in 1878 in isolating from a mineral from Ytterby a substance which was considered to be a new element and called ytterbium. In 1905 Auer von Welsbach (*Wiener Anzeiger*, x., 1905; see also *Sitzungsberichte* 115, July 1906, and *Lieb. Ann.* 351, p. 464, 1907) announced the discovery that this substance was a mixture of two elements, for which he later proposed the names aldebaranium and cassiopeium. Detailed information with regard to the spectra of these elements and their atomic weights was first published by him in 1907 (*Wiener Sitzungsberichte*, 116, December 1907), shortly after a similar announcement had been made by Urbain (*Comptes rendus*, 145, p. 759, 1907), who was the first to publish lists of lines for the separate spectra of the two new elements, and proposed the names neo-ytterbium and lutetium. By continued purification of his preparations, Urbain observed in the following years a gradual change in the spectrum and magnetic properties and announced in 1911 (*Comptes rendus*, 152, p. 141) the detection of a further element, which was called celtium, for which a separate list of spectral lines was published.

Through the work of Hansen and Werner referred to above, it is clear, however, that the latter lines are due not to a new element but to the element which was called lutetium by Urbain and cassiopeium by Auer von Welsbach, in the spectrum of preparations of which the same lines were also observed by Eder in 1915. To this we may add that the same view is supported in a striking way by investigations on the magnetic properties of the various preparations. The circumstance that the paramagnetism of Urbain's preparations of 1911 was three or four times smaller than that of his former preparations need not be explained as due to the presence of a new element, but may be considered as a consequence of the gradual concentration of the element cassiopeium or lutetium in his preparations. Thus Stephan Meyer (*Wiener Sitzungsberichte*, 117, p. 955, 1908) in his investigations of the magnetic properties of the rare earths had already found in 1908 for the paramagnetism of a cassiopeium preparation a value almost as small as that measured in 1911 by Urbain for the preparation which was believed to contain the largest percentage of celtium.

In view of the conclusion drawn by Hansen and Werner as regards the optical spectrum, this circumstance may be taken as a proof that the original preparations of Urbain from 1907 (*Comptes rendus*, 145, p. 759) contained only a rather small fraction of the element cassiopeium or lutetium and presumably much less than the preparations of Auer von Welsbach of the same time. In this connexion it is of interest to mention that, according to the quantum theory of atomic structure, the element of atomic number 71 must be assumed to be diamagnetic in its trivalent chemical compounds. In fact the absence of paramagnetism of such compounds is a necessary consequence of the theoretical conclusion that in the triply charged ions of the element 71 we first meet with a completed electronic configuration of four quantum orbits. (See N. Bohr, "Theory of Spectra and Atomic Constitution," pp. 106, 114, Cambridge University Press, 1922.) It was this conclusion which led to the anticipation verified by our discovery of hafnium, that the element 72 should not have properties analogous to the rare earths, but be a homologue of zirconium.

As will appear from the above, the existence of an element with the properties ascribed to celtium cannot be maintained, and we think ourselves justified in concluding that the important problem of the nature of the element 72 may be considered as settled by the discovery of hafnium and the investigation of its properties. While thus the general conclusions of Dauvillier and Urbain must be rejected, there remains the question, of secondary importance, whether the two extremely faint X-ray lines observed by Dauvillier in Urbain's preparation, which was believed to contain celtium, can have been due to a contamination of this preparation by a trace of hafnium. In the discussion of this point it must be emphasised, in the first place, that Urbain, in the course of his purification, made all possible precautions to remove elements other than the rare earths from his preparations. In fact, in his note in *Comptes rendus*, 1911, quoted above, M. Urbain states that "des impuretés de toutes sortes, provenant soit des vases, soit des réactifs, s'accumulèrent nécessairement dans des eaux mères successives. J'ai fait différents traitements de ces eaux mères par l'hydrogéne sulfuré, l'ammoniaque et l'acide oxalique, de manière à éliminer tout ce qui dans cette substance n'appartenait pas au groupe des terres rares. J'ai examiné ensuite la terre purifiée et parfaitement blanche." Now our investigations of the chemical properties of hafnium have shown that this element, just like zirconium, can be separated easily from the rare earth elements by a treatment with oxalic acid.

Only two lines of the element 72 were claimed to have been detected by Dauvillier, and even in the case of the most intense of these lines we meet with the difficulty that it falls in the same place in the spectrum as the strongest zirconium line in the second order. As an argument against ascribing this line to zirconium, Urbain states that the optical spectrum of his preparations did not show any zirconium line. An investigation of Urbain's spectrum of the "celtium" preparation, however, does not show any line of the hafnium spectrum (see Hansen and Werner, NATURE, March 10, 1923) either. If the possibility of the presence of one of these elements in Urbain's preparation can be taken seriously into consideration, it should be expected that zirconium would be present in greater amount. In fact, zirconium was likely to be more abundant in the original mineral than hafnium, and a purification of rare earth preparations from zirconium and not simultaneously from hafnium, by treating with oxalic acid or any other method mentioned by Urbain, is scarcely imaginable in view of the close similarity of the chemical properties of

these elements. As mentioned in our previous letters, however, the two lines ascribed by Dauvillier to the element 72 were lying 4 X-units distant from our Hf-lines, which is distinctly more than the limit of experimental error,[1] whereas the lines of the elements 70 and 71 measured by Dauvillier (*Comptes rendus*, vol. 174, p. 1347, 1922) on the same plates closely agree with the measurements of the same elements obtained by Coster (*Phil. Mag.*, vol. 44, p. 546, 1922). As the two lines according to Dauvillier were extremely faint, they may easily be explained to be of some other origin.

It is of interest to note that, at various times, announcements have been made as to the complexity of zirconium. In 1845 Svanberg claimed that in decomposing zircons he discovered a new element "norium," with a lower atomic weight than zirconium. His and Sjögren's (1853) statements were later disproved by the work of several investigators including Marignac. In 1864 Nylander reported the existence of two earths in zirconia. Five years later, by a spectroscopic investigation of zirconium, Sorby was led to announce the discovery of "jargonium" and Church of "nigrium." Finally, in 1901 Hofmann and Prandtl thought that they had found in euxenite a new element related to zirconium. It is also interesting to note that Mendeleéff, as we learn from Sir T. E. Thorpe's letter in NATURE of February 24, p. 252 (March 17), suggested that the extraordinarily discordant values for the atomic weight of titanium, found by several chemists, might be due to the presence of a homologous element of higher atomic weight in their material. Whether these statements in some cases may be explained by the presence of hafnium in the minerals and preparations under investigation, it is not easy to decide. The intricate chemistry of zirconium, and the great chemical similarity of hafnium with this element, would in fact have made any establishment of hafnium very difficult before the development of the powerful method of X-ray analysis.

Constitution of Black Maketu Sand.

THE letter of Messrs. Smithells and Goucher in NATURE of March 24, p. 397, under the above title calls for a short reply from me.

The authors do not state with what object their experiments were made, but the results of these differ so much from my own as to suggest that the sand examined by them was from another part of the deposit at Maketu, or possibly from an entirely different source, such as that on the Taranaki Coast.

Is "Prof. Bohr's conclusion that no new element is present" to be found in any paper published by him? If not, it would be interesting to know upon what authority the authors quote it.

As my original communication on this subject was made to the Chemical Society, I feel it my duty to send to the Society, in the first place, the results of my own further experiments and also those of the examination of my preparations by Drs. Coster and Hevesy. This I hope to be able to do in time for publication in the Society's Journal for April.

ALEXANDER SCOTT.
34 Upper Hamilton Terrace, London, N.W.8,
March 26.

[1] Dauvillier's measurements carried out since the announcement of our discovery, on other material which possibly contained hafnium, have already led him to give new values for the same wave-lengths, which are respectively 3·4 and 2·3 X-units larger (NATURE, February 17, 1923)

Tracks of α-Particles in Helium.

IN a recent issue of NATURE (January 27, p. 114), Messrs. Ryan and Harkins have published some photographs of the ionisation tracks of recoiling atoms produced by collision of α-particles with air molecules. We have been also engaged in photographing the tracks of α-particles from polonium in helium, and have obtained some interesting photographs. Besides the long range recoil helium atoms, we have obtained a few photographs in which are shown the ionisation tracks of all the constituent parts of a helium atom, namely, of the nucleus and the two bound electrons. They are shown in Fig. 1 (i and ii).

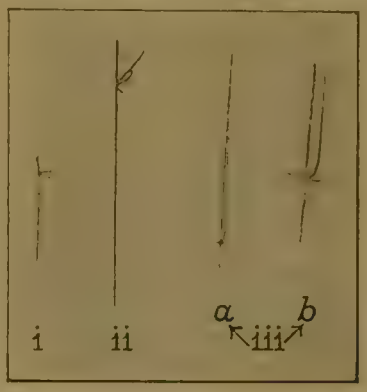

FIG 1.

It will be noticed that both the electrons are ejected on the same side of the α-particle track. One of us (D. Bose, *Zeit. f. Phys.*, 12, 207, 1922) has previously photographed the ionisation tracks of several thousands of α-particles in hydrogen, and in no case was a photograph obtained which showed simultaneously the ionisation tracks of the two constituents of a hydrogen atom. This behaviour can well be explained on the model of the normal helium atom proposed by Lande and others, according to which the two electrons move in orbits which are inclined to one another. If an α-particle strikes the atom at the moment when both the electrons are near the point where their orbits cross, then the probability of their both being ejected in the same direction is very great.

The photograph (Fig. 1, iii, *a*) presents some special points of interest. In it is shown (1) the track of the α-particle before and after collision, (2) that of a recoiling nucleus, (3) four small tracks which radiate out from the circular patch and are due to the electrons which are ejected from the atom under collision. The circular patch, which is absent in the photographs of other recoiling atoms, resolves when seen under high magnification into a number of lines radiating from a centre. An enlarged photograph which has been slightly retouched is reproduced in (iii, *b*). It will be noticed also that the path of the recoil atom is very much curved in the beginning—a phenomenon we have not observed before in the many tracks of the recoil atoms which we have obtained in air, hydrogen, and helium. Its length is 4 cm., and is larger than any of the other recoiling atom tracks which we have obtained in helium.

Judging from the number of the electrons which have been emitted we have here evidently the collision of an α-particle with an atom more complex than either hydrogen or helium; we can suppose it to be either nitrogen or oxygen; such atoms can well be expected to be present as impurities. But it is difficult

to conceive how a recoiling atom of mass 14 or 16 can produce an ionisation track of 4 cm. length in a mixture of helium and water vapour, after suffering a collision with an α-particle from polonium. The distance at which the collision took place was about 3 cm. from the source. Probably the phenomena observed can best be explained on the assumption that here we have the case of the breaking up of a nitrogen nucleus by an α-particle with the expulsion of a hydrogen nucleus, which produces the long ionisation path. The cause of the large initial curvature of the path remains to be explained. It is not due to the superposition of a number of large-angled single scatterings.

Further experiments are in progress.

Porto Santo in Pleistocene Times.

THE Geological Society of America has recently published an extremely interesting review and summary of the recent work and opinions of specialists on the Pleistocene, by Dr. H. F. Osborn and Dr. C. A. Reeds. The chronology and changes of level are fully discussed, and we are invited to consider the evidence in favour of changes in sea-level depending upon the amount of water withdrawn as ice. It is improbable that the views of Depéret, in particular, will be accepted as they stand; but it must be admitted that the glacial periods produced some world-wide changes of level, and the question how great these were becomes an extremely interesting one.

The statement of these views is an invitation to geologists all over the world to search their coasts anew, and try to detect evidence of the postulated phenomena. In the course of this search I believe few places will better repay study than Porto Santo, in the Madeira group. I have on more than one occasion directed attention to the small I. de Cima, separated from the main island by a narrow and shallow channel (Boqueirao de Cima), yet possessing a very distinct species of snail in great abundance, found nowhere else. The postulated fall of the sea in glacial times would, I think, certainly unite Cima with the main island, yet the snail has not passed. That the snail has evolved in post-glacial times seems improbable. Between Cima and the main island are some rocks, and on one of these (Sircada) Miss Nancy Paterson collected for me some fossil snails, *Ochthephila obtecta* and others. I thought at first that we had evidence of a submerged island or neck of land between Porto Santo and Cima, once supporting a snail-fauna, but now washed by the waves. Further investigation, however, convinced me that the Sircada Rock was nothing more than a large piece of the adjacent high cliff of the main island, which had fallen into the sea, carrying the fossils with it. Objection may be made that in postulating long constancy of level for the islets Cima and Baixo I do not take into account denudation, which would have worn them down had they not risen (or the sea fallen). These islets are essentially flat on the top, and wear away extremely slowly above, but rapidly along the sides, so that we have what may be called *lateral denudation*. This can be seen going on at the present time.

Continuing the investigation, we naturally ask for marine pleistocene beds. These are to be found at the Campo do Baixo, west of the Villa Baleira on the main island. A wide well has been dug at this place, and it is possible to go down and explore it fully. At a depth of about 30 feet is a layer of marine pleistocene rock, full of shells firmly cemented together. This rests on dense, dark, volcanic rock, but there is no evidence of volcanic activity in the material above. Far above the marine bed, near the surface, is dense sandy rock containing snail shells, *Plebecula bowditchiana* (Fér.), *Ochthephila tectiformis* (Sby.), etc. *P. bowditchiana* is an extinct species, but it is not certain that it lived so much later than the marine beds, for it might have been carried in shifting sand, though it is a heavy shell to travel in that manner. Another species of snail, *Ochthephila coronata* (Desh.), was found in the marine layer itself. A fine slab of the marine deposit, carrying many shells, has been presented to the British Museum. I broke up a quantity of the material, and submitted a series of the shells to Mr. J. R. le B. Tomlin, who has very kindly determined them as follows: *Erato prayensis* Rochebrune, *Mitra fusca* Swainson, *Cerithium vulgatum* Brug., *Bittium latreillei* Payr. (abundant), *Alectrion incrassata* Müll., *Trivia pulex* Sol., *Rissoa costulata* Ald., *Alvania testæ* Ar. and Magg., *A. punctura* Mont.(?), *Mangilia striolata* Sc., *Natica* sp. (? *macilenta* Phil., or perhaps *sanctæ-helenæ* Smith), *Anadema cælatum* A. Ad. (?), *Calliostoma exasperatum* Penn., *Cardium papillosum* Poli, *C. tuberculatum* L., *Ervilia castanea* Mont., *Macrocallista chione* L. To these I may add the common *Columbella rustica* L., which was not submitted to Mr. Tomlin. A peculiar Naticoid and some others were not determined.

This is a modern fauna, many of the species still abundant in the sea near by. The place is not far from the sea, a short distance behind the line of sand hills, which are planted with tamarisk. The level of the deposit is little if at all below that of the shore, and we are not obliged to postulate anything more than a deeper bay, now largely filled up with sand.

This brief discussion merely opens up the subject, and it is to be hoped that some student will pursue the matter further, combining a charming holiday with profitable research. T. D. A. COCKERELL.

The Hermit-Crab and the Anemone.

IN NATURE of December 2 and 30, 1922, vol. 110 (pp. 735 and 877), there are two very interesting letters from Dr. J. H. Orton on the relationship between these animals and the advantages of the partnership. Many years ago (September 1901) I took the opportunity, after a short visit to Millport, to watch the habits of the species *Eupagurus prideauxii* and *Adamsia palliata*, which seem always to live together, the association presumably being needful for their mutual welfare. Possibly my observations of these may be helpful in understanding the ways of other Paguridæ.

On the occasion referred to, I brought with me to Sheffield a specimen of the hermit-crab and Adamsia living together. To ensure their being undisturbed during my experiments, they were settled by themselves in a small aquarium and regularly fed with oysters and cockles. I thus managed to keep them alive and healthy for nearly six weeks. The Adamsia, as is usual, had attached itself head downwards on the underside of the shell occupied by the hermit-crab, and the two sides of its base had grown upwards and round the shell, so as to meet in the centre above the back of the crab, forming a tube or sack for its accommodation, the crab having far outgrown the small Natica-shell, which, later, was found at the bottom of the sack.

Matters had thus been arranged between the two animals so that, as is well known, the head of Adamsia hung downwards and its tentacles, brushlike, were carried over the surface of the sand when the hermit-crab travelled from place to place. The first two pairs of the long, slender walking legs of the hermit-crab were directed backwards in a manner which suggested protection of the anemone, but this appearance was misleading, as it was soon found that their function, in addition to that of locomotion, was to steal the food collected by the anemone. This was effected most cleverly by an underneath upwards sweep of the leg, the terminal portion of which passed through the tentacles of the anemone and carried any food found therein swiftly to the mouth of the hermit-crab. It is interesting to note that these limbs seem specially adapted to this purpose. The part mentioned (the dactyl) in this species (*E. prideauxii*) is long and very slender, and its inner or concave side is beset with a row of many long fine hairs projecting inwards like the bristles of a brush, thus forming a very effective instrument for sweeping out the mouth of the Adamsia. At times, also, the claws were doubled under the hermit-crab's body and seized the food which had been secured by the anemone. At first food was supplied for the joint use of the animals. Later on I experimented and tried to *feed* the *anemone alone*, but in this I never succeeded, as although the hermit-crab could not see the food, it was so instantly detected and swiftly swept away, as described, that one wondered how the anemone ever got sufficient for its own needs. Whether some sensory hairs on the dactylopodite had anything to do with detection I cannot say.

My observations seem to show that, though both animals benefit, the advantages of the partnership in this particular case are very largely on the side of the hermit-crab, which, in addition to being supplied with food, may possibly derive some benefit from the Adamsia's power when irritated, of firing a broadside of stinging threads through the numerous portholes in its sides. So far as I can see at present, the only profit to the Adamsia is that of being carried from place to place, and thus afforded a better chance of securing food, for which, as has often been pointed out, the downward direction of the mouth and tentacles is most favourable. The anemone may, of course, derive other advantages which are less obvious, and the parallel case (to which Dr. Orton has directed attention) of the little tropical crab, *Melia tessellata*, which carries in each claw a living sea anemone and uses it as a weapon and also (like Adamsia) as a collector of food, suggests the possibility.

On the face of it, Adamsia and the little anemones first mentioned seem to be the willing slaves of the hermit-crabs, for P. H. Gosse's observation, in 1859, of how *E. prideauxii* with its claws transferred the Adamsia from its old shell to a new one ("A Year at the Shore," pp. 241-247), which was later confirmed by Col. Stuart Wortley (*Ann. and Mag. Nat. Hist.*, 1863, p. 388), seems to show that the hermit-crab is the keenly interested active agent in arranging matters so advantageously for itself. With the common hermit-crab (*E. bernhardus*) and *Sagartia parasitica*, however, matters are reversed. Here the anemone evidently takes the initiative, and except perhaps by the camouflage, etc., which is afforded by its riding on the whelk-shell occupied by the hermit-crab, the latter appears to derive no benefit. The position assumed by the anemone is unfavourable to the hermit-crab's sharing in its captures; moreover, the walking legs of the hermit-crab are not adapted to securing a portion, the concave side of the dactyl of *E. bernhardus* being smooth and practically free from hairs, whilst the limb is otherwise unsuitable for the purpose. It seems as though *S. parasitica* has taken a hint from Adamsia and improved upon it.

Paradoxical Rainfall Data.

Prof. McAdie, in Nature of March 17, p. 362, directs attention to the apparently paradoxical fact that the wettest month observed in 37 years at Blue Hill observatory fell in June, the month with the lowest rainfall average, whereas the driest month fell in March, the month with the highest average. The coincidence is a curious one, but less improbable than might at first sight appear, since the monthly rainfall is at many stations extremely variable. Some idea of its extreme variability may be gathered from the following table, showing the distribution in half-inch intervals of the rainfall at Rothamsted for 70 years from March 1853 to February 1923.

	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.
0		4	1	5	1	3	5		1		1	2	23
·5	9	11	11	8	7	9	5	4	5	4	4	6	83
1·0	12½	19	13	12	18	10	11	13	13	7	11	9	148½
1·5	7½	10	16	14	12	13	7	7	11	14	4	14	129½
2·0	10	8	10	10	12	6½	11	8	17	5	18	7	122½
2·5	9	4	7	12	8	10½	5	13	7	11	11	6	103½
3·0	7	5	4	3	5	5	9	9	6	6	6	10	75
3·5	9	6	4	3	1	5	2	7	2	5	4	3	51
4·0	4	1	3	1	3	2	5	3	3	4	7	6	42
4·5	2	2	1	2	2½	3	5	2	1	3	3	1	27½
5·0					½		2		2	3	1	1	9½
5·5						1	2	1	1	4		2	11
6·0						2				1		2	5
6·5							1	3		2			6
7·0										1			1
7·5													
8·0									1			1	2
8·5	70	70	70	70	70	70	70	70	70	70	70	70	840

The seasonal effect appears to be more strongly marked at Rothamsted, where the mean rainfall (per day) in October is about 54 per cent. greater than that in April, than it is at Blue Hill, where the mean rainfall (per day) in February is only about 24 per cent. more than in June. Nevertheless, even in the Rothamsted data, the variability of rainfall in the same calendar month is so great that the mean values give little or no indication as to which month should be expected to score a record for rain or drought. Indeed, both records are at present held by December, which in 1864 gave one-sixteenth of an inch of rain (0·063), and in 1914 gave 8·103 inches.

Rothamsted Experimental Station,
Harpenden, Herts.

Rothamsted and Agricultural Science.[1]

By Sir JOHN RUSSELL, F.R.S.

THE Rothamsted Experimental Station has just passed its eightieth year, having been founded in 1843. Its study has always been the growth of crops, with periodical excursions into problems of utilisation; the method of experiment has always been essentially statistical in that the field experiments were repeated year after year without modification, with the result that a unique mass of data has now accumulated which is proving of the greatest value for statistical investigation.

The work at Rothamsted falls into two great periods: the first, when Lawes and Gilbert were actively exploring the possibilities opened up by the knowledge of plant nutrition gained by the early nineteenth-century workers; and the more recent period, when close study of the soil has revealed certain factors of high scientific interest, and, one is constrained to believe, ultimately of great practical importance.

The great problem which Lawes and Gilbert set out to solve was to account for the fertilising value of farmyard manure. The fact was well known, but there was no satisfactory explanation. Lawes and Gilbert proceeded by a method that still—after eighty years—remains our best. It was known that farmyard manure contained three groups of components: organic matter; nitrogen compounds; and ash constituents—potassium, calcium and magnesium salts, phosphates, silicates, etc. They therefore arranged vegetation tests with these various groups. The old idea was that the fertilising value lay in the organic matter, but Liebig, in 1840, had argued brilliantly against this view, and suggested instead that the ash constituents, especially the potassium, calcium and magnesium salts, were the effective agents. Lawes and Gilbert were prepared to recognise the necessity for these mineral salts, but insisted that the nitrogen compounds were equally required. To put the matter to a test, they laid out four plots of ground, receiving respectively no manure, farmyard manure, ashes of an equal amount of farmyard manure, and these ashes plus a nitrogen compound (ammonium sulphate). The results were as follows:

PRODUCE OF WHEAT PER ACRE, BROADBALK FIELD, ROTHAMSTED, 1844.

	Grain. (bush.)	Straw. (cwts.)
No manure	16	1120
Farmyard manure (14 tons per acre)	22	1476
Ashes of 14 tons of farmyard manure . . .	16	1104
Ash constituents + nitrogen compounds and ammonium sulphate, up to . . .	26¼	1772

They concluded that farmyard manure owes its value, not to the organic matter as was for long supposed, nor to the ash constituents as Liebig had suggested, but to the ash constituents plus nitrogen compounds.

Now this discovery was of the greatest importance in plant physiology, but Lawes and Gilbert did not follow it up in that direction. Instead they applied it at once to an important agricultural problem then ripe for solution. There was then (as nearly always now) a shortage of farmyard manure on farms, and agriculturists had for generations sought for substitutes, but with little success. Lawes and Gilbert saw that the mixture of ash constituents and nitrogen compounds would form an effective substitute, and further, that it could be obtained in very large quantities, and of course independently of farmyard manure. Geologists had discovered vast deposits of calcium phosphate, which chemists had shown how to render soluble. Engineers were developing the manufacture of coal gas and producing large quantities of ammonium sulphate, while potassium compounds could be obtained without difficulty from wood ashes. Lawes and Gilbert therefore proceeded to make mixtures of these substances which they advised farmers to use.

Few experiments have proved so fruitful in stimulating scientific inquiry—it is still opening up new fields at Rothamsted—and in ministering to human needs, as this simple field trial carried out eighty years ago on the Broadbalk field at Rothamsted. At first farmers looked with some misgiving upon this new kind of manure (which was called "artificial manure" to distinguish it from farmyard manure, then known as "natural manure"); it seemed incredible that a harmless-looking powder without smell or taste could act as potently as the old-time richly odorous farmyard manure. But they soon came to recognise its value, and before long they were using many thousands of tons a year. It is safe to say that the remarkable development of British agriculture which took place between 1843, when Rothamsted began, and 1870, would have been impossible without artificial fertilisers. During that period British farmers kept pace with the growing needs of the population; indeed they did more, for they helped to change the "hungry 'forties" into the more plentiful 'seventies. The use of artificial fertilisers is now developed throughout the civilised world and the industry has attained enormous dimensions.

This was the greatest achievement of Lawes and Gilbert. They did many other things for the farmers of their day, but this alone leaves us owing them a great debt of gratitude.

As the use of artificial fertilisers spread there arose, as one might expect, many problems of great scientific interest or technical importance. Thus it soon appeared that weather conditions profoundly affected the response of crops to artificial fertilisers. The same fertiliser mixture which in one season gave results fully equal to, or even surpassing those of farmyard manure, would, on the same farm and even in the same field, prove a failure in another season. This is well shown in the fluctuations in yield on the Broadbalk wheat field at Rothamsted.

The effect of soil is also sharply marked. On our heavy soil at Rothamsted the best results are usually obtained by a fairly liberal use of phosphates, but there is less necessity for large dressings of potash. But on the much lighter soil of Woburn potash is considerably more important, while phosphates

[1] Discourse delivered at the Royal Institution on Friday, February 9.

are less needed, and, indeed, beyond a certain quantity appear to do actual harm. It is obvious, therefore, that a complete manure drawn up on the basis of the Rothamsted experiments would fail in practice to give the best results on a lighter soil. As an instance the following may be quoted, this being one of a general scheme of experiments organised from Rothamsted:

BARLEY: LIGHT SANDY SOIL IN SUFFOLK, 1922.

	Bush. per acre.
Complete artificial manure . .	21·5
Incomplete manure: phosphate omitted	27·5
No manure	16·0

In this instance the omission of phosphates has raised the yield by 6 bushels per acre. As against this, an array of instances might be brought from clay farms where a phosphate is the one and only thing that causes crop increases. Any one who had to deal with

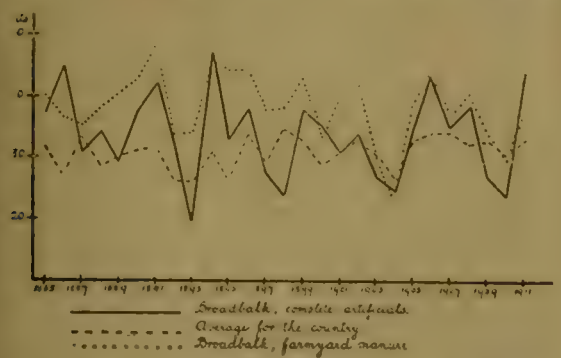

FIG. 1.—Yields of wheat from Broadbalk plots manured with complete artificial manures, and farmyard manure, respectively, compared with the average yield for the whole country.

farmers' problems could multiply apparent contradictions and inconsistencies of this kind. When one collects, as we have done at Rothamsted, the results of field trials with artificial manures made in different parts of the country they seem at first to be simply a tangled mass of unrelated facts.

Now it is the business of the man of science to sort out a tangle of this kind, to reduce it to order, to find the general principles running through it, and finally to prove the correctness of his conclusions by being able to predict with certainty what will happen in given conditions. The recognised method of procedure is to discover the various factors at work and investigate them one at a time. This is being done at Rothamsted in two ways: by field observations, and by quantitative laboratory measurements. Observations in the field show that each of the fertilising substances—phosphates, potassium compounds, nitrogen compounds, etc.—in addition to its general effect in increasing plant growth, produces certain specific effects which may be of advantage, or may be a disadvantage to the plant in the particular conditions in which it happens to be growing. Thus, phosphates have a special influence in hastening the ripening processes, which no doubt accounts for the Suffolk results just quoted. In the dry conditions of a sandy soil, ripening is already too early, and any reduction in an already short growing season cuts down the yield; in cold, wet districts, however, this property is very valuable.

In the early stages of the plant's life phosphates stimulate root development to a marked degree; this is well shown in their effect on swedes. Nitrogen compounds tend to increase leaf development and give greater vigour of growth, but beyond a certain point the advantage is counteracted by a loss of resisting power, and the plants may fall victims to attacks of disease. Crops—especially cereals—may be unable to stand up against the weather and may become "lodged." Indeed, the proper adjustment of plant nutrients affords plant pathologists one method of dealing with plant diseases.

Qualitative observations of this kind, while of high value, are not entirely sufficient: it is necessary to have quantitative measurements of as high an order of accuracy as possible. At Rothamsted this is done by means of water cultures and pot experiments; all the factors are controlled as closely as possible and the results are plotted on curves which can be studied in detail. This method was developed extensively by Hellriegel and is now in common use in agricultural laboratories.

The method naturally invites mathematical treatment, and attempts have been made, notably by Mitscherlich, to express the curve by equations. There is a seductive look about a mathematical formula which rarely fails to appeal to the biologist, but as a rule the number of experimental points obtained is much too small to justify mathematical treatment, and it is not surprising that investigators fail to agree. Ten years ago the fashion was for logarithmic curves; now it is for sigmoid curves, which are probably nearer the truth, though not yet a complete expression.

This method of studying single factors is pushed to a high degree of refinement in plant physiology laboratories, such as that of the Imperial College under Prof. Blackman, or that under his brother at Cambridge, and there can be little doubt that the effect of individual factors on the plant will ultimately be well known. All this work is giving valuable information as to causes and principles.

These curves show the relationship between yield and plant food supply at one particular temperature which remains constant, and one particular water supply which also remains constant. But a completely different set of figures would be obtained if the temperature were different or if the water supply were altered. Supposing one wished to take account of the effect of water supply as well as food, one would draw a series of curves, which would properly be expressed as a surface, and this has been done by one of the Rothamsted workers—Mr. J. A. Prescott—to show the effect of nitrate supply and spacing on the yield of maize in Egypt. The experiments had the advantage that the climatic conditions are less fickle there than here. It would be of the greatest interest to obtain such surfaces for other pairs of factors.

If an attempt were made to study factors three at a time, it would be necessary to prepare a series of surfaces and to embody them in a figure in four dimensions, which is certainly beyond the capacity of the ordinary agricultural investigator. But in agricultural field work the factors do not vary one at the time, or

even two or three at the time; there may be half-a-dozen variables. This, of course, enormously complicates any attempt to apply to field conditions the results obtained by these single factor physiological experiments. It is possible that when the physiologists have completely elucidated all the single factors, some one will be able to synthesise the material and build it into some great conception or expression that will contain all, and thus account for the field results. But history shows that the genius capable of effecting a synthesis of this sort is very rare and might have to be awaited long.

We have therefore adopted another method at Rothamsted, which is being worked alongside of the single factor method. Statisticians have, during recent years, been evolving methods for dealing with cases where several factors vary simultaneously. These methods have been applied by Mr. R. A. Fisher to the Rothamsted field data, and he has been able to trace

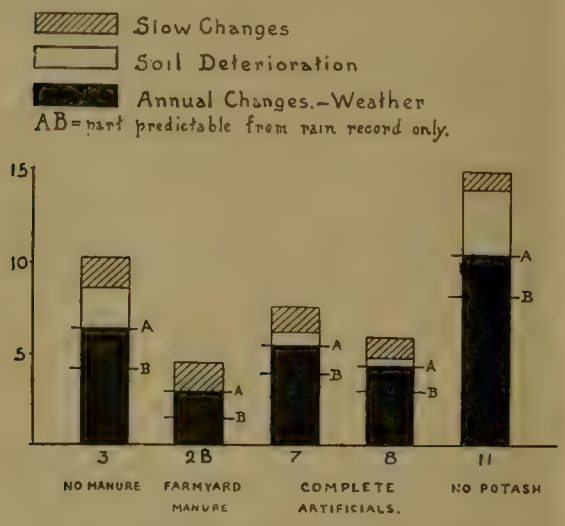

FIG. 2.—Mr. R. A. Fisher's results showing amounts of predictable variation in wheat yields, Broadbalk, Rothamsted.

certain statistical regularities which foreshadow the possibility of important developments.

Thus, the yields on the Broadbalk wheat field vary every year, apparently in a most erratic manner. But analysis of the figures showed that the factors causing variation could be disentangled and expressed quantitatively; there are slow changes in the field, such as changes in the amount of weeds, etc.; deterioration of soil; and weather changes such as rainfall, temperature, etc. (Fig. 2).

As might be expected, the effects differ according to manurial conditions; *e.g.* the influence of weather varies with the manure. Important differences appear between farmyard manure and artificials. The variation in yield is less where farmyard manure is given than where artificials are used. Further, the so-called complete manure appears not really complete at all; there is soil deterioration going on; but with farmyard manure no such deterioration is produced. The different kinds and quantities of artificial manures produce different effects on the variation in yield, the magnitude of which has been worked out.

Having disentangled the factors Mr. Fisher has proceeded to analyse the effect of rainfall, and he finds that part of the weather effect is predictable when rainfall is known. Rain above the average in autumn is somewhat beneficial; in winter and in summer it is harmful, and in spring it is less frequently harmful. As before, the effects are much more pronounced with complete artificials than with farmyard manure. The actual facts have long been known in a general way, but here is an exact quantitative measurement.

The great advantage of this statistical regularity is that it indicates the possibility of expressing in terms of chance the influence of the weather, soil, etc., on crop yields. We hope ultimately to be able to say to the farmer, given such and such conditions of soil and weather, the chances are so many to one that such and such an increase of yield will be obtained by the use of a specified fertiliser. The expression would be understood by every farmer, and he would readily decide whether to take the risk or not.

Much greater results would also follow. At present the farmer cannot cover his risks of low yields by insurance, the companies not yet having sufficient data. We hope and believe that these statistical investigations will afford the basis on which such data will be obtained. At present the position approximates to that of life insurance in the eighteenth century, when the statistical regularity of mortality was first established, after which the first life tables could be constructed. There still remains a mass of detail to work out, but the fundamental problems are now being attacked, and we see no reason to regard them as insoluble. If the expectancy of crop yields proves to be calculable the farmer will be able to insure himself against crop failure, and so meet one of the worst vicissitudes of his troubled life by merely taking out an insurance policy—perhaps even by subscribing to a particular newspaper.

We are constrained to admit that the work is still far from completion, and in the meantime agriculture has fallen on difficult days and farmers are turning to us to ask how they can obtain large crops in the most economical way. It is not general principles they want, but particular instructions.

We are not in a position to give an absolute clear-cut prescription to any farmer, but we are going a long way to meet him. Some of our field experiments of special interest or importance are being repeated at other centres where soil and climatic conditions are all different. The results are compared with ours, or with others that have been obtained, to ascertain how far or in what direction any of our conclusions would need modification in a particular district.

We now return to an important result to which I have already referred. Over a period of years the artificial manures have not proved quite as effective as farmyard manure; there has been more variation in yield and they have not so well maintained the fertility of the soil as farmyard manure has done. On some crops the effect is marked; clover responds better to farmyard manure than to artificials. It appears then that Lawes' and Gilbert's views that the fertiliser value of farmyard manure lay in its ash constituents plus nitrogen compounds is only a first approximation, and that farmyard manure does

something or contains something which artificial manures do not. This difference we are now engaged in exploring.

The same method of procedure is used as in studying the effects of artificial fertilisers. A full scientific investigation into the causes is carried out, but simultaneously an attempt is made to find some working solution of the farmers' problems. The shortage of farmyard manure is still as acute as ever, and to keep more animals with the view of making more is uneconomic. At Rothamsted we have attempted to produce farmyard manure from straw artificially and without animals. This has been done by Mr. E. H. Richards and Dr. Hutchison by simulating the essentials of the natural process, namely, watering straw with a salt of ammonia (actually ammonium sulphate, but calcium carbonate is mixed with the straw), and leaving the heap so that the air can get in and the organisms can do their work. The product is not yet equal to the natural substance, but it is steadily being improved, and the very serious difficulties are gradually disappearing in Mr. Richards's competent hands. Five years ago a few ounces only of this artificial farmyard manure had been prepared; last year several thousand tons were made on various farms in different parts of the country, and the news is spreading. The serious problem of developing the work from the laboratory to the farm scale has been possible through the generous and public-spirited action of Lord Elveden. There seems here the possibility of aid to the farmer and of the development of an important new industry.

Meanwhile a full scientific investigation is being carried on to discover wherein farmyard manure differs from artificials. One important difference is already known and is being investigated by Dr. Keen. Farmyard manure opens out the soil particles leaving bigger pore spaces; it allows of the retention of more moisture and the better circulation of air. All these effects are beneficial.

There is also another difference. Farmyard manure and also plant residues (which are substantially the same thing) decompose in the soil, giving rise to many substances of different types. The plant foods are among the end products: indeed, in natural conditions, and, to a large extent, in farms and gardens also, it is in this way that plants obtain their food. In using artificial manures we supply these end products at once instead of waiting for them to be liberated gradually by the natural decomposition. Further, we do not by any means know the whole of the processes whereby plant food is made. But there are certain intermediate products, and it is quite possible that some of these may have a special effect on the growing plant. Curious stimulating effects are produced by substances formed when soil is steamed, or when oxidation is accelerated by addition of charcoal, and we have obtained the same results with small quantities of picric acid; such bodies might well be formed as intermediates in the decomposition of farmyard manure. The whole effect suggests an action like that of the vitamins of plant physiologists or the auximones of the late Prof. Bottomley. The chemical department at Rothamsted, under Mr. Page, is following out the process, and the botanical department, under Dr. Winifred Brenchley, will test any intermediate products which may be obtained.

A further important factor, which probably governs the whole situation, is that a great part of the process of decomposition and plant food production appears to be brought about by living organisms in the soil. Simultaneously, therefore, with the chemical and botanical investigations, the various biological departments are busily engaged in studying the organisms that are doing the work.

It is a wonderful story that is being revealed. The soil is shown to be the abode of a vast population of living organisms of the most varied kind. Some of them are remarkably small; among them one which brings about the last stage in the formation of nitrates—an organism which Rothamsted just missed forty years ago: another, also just missed at Rothamsted, which has the remarkable property of fixing nitrogen in the nodule of the clover plant. Others are larger and more easily picked out, but their exact place in the soil economy is not easy to determine: probably they are concerned in the preliminary stages of the decomposition.

It is impossible to peer into the soil with a microscope, so that indirect methods of exploration have to be used. At Rothamsted the organisms are counted and the work they do is estimated by some chemical process: virtually we take a census of population and production in the soil. Like other census methods, it is comparative only: a single census is not much use; it is not until several have been taken that one can find how the numbers and activities of the population are being affected by various conditions. The census is therefore repeated periodically and the results plotted on curves from which it is possible to deduce the effect of various factors on the particular organisms counted.

These curves brought out the remarkable result that partial sterilisation increased bacterial activity, and investigation showed that the normal virgin soil must contain other organisms besides bacteria—organisms, moreover, which were detrimental to bacteria and tended to keep their numbers down. A search for such organisms showed that protozoa were present: many forms have since been found in the soil, some of which are known to feed on bacteria. Mr. Cutler has discovered how to count them, and with the co-operation of willing workers has succeeded in carrying out perhaps the most remarkable census yet made of the bacterial and protozoan population of a natural field soil. Before the census began many months were spent in perfecting the methods and technique, and in making preliminary studies of the soil. The details were carefully arranged with the statistical department, and it was decided to take the census many times at short intervals. Time to a bacillus or a protozoan is a different thing from what it is to us, and instead of taking the census every ten years, or even every ten days, it was taken daily, and at the same hour every day. Many repetitions were needed so that the statistician might feel safe in drawing conclusions from the data. The census was therefore made every day for 365 consecutive days, and no less than seventeen different organisms were enumerated.

A team of five workers kept the investigation going

without intermission—Sundays, Bank Holidays, and Christmas Day—for a whole year. A mass of data was obtained of high statistical value which is proving of the greatest importance in the study of the soil population. One of the most interesting results was the proof that the soil population is not steady in number as had always been assumed, but is in a violent state of flux. Every organism observed—protozoon or bacterium—showed great daily variations, which seemed to be independent of external conditions. At least one showed a two-day periodicity. The fluctuations of the amœbæ were of special interest as they were exactly the reverse of the bacterial fluctuations. Close examination of the curves leaves no doubt that the fluctuations of the amœbæ cause the fluctuations of the bacteria, high numbers of amœbæ causing low numbers of bacteria, and low numbers of amœbæ allowing bacterial numbers to rise: but why the amœbæ fluctuate remains a mystery.

In the case of bacteria it has been possible to make even closer observations. A census organised by Messrs. Thornton and Page has been taken each two hours for several days and nights; but again the same wonderful fluctuations are seen. As might be expected, the amount of work, as measured by the nitrate present, alters from hour to hour. But the curve was not quite what was expected: the increases in amount of nitrate could be understood as representing the work done by bacteria, but the decreases were more difficult to explain. There was no rain to wash it out and there were no plants to take it up; yet the nitrate tends to disappear. The results suggest that some organism is absorbing it. Algæ and fungi could both do this, and both are found in the soil: Dr. Muriel Bristol and Dr. Brierley are closely studying them.

Perhaps even more remarkable than the daily changes are the great seasonal changes. It appears that the whole soil population is depressed in winter and in summer, and is uplifted in spring and autumn. How this comes about we do not know. The phenomenon does not seem to be confined to the soil; the algæ in a pond and the plankton in the sea, like the organisms in the soil, all seem to feel the joy of spring; it is as if Virgil had got hold of some great truth in natural science, which we have not yet been able to express in cold scientific terms, when he says that in spring "Aether, the Almighty Father of Nature, descends upon the earth, and blending his mighty frame with hers, gives life to all the embryos within." ("Georgics," Bk. II. 11, 324-327).

The number of organisms in one single gram of soil—no more than a teaspoonful—often well exceeds 40 millions. This looks big, but it is difficult to form an idea of its immensity. If each unit in the whole array could be magnified up to the size of a man and the whole caused to march past in single file, they would go in a steady stream, every hour of the day and night for a year, a month and a day, before they had all passed. We must think then of the apparently lifeless soil which we tread beneath our feet as really throbbing with life, changing daily and hourly in obedience to some great laws which we have not yet discovered; pulsating with birth, death, decay, and new birth. And if the wonder were not sufficient, we know that in some way these lowly organisms are preparing the food for our crops—the crops on which we ourselves feed. It is possible—it is even probable—that our attempts to learn something of this wonderful population may lead to some degree of control which would have valuable economic results. But even if this never happened the work would still be justified because it shows to the countryman something of the abounding interest of his daily task and of the infinite wonder of the soil on which he spends his life.

The Present and Future of Marine Engineering.

THOUGH shipping and shipbuilding are passing through a period of severe depression it is generally considered that more prosperous times are in sight. The War, as is well known, occasioned tremendous losses to the shipping of the world—we ourselves lost over seven million tons—but this has been more than made up, and the latest edition of Lloyd's Register Book shows that there are afloat to-day, exclusive of sailing vessels and vessels under 100 tons, some 29,000 steam and motor ships of a total tonnage of 61,000,000 tons. This is an increase of some 14,000,000 tons on the figures for 1914, but while in that year the United Kingdom owned nearly 44½ per cent of the world's sea-going steam tonnage our present proportion is just over 33½ per cent. In spite of this, we are still the greatest users of ships and the greatest builders of ships, though to-day shipping returns are only too eloquent of ships laid up, berths empty, shops closed, and machinery idle.

While this is the case, the competition for such orders as are to be obtained has forced all designers to study more closely than ever the economics of shipbuilding and marine engineering, and a vast amount of investigation and research is being carried out. Especially noteworthy are the inquiries being made into the respective advantages of the steam engine, the steam turbine, and the oil engine. As a result of this, the shipowner is to-day offered a bewildering variety of machinery of various types, all of which have their respective merits. A quarter of a century ago marine machinery was more or less standardised. Practically every ship built then was fitted with cylindrical boilers burning coal, and triple expansion engines. Of the 61,000,000 tons of shipping referred to above, 51,000,000 tons are still driven by such engines. Remarkably successful as it has been, the reciprocating steam engine, however, has long been superseded in naval vessels and fast liners by the steam turbine, and now its very existence is threatened, on one hand by the turbine combined with mechanical, hydraulic, or electric transmission gear, and on the other hand by numerous forms of the Diesel internal combustion engine.

The present position of the marine steam turbine is scarcely less critical than that of the triple expansion engine. It is twenty-one years since the marine steam turbine was used commercially, and it is estimated that turbines of more than 50,000,000 horse-

power have been fitted in ships. There are many types, such as those of Parsons, Curtis, Rateau, De Laval, Zoelly, and others, but it was the Parsons turbine which led the way. Originally the turbine was connected directly to the propeller shaft. To be economical, however, the turbine should run fast and the propeller slow. To achieve this object, Sir Charles Parsons introduced helical tooth gearing, the turbine shaft having a small pinion which geared into a large wheel in the propeller shaft. Such single reduction gearing was successfully tried in the s.s. *Vespasian* in 1909. Since then double reduction gearing, consisting of a train of four wheels, has been largely used. In this arrangement the pinion in the turbine shaft drives a wheel on an intermediate shaft, and a pinion in the second shaft drives the wheel in the propeller shaft. By this means it is possible to run the turbine at three or four thousand revolutions per minute while maintaining a suitable propeller speed. One of the finest examples of such gearing is found in the latest liner of the Canadian Pacific Railway Company, the *Empress of Canada*. Completed last summer, this vessel is the largest passenger ship running in the Pacific. Of 21,520 tons, she is driven by twin sets of Brown Curtis turbines, each set having H.P., 1st I.P., 2nd I.P., and L.P. turbines, which drive the propeller through double reduction gearing. The main gear wheel on the propeller shaft alone weighs 65 tons, while one complete set of gearing weighs about 200 tons. Additional interest attaches to this installation, due to the application of the principle of the nodal drive devised by Dr. J. H. Smith, of Belfast, in order to avoid trouble due to torsional oscillations of the various shafts.

But while mechanical gearing of this kind has been used extensively, there have unfortunately been serious failures which have given rise to more than a little doubt as to the trustworthiness of such gearing. The elucidation of the causes of the failures is among the most pressing problems facing the marine engineer. References to this were made in the recent presidential addresses of Engr. Vice-Admiral Sir George Goodwin, Dr. W. H. Maw, and of Prof. T. B. Abell to the Institute of Marine Engineers, the Institution of Civil Engineers, and the Liverpool Engineering Society respectively, and the urgent need for further research was pointed out. Failures occur from the wearing or the breaking of the teeth. In some instances where wear has taken place the trouble has not been serious, and with further use the condition of the gearing has improved. When fracture takes place the broken pieces sometimes fall clear of the wheels, and the damage is slight. If, however, the broken teeth are caught in the wheels distortion and crushing takes place immediately, and the gear wheels are rendered useless. The causes of failure have been variously assigned to inaccurate cutting of the teeth, want of alignment of the shafts, improper design, unsuitable or faulty material, and the occurrence of excessive torsional vibrations in the shafting and gearing. This latter subject has been dealt with recently in a valuable paper by Messrs. A. T. Thorne and J. Calderwood, read before the North-East Coast Institution of Engineers and Shipbuilders.

Recent improvements in steamships, whether driven by turbines or reciprocating engines, have been largely concerned with the stokehold. Though cylindrical boilers still remain the rule, water-tube boilers are being fitted in increasing numbers, and in such vessels as fast torpedo craft and cross Channel steamers the combination of the water-tube boiler with the geared turbine is likely to hold its own for a long time. The water-tube boiler leads to a reduction in weight, it can be forced at a high rate of combustion, and it is admirably adapted for use with oil fuel. Naval vessels have used water-tube boilers exclusively for many years, but it is only recently the mercantile marine have taken kindly to them. The most notable example of the use of water-tube boilers in a merchant ship is found in the White Star liner, the *Majestic*, the ex-German ship *Bismarck*, which it is anticipated will run the *Mauretania* very close for the blue ribbon of the Atlantic. The world's greatest ship, the *Majestic*, is 912 feet long, and displaces, when fully loaded, 64,000 tons. The turbines, originally designed for 66,000 S.H.P., are supplied with steam from 48 water-tube boilers of the Yarrow-Normand type. These have a total heating surface of 220,000 sq. ft., or some 40,000 sq. ft. more than the boilers of H.M.S. *Hood*. Like most of the Atlantic liners the *Majestic* is now fitted for burning oil fuel. Some 15,000,000 tons of ships burn oil instead of coal to-day, and provided supplies of oil prove sufficient, the time is not far distant when the coal-burning ship will be obsolete. When used under boilers three-quarters of a pound of oil will do the work of a pound of coal. Then, too, the use of oil-fuel leads to a great reduction in the stokehold staff, and from the shipowners' point of view it has the advantage of making it possible to reduce the time of a ship in port. The *Olympic*, for example, can fill her oil-tanks in six hours; coaling used to take 4½ days.

It is not, however, with the reciprocating engine or with the steam turbine that the future of marine engineering appears mainly to lie, but with the Diesel internal combustion engine. Diesel brought out his engine so long ago as 1893. Its success ashore has been remarkable. For driving ships it has had to serve a long probation. The Atlantic was first crossed by a Diesel-driven ship in 1910. Since then its progress has been more rapid, and practically all marine engine builders have taken up the construction of Diesel engines of one form or another. The motor ship has undoubtedly come to stay, and the placing of an order by the Union Steamship Company of New Zealand with the Fairfield Company for a motor driven vessel of 20,000 tons with a speed of 18 knots marks an important epoch in its history. This notable vessel will be 600 ft. long, and will be driven by four sets of Sulzer two-cycle Diesel engines of an aggregate power of 13,000 I.H.P. This is twice the power of any motor vessel running at present. Such a step is evidence of the degree of trustworthiness and success achieved by the motor ship.

The credit of building the first motor passenger liner belongs to the Elder Dempster Line, which commissioned the *Aba* for its West African trade last year, and has now placed the *Adda* on the same run. Other companies are following the lead thus given, and while in 1914 there were only 297 motor ships afloat there are now 1620, with an aggregate tonnage of more than one

and a half million tons. Shipowners have the choice of a dozen types of Diesel engines, such as the Burmeister and Wain, the Werkspoor, the Sulzer, the Beardmore, the Cammellaird-Fullagar, and the Doxford, some being of the four-cycle and some of the two-cycle type. These engines differ in many respects, but all have the same characteristic in being more economical than the steam engine. Mention may also be made of the experiment being carried out with the Still engine, in which the top of the piston is acted upon by the pressure of the burning gases, while the underside is acted upon by the pressure of steam raised in a small boiler heated by the exhaust gases.

In addition to the advocates of the steam turbine and the Diesel engine there is yet another school of engineers which believes the future of marine propulsion lies with what is known as the electric drive. This system has been developed far more in America than on this side of the Atlantic, and all recent capital ships for the United States Navy have electric transmission. In these vessels oil-fired boilers supply steam to Curtis turbines driving electric generators which supply current to the motors on the propeller shafts. The general adoption of such a system, it was pointed out by Prof. Abell, may lead to remarkable alterations in the plans of ships, as the engine-rooms can be placed between decks or otherwise as thought most suitable. A turbine-electric plant involves the use of boilers, turbines, condensers, generators, and motors, but an alternative is to replace the boilers, turbines, and condensers by Diesel engines. The various proposals have been reviewed in his book on "Electric Ship Propulsion" by Commander S. M. Robinson, of the United States Navy. He there divides both naval and mercantile vessels into classes, and states which type of machinery he considers most suitable. For the cargo tramp he would have Diesel engine and electric drive, for other merchant vessels and for large war vessels steam turbines and electric drive, while for destroyers and light cruisers he would retain geared turbine.

From the foregoing it will be seen that the whole practice of marine engineering is, as it were, in the melting-pot, and what the standard form of marine propulsion will be in the future is difficult to see. Given trustworthiness, it is economy which has the deciding influence; economy in weight, economy in space, economy in upkeep, economy in fuel. What the continual striving after economy has done in the past can be judged by the fact that, fifty years ago, to convey a hundred tons of cargo a mile required 18 to 20 lbs. of coal; to-day the same result is obtained with 1½ to 2 lbs of oil. Finality was thought by some to have been reached when the compound engine was introduced. Great advances have been made since then. But while it may not be possible to effect revolutions on the scale of the past, the time is far distant when improvements will be impossible.

Obituary.

Sir James Dewar, F.R.S.

SIR JAMES DEWAR died at the Royal Institution, in his eighty-first year, on March 27. He had been working in his laboratory until late on the night of March 20 and was taken ill in the early hours of the following morning.

Our scientific edifice is thus suddenly deprived of one of its main pillars; we shall not easily appraise the loss. The immensity and sustained originality of his genius, the service he rendered to our civilisation, can be but insufficiently appreciated outside the small circle of intimates who witnessed his work and, having penetrated through the thick mask of modesty and reticence which he habitually wore, could disregard his sometimes brusque, inconsequent manner, his volcanic, torrential outbursts of picturesque criticism—knowing these to be but the expression of an extreme intensity of conviction and purpose and an overmastering honesty. At heart he was full of human sympathy, a most gentle and lovable nature—but the presbyter was ever in him.

As an experimentalist Dewar stood alone: there has never been a greater, probably none so great. Science loses in him a worker of peculiar breadth of originality, a most fascinating character; how much the world is poorer it little knows. He was of a type—almost primitive, in this competitive age, in honesty of purpose—now fast becoming extinct, a lineal descendant of his great countryman, Joseph Black, in no way less successful than his predecessors, Young, Davy and Faraday, in adding to the reputation these pioneers created for the Royal Institution as a centre of scientific discovery and invention. He also made it a social centre of great attraction and cast over it an æsthetic spell which it had not previously known. Davy sought society but did not fashion it. Dewar could rarely be persuaded into it but became himself noted as a host, on account of his own great conversational power and the beauty of the surroundings he accumulated: his home was the salon of science and art.

As a lad Dewar met with an accident which, in after life, he regarded as fortunate. Falling through the ice, he contracted rheumatic fever and was long unable to attend school but became intimate with the village joiner. In those days, Scotland having been in close commercial relation with Italy, fiddles abounded and the lad had musical tastes. With his own hands he made several violins, from one of which we heard the sweetest of music conjured forth, by a skilled lady performer, on the occasion of the celebration of his golden wedding, less than two years ago. He always regarded the training he thus received as the most important part of his education and the foundation of the great manual dexterity which he displayed in his work and his lectures. He often complained to me of the sad lack of such ability in the modern student. His master in chemistry was Lyon Playfair. Dewar was one of the few who could appreciate Playfair's great scientific ability and were able to gauge the loss of his early deflexion into the tortuous paths of politics, which Playfair himself regretted in later life. The two men became fast friends and Playfair was long chief admirer of his pupil's brilliant ability. At one time, I believe, Playfair endeavoured to secure his entry into the dyestuff industry; had Dewar's masterful energy been operative

in this field our position to-day might well have been one of unrivalled supremacy.

Dewar also came under Kekulé's influence at Ghent. Körner was then assistant in the laboratory and Dewar and he became associated in all sorts of devilry—Körner being a great practical joker and Dewar a wild young Scot. The stamp of the organic chemist was thus burnt into his soul at a critical period—the spell of Körner's marvellous preparative skill being cast over him; he often referred to the time. His mathematical and physical proclivities were thus broadened and he became a complete chemist in spirit. The Dewar benzene-formula, though an imperfect expression of modern knowledge—paper formulæ are but shorthand expressions of character—has not yet lost its vogue. His name is also written in the pyridine chapter. He and I were the first users of sulphuric chlorhydrol, SO_3HCl. He did notable work before he came south—first with Tait, in which he laid the foundation both for his later application of a vacuum in preventing heat exchanges and of charcoal as an absorbent; and with M'Kendrick, with whom he carried out an important inquiry on the physiological action of light.

In 1875 he was appointed Jacksonian professor of natural experimental philosophy in the University of Cambridge and became the colleague of Prof. Liveing. He never carried out the prime duty of his office—the discovery of a cure for the gout—though in early days he sought unsuccessfully for the qualification which might have helped in the work; unfortunately, he only spoilt his digestion and so, in later years, was perforce an extraordinarily careful liver.

Two years after his appointment at Cambridge he also became Fullerian professor of chemistry at the Royal Institution, London. He had twice lectured there previously on the work he had done with M'Kendrick. The second lecture (March 31, 1876), his trial trip, was probably the most carefully prepared, certainly the most logical, discourse he ever delivered; I well recollect how fascinated some of us were by it.

Even if it be possible for a man to serve two masters, the task becomes beyond human power when ghosts aid one of them. As an artist, Dewar had the innate belief of primitive man in ghosts and in the Royal Institution laboratory, miserable as was the accommodation it afforded, the ghosts of Davy and Faraday were ever about him. Let us hope that his successor will be gripped by thoughts of the trinity which Dewar's entry into their Valhalla has established. To have served the Institution honourably, in a way to justify mention in history on a par with them, is an achievement he, in his modesty, scarcely contemplated as possible and yet he ever aimed at it. The feeling that he had so much exceeded Faraday's period of office and not only maintained but also steadily improved the quality of his work, I have reason to think, was year by year a more and more powerful mainspring of action in the indomitable fight against circumstances which he waged during these late bitter times of strife. He was a terrible pessimist.

To return to Cambridge, he found there no tradition of practical achievement to influence him. His colleague Liveing and the Master of his College, Dr. Porter, were perhaps the only men who fathomed his outstanding ability. The crudity of youth was still upon him and the free manners of a Scottish University were not those of conventional Cambridge—his sometimes imprecatory style was not thought quite *comme il faut* by the good. No attempt was made to tame him or provide means for the development of his special gift of manipulative skill. Yet he soon began to exercise an influence which probably has had more to do with the marvellous recent advance of the Chemical School at Cambridge than is commonly supposed. The fine volume of collected researches in spectroscopy which Prof. Liveing and he published a few years ago, is a memorial not merely to their activity but of the example they set as exact observers in a field which, at that time, was in sore need of cautious workers. And the work he did in London had its reflex effect at Cambridge.

Dewar was not great as a teacher. His mind was of too original and impatient a type. He never suffered fools gladly and students are too apt to be foolish—at our old Universities, even to ape the part of superior beings. His forte lay in directing competent hands, not in forming them. He worked himself and through skilled assistants, not through pupils. He was violently impatient of failure in manipulation and his work was almost entirely manipulatory. He, therefore, never created a school. The pity of it is that circumstances were such that he never had a properly large staff. That he accomplished so much with the assistance of the few able men who have aided him is proof of his exceptional skill as a director. It is unfortunate that the Davy-Faraday laboratory was not, from the beginning, organised on lines which would have placed its resources in his hands rather than at the disposal of undirected individual workers; it is a grievous fact that he leaves no followers trained to use his incomparable methods.

Nominally a chemist, Dewar's work lay in fields of his own creation, not borderlands but regions before uncultivated. He was no mere experimentalist but an artist to his finger-tips and in nose, tongue, eye and ear—a perfect judge of *Wein*, *Weib* and *Gesang*, giving to these terms their widest significance; music came next to science in his affections.

Though deeply read and a great lover of poetry and literature, he lacked the gift of ready literary expression—except in his letters and conversation—and was often an incoherent lecturer, yet his lectures were the most masterly and fascinating displays ever witnessed. He set a standard which has made the Royal Institution table remarkable throughout the world. Faraday was celebrated for the simplicity of his style—Dewar is to be thought of on account of the daring of his displays, the wonderful refinement and appositeness of his demonstrations, all most carefully arranged and rehearsed in advance. He was a great scientific actor, playing plays with the most thrilling of plots and entirely original special scenery for each performance. His manner, his brogue, even his impatience, gave a peculiar charm to the impression he produced; but you did well to have been behind the scenes if you wished to gather the full meaning of his message. His demonstrations were unique in character; few realise the infinite loving care he devoted to their preparation. In their simplicity they were often profound. I can never

forget the impression I received when I first saw him burn diamond under liquid air—the gradual accretion of the carbon dioxide snow-shower and the blueing of the fluid by ozone, also demonstrated by the iodine test. Then the rapid uprush of the mercury in a barometer-tube full of air when the tube was cooled with liquid hydrogen: it all but knocked the top off. Or again, the production of ozone at the surface of solid oxygen by the impact of ultra-violet radiations. At such moments—and there were many such—the heart beat with joy at the significance of his feats of inspiration.

To the outside world Dewar is known as the man who liquefied oxygen and other gases and as the inventor of the vacuum flask—his name will probably go down the years on this last account. It is due to his memory that this should be spoken of henceforward as *the Dewar flask*: it was his free gift to the public; had he protected and developed the invention he might have amassed a fortune and fully endowed his chair.

The real value of his work on gases, apart from the impetus it gave to the industrial use of liquefied air in particular, is to be found in the many new directions in which he developed the art of inquiry at low temperatures. Perhaps the most illuminating is the inquiry into the heat capacities of the elements at the temperature of boiling liquid hydrogen: the discovery of a periodic variation, corresponding with that in atomic volume at ordinary temperatures, is not only surprising but may well prove to be of profound significance in the future interpretation of atomic properties in terms of electronic structure.

Like his great predecessor, Dewar leaves a mass of material to be interpreted by his successors. Unfortunately, he was all too careless in placing his work on record. Like Turner, he painted for his own pleasure, to give expression to his genius—but too often did not put the picture aside for a Ruskin to glory over.

In two essays printed in the Proceedings of the Royal Institution—one on the "Charcoal Vacuum Septennate" (1909), the other on the "High Vacuum Septennate" (1917)—I have briefly summarised his later and chief work at low temperatures; in the latter I also briefly review his work generally as Fullerian professor up to 1917. These essays may serve to guide students. With him, however, we lose a vast unrecorded experience.

Of late years he had returned to a first love—the soap film: it saved his life and was his solace, keeping him from utter despair during the War. He only left it to go to his last bed of sickness. It is to be feared the record of the work is a very imperfect one. Those who were at his last lecture on "Soap Films as Detectors," on the opening of the Friday evenings this year, will not forget the occasion. He was obviously in physical distress and feeble but mentally as alert as ever; the artist was never more to the fore. His appeal was that made in Cory's beautiful *Incantation*.

My sun is stooping westward. Entrancèd Dreamer haste,
There's fruitage in my garden that I would have thee taste.

But he was the "entrancèd Dreamer"—the fruitage he gave us to taste was lovely; nothing so exquisite had before been brought in such perfect form under the public eye. He recalled Young to us; then, playing with a delicate pencil of air upon his liquid lute, he made visible, in hues of the rainbow, the multitude of its melodies, during over a third of his hour. He had never before lingered so long over a single demonstration. He knew that we were gazing upon no mere play of colour but upon a dance of the molecules such as is at the root of life—and death!

How many of us were serious listeners to the message he felt was to be his last, that he was most bent on making, to his urgent appeal on behalf of the Institution which he had served so long, so well, so nobly—was to serve even up to the moment of his death? He will have worked to no purpose if his appeal be unregarded. The fate and future of science in our country is at stake: nothing less. The Egyptians, thousands of years ago, could make worthy provision for the soul of a boy king of eighteen who had done nothing. Surely our civilisation cannot be so backward, so thoughtless, so unmindful of its present peril, that it will not properly maintain an altar and a virile priesthood to keep alive the memory of men like Davy, Faraday and Dewar in the one way they would all wish—by extending their works in the service of mankind, to its salvation.

H. E. A.

PROF. A. S. BUTLER.

ARTHUR STANLEY BUTLER, emeritus professor of natural philosophy in the University of St. Andrews, died at his residence at Upper Redpits, Marlow, Bucks, on March 3. He was a worthy scion of a family distinguished in the church, in education, in letters, and in athletics. His grandfather, the Rev. Dr. George Butler, senior wrangler, was the distinguished headmaster of Harrow; one uncle was Dr. Henry Montague Butler, master of Trinity College, Cambridge, whose charm of manner he possessed; another uncle was the well-known Arthur G. Butler, Dean of Oriel, a not undistinguished athlete. His father, the Rev. George Butler, D.D., at one time vice-principal of Cheltenham College, was latterly Canon of Winchester; his mother, Mrs. Josephine Butler, an author, philanthropist, and active pioneer in higher education of women.

Prof. Butler was born on May 17, 1854; educated at Cheltenham and at Exeter College, Oxford (of which his father—a Hertford scholar in his day—had been fellow), where he obtained first class in Moderations (mathematics) and first-class honours in the Final School. After further study at Oxford, at Cambridge in the mechanical workshop under Prof. James Stuart, and at Liverpool, he was appointed to the chair at St. Andrews in 1880.

Prof. Butler's experience, especially at Cambridge, made him realise how desirable it is that students of natural philosophy should carry out some experimental work in addition to attending lectures and class demonstrations. But like his predecessor, Prof. Swan, he had the difficulties of want of accommodation and suitable apparatus. In the first year at St. Andrews a special grant provided him with some necessary apparatus, and in a few years he succeeded in obtaining a good practical laboratory well furnished: and then all his students were required to do some practical work.

As a lecturer Prof. Butler was highly successful. His lectures to the ordinary class were characterised

by definiteness, with clear, simple, and eminently helpful expositions from fundamental principles; they were illustrated by most successful class experiments and demonstrations highly appreciated and much enjoyed, and were occasionally illuminated by quiet flashes of kindly wit: these were especially effective on the rare occasions when any student tried to make a disturbance. But probably he was at his best in his honours class, where his theoretical treatment was often very elegant and his demonstrations much to be admired.

Prof. Butler was well read, particularly in geography—he was a medallist of the Royal Geographical Society—Napoleon's Wars, and the Peninsular Campaigns. For many years he did much work as an examiner in Mathematics, Pure and Applied, and in English for the Civil Service Commissioners.

Sir William Thorburn, K.B.E., C.B., C.M.G.

The death of Sir William Thorburn, on March 18, at sixty-one years of age, is a loss which will be severely felt in the obscure fields of neurology and surgery which his scientific mind and clinical acumen did so much to illuminate.

William Thorburn was the eldest son of the late Dr. John Thorburn, professor of obstetrics in the Victoria University of Manchester, and obstetric physician to the Manchester Royal Infirmary. He entered the Owens College (afterwards the Victoria University) in 1876 and had a distinguished academic career. He obtained the B.Sc. London in 1880, the M.B. and B.S. in 1884, taking gold medals in medicine, obstetrics, and surgery, with a scholarship in medicine. He proceeded to the M.D. in 1885 and the F.R.C.S. in 1886. On the death of his father in 1885 he took up surgery and held junior posts until he was elected on the honorary staff of the Royal Infirmary in 1890, becoming full surgeon in 1901 and consulting surgeon in 1920.

With a particularly acute and logical mind influenced by the teachings of the late Prof. James Ross, Sir William Thorburn was early attracted to the problems presented by injuries of the nervous system, and his first contribution to medical literature was a paper on "Obstetrical Paralysis," published in the *Medical Chronicle* in 1886; this was followed by a paper on "Injuries of the Spinal Cord" published in 1887 in *Brain*. In the field of research thus early indicated he was a pioneer, and his work resulted in various publications which have made him for many years past a recognised authority all over the world on the surgery of the spinal cord.

In 1891 Sir William Thorburn obtained the Jacksonian prize of the Royal College of Surgeons and was later Hunterian professor; he was also president of the Neurological Section of the Royal Society of Medicine.

Sir William Thorburn was always interested in medical education; a first-rate teacher himself, he trained many who are now teachers in our medical schools, and was successively surgical tutor, lecturer on surgical pathology, professor and emeritus professor of clinical surgery in the University of Manchester. His wise advice and willing help were of great value to the University, not only in the organisation of surgical teaching but also in its general policy and administration. As an examiner he had great experience, particularly at the Royal College of Surgeons, where he was chairman of the Court of Examiners and at the Universities. During the War he was at first, as lieutenant-colonel, in charge of the surgical division of the Second Western General Hospital, afterwards serving with great distinction as consulting surgeon in France and the Mediterranean. He was knighted in 1919.

Of distinguished personality and strong character, with decided opinions, and a fluent and witty speaker, Sir William Thorburn will long be remembered with affection by all who came under his influence.

Current Topics and Events.

As already announced (p. 439), the Government, at the last moment, in deference to the general protest, dropped its proposal to make a charge for admission to the British Museum. It was agreed in the House of Commons on March 26 to delete the clause in the Fees (Increase) Bill which gave power to the trustees of the museum to make regulations imposing charges for admission. The old Act of Parliament remains in force, under which the British Museum is, in the words of Sir Hans Sloane, "preserved and maintained, not only for the inspection and entertainment of the learned and the curious, but for the general use and benefit of the public to all posterity." The public, which has saved its rights, should be grateful to the trustees that they did not adopt the easier course of accepting the Government proposals. Had they done so they would no doubt have placated a Treasury rightly eager to cut down the estimates. They preferred, as trustees for the nation, to take higher ground. As a consequence it seems probable that they will have to renew the fight for an adequate appropriation, if not on this budget, at all events next year. Let the public, and especially the scientific public, be quite clear on this matter. Nobody will wish to gain his freedom of admission at the cost of hampering the curatorial and scientific work of the museum. But that this would be seriously hampered by any further reduction, there is no doubt. When such items as printing, binding, glass-ware, and cases for storage and exhibition are about doubled in cost, even an amount equal to the pre-war grants is hopelessly inadequate. No cutting down can be tolerated. Let the trustees continue to maintain a firm front in the highest interests of the nation, and they will be assured of national support.

According to an evidently inspired article in the *Children's Newspaper* for March 17, Dr. Alfred Daniell, of Edinburgh, author of a well-known "Text-book of the Principles of Physics," has elaborately reconsidered the whole theory of the Michelson-Morley experiment to his satisfaction, and has come to a

revolutionary conclusion. Dr. Daniell does not care to debate whether the shift of interference bands expected by Michelson is likely to occur, or whether the smaller value elaborately worked out towards the end of his life by Prof. Righi of Bologna is more likely to be correct. For according to him it is not the shift of bands that is important, but the fact that such bands appear at all. He has convinced himself that in the Michelson experiment no interference bands ought to appear unless there is an enormous relative motion between earth and ether. Hence, from the fact that interference bands do appear in every repetition of the experiment, Dr. Daniell concludes that such relative motion, amounting to 12,000 miles a second, is proved to exist. As the interference part of the Michelson-Morley experiment is of a straightforward and elementary character, it is difficult to understand how Dr. Daniell can have persuaded himself, and can seek to persuade others, that a motion of the ether is necessary in order to account for the appearance of interference bands when a beam of light is split into two halves and afterwards reunited. The premises upon which this deduction is based are not clearly stated in the article, though several equations are given from which it is apparently deduced, but they must include an error which Dr. Daniell has overlooked.

SIR ARTHUR KEITH, in the first of his Hunterian Lectures on "Man's Posture: its Evolution and Disorders," which appears in the *British Medical Journal* of March 17, reviewed the results of recent investigations which throw fresh light on how, when, and where man came by his erect attitude. He pointed out that extinct forms of man indicate that the upright carriage of the head was evolved later than the human form of the lower limb, of which the origin must be sought in Miocene or possibly Eocene times. He distinguished three phases of evolution. In the hylobatic phase the gibbon was differentiated from its cousins, the Old World and New World monkeys, by postural adaptations of bones and muscles in virtue of which it was orthograde and human in type as opposed to the pronograde monkeys. This differentiation probably took place towards the end of the Eocene period. The troglodytic phase was represented by the great anthropoid apes, evolved from the small anthropoids probably in pre-Miocene times. In the plantigrade phase, structural changes were confined almost entirely to the lower limbs. Seeing that man shares so many characters in common with the great anthropoid apes, Sir Arthur Keith held that man must be regarded as one of several aberrant branches of one great stem which began to break up into the various fossil and living forms at the beginning of the Miocene or the end of the Oligocene period.

VISITORS to Kew during the next few weeks should make a point of seeing a special exhibit of sports requisites arranged in Museum IV., the Museum devoted to British forestry. In this exhibit are to be seen cricket bats, tennis and badminton rackets, croquet mallets and balls, hockey sticks, and other articles in various stages of manufacture. Special interest is attached to the cricket bat, for, among the many thousands of woods known to science (upwards of 5000 kinds are represented in the Kew collections), no wood has been found that makes a suitable substitute for the best English willow (*Salix cærulea*) for the blades of bats. The material for the handles cannot be grown in the British Isles; that is the product of one or more tropical palms, *Calamus* spp. (Sarawak Cane). The heads of hockey sticks, the frames of tennis and badminton rackets, cricket stumps, and the handles of croquet and polo mallets are made of the best British ash, while croquet balls are often made of beech, and polo balls of willow. Various other articles are shown, but those mentioned suffice to indicate how dependent the sport-loving public is upon the home-grown timber industry.

THE Director of the U.S. Coast Geodetic Survey announces that Congress, at its recent session, made an appropriation of two thousand dollars to the State department for the support of the International Latitude Observatory at Ukiah, California, during the fiscal year 1924, or until some other provision is made for that station. In the estimates for the Coast and Geodetic Survey for the fiscal year 1924 there was included an item which, if it had been approved by Congress, would have authorised that bureau to carry on the variation of latitude observations at Ukiah as a part of its regular geodetic work. It is hoped that this authority will be granted during the next session of Congress in order that there may be no possibility of a break in the observations for variation of latitude which have been made continuously at Ukiah for the last twenty-three years.

WHILE the specification and measurement of artificial light has been brought to a very fair state of precision, there has, until recently, been little corresponding advance in dealing with natural illumination. The chief work in this field has been in connexion with the design of windows for schools, and an exhaustive report on this subject was issued by a committee of the Illuminating Engineering Society shortly before the war. A very complete survey of natural lighting, accompanied by an account of some highly interesting methods of measurement, was presented by Messrs. P. J. and J. M. Waldram at the meeting of the Illuminating Engineering Society on March 27. These methods are based on the relation between the value of unrestricted outdoor daylight illumination, and the illumination at a specified point in a room, a factor which should be substantially independent of climatic conditions and should serve as an indication of the access of daylight. Of special interest was the account of methods of estimating the effect of obstructions to light and the predetermination of daylight-access in buildings. These have recently proved extremely valuable in ancient light cases. Mr. J. W. T. Walsh gave some account of the work on parallel lines being done at the National Physical Laboratory, and paid a high tribute to the experimental skill revealed in the paper.

IT is stated in *Science* of March 16 that Mr. A. H. Fleming, of Pasadena, for many years president of the board of trustees of the California Institute of Technology, and its chief financial supporter, has recently given the Institute about 840,000*l.* as a permanent endowment fund. This gift, with Mr. Fleming's previous donations, make a total of more than a million sterling, which he has handed over to the Institute. In making this benefaction, Mr. Fleming recommends that the Institute should "specialise in research in chemistry and physics, under the direction of the most competent men obtainable, with the most liberal provision, in the way of salaries and equipment, for the prosecution of such work." He suggests that efforts should be made to seek out and assist "the superior student," and expresses his conviction that "the institute should always remain a privately endowed institution."

THE Paris correspondent of the *Times* announces that at a conference presided over by M. Le Trocquer, Minister of Public Works, on March 31, it was decided to recommend that Strasbourg time as well as summer time should be abandoned, but that during the summer trains should run half an hour earlier. It is hoped that work in Government offices will begin half an hour earlier from April 28 to November 3, and that business and manufacturing firms will adopt the same course. The Brussels correspondent of the *Times* reports that the Royal order fixing the establishment of summer time in Belgium for midnight on March 31 has been revoked, pending an agreement with neighbouring countries.

THE lectures at the Royal Institution after Easter begin on Tuesday, April 10, when Sir Arthur Keith will deliver the first of a course of four lectures on the machinery of human evolution. On following Tuesday afternoons there will be two lectures by Prof. A. C. Seward on the ice and flowers of Greenland and the arctic vegetation of past ages; and three by Prof. Flinders Petrie on discoveries in Egypt. On Thursday afternoons, commencing April 12, Prof. A. O. Rankine will give two lectures on the transmission of speech by light; there will be three lectures by Prof. J. T. MacGregor-Morris on modern electric lamps, two by Prof. E. G. Coker on engineering problems solved by photo-elastic methods, and one by Sir William Bayliss on the nature of enzyme action. Two Saturday afternoon lectures will be given by Dr. Leonard L. B. Williams, on the physical and physiological foundations of character, and two by Dr. Arthur Hill on the vegetation of the Andes and the New Zealand flora. The Friday evening meetings will be resumed on April 13, when the discourse will be delivered by Prof. W. H. Eccles, on studies from a wireless laboratory. Succeeding discourses will probably be given by Major W. J. S. Lockyer, Prof. C. V. Boys, Prof. F. Soddy, Prof. W. A. Bone, Mr. W. M. Mordey, and Prof. H. A. Lorentz.

THE council of the Geological Society has awarded the proceeds of the Daniel Pidgeon Fund for the present year to Mr. Howel Williams, of the University of Liverpool, who proposes to investigate the stratigraphy and vulcanicity of Snowdon.

IN view of the need for retrenching expenditure, the Government of India has decided to discontinue the publication of the Journal and Bulletins of Indian Industries and Labour after the issue of Vol. III. Part 1 of the Journal and of the Bulletins which are now in the press.

THE Secretary for Mines has appointed a subcommittee of the Explosives in Mines Research Committee to carry out investigations on the means employed for firing explosives. The members are: Sir Frederick L. Nathan, Mr. J. D. Morgan, Mr. W. Rintoul, and Prof. R. V. Wheeler.

THE following sympathetic message has been sent by the King and Queen to Lady Dewar through Lord Stamfordham: "The King and Queen have heard with much regret of the death of Sir James Dewar and desire me to express their true sympathy with you in your loss—a loss which will be shared by the whole world of science."

THE PRINCE OF WALES has, according to the *British Medical Journal*, signified his intention of being present at a dinner to be held on May 15, to celebrate the one hundred and fiftieth anniversary of the Medical Society of London. Lord Dawson of Penn, president of the Society, will preside, and a gathering widely representative of the medical profession is expected. The Medical Society of London, which was founded by Lettsom in 1773, is the oldest medical society in England; the Royal Medical Society, Edinburgh, is somewhat older, being founded in 1737.

AT the annual general meeting of the Ray Society on March 16, the following officers were re-elected:—*President*, Prof. W. C. McIntosh; *Treasurer*, Sir Sidney F. Harmer; *Secretary*, Dr. W. T. Calman. Mr. Joseph Wilson was elected a vice-president, and Mr. C. H. Beston and Mr. H. Taverner were elected new members of council. In the report of the council it was announced that the final part of Prof. McIntosh's "British Marine Annelids" would be published at an early date, forming the issue to subscribers for the year 1921. On behalf of the Society, congratulations were offered to the president on the completion of this monograph, of which the first part was published just half a century ago. The fifth and final volume of the "British Desmidiaceæ," prepared by Dr. Nellie Carter, is now ready for press, and will be issued to subscribers for the year 1922.

The issues of the *New Leader* from February 9 to March 9 contain a series of articles on "The Structure of the Atom," by the Hon. Bertrand Russell. These articles provide an interesting popularisation of modern work in atomic physics. Thus the idea that the universe seems like a clock running down, with no mechanism for winding up again, is compared with the experience of a tribe of insects which live for only a single spring day, and may therefore think it strange that there should be ice in the world, since they would find it always melting and never being formed. The

electron moving from one stationary state to another is compared to a flea, which crawls for a time and then hops; or to a man who, when he is insulted, listens quietly for a time, and then suddenly hits out. It is perhaps difficult for a technical reader to assess correctly the value of a popular article, but in this case a high standard appears to have been reached.

THE National Research Council of Japan has commenced the issue of journals dealing with astronomy and geophysics, chemistry, physics, geology and geography, botany, zoology, medical sciences and engineering, at intervals determined by the amount of matter available. The first six of the ten parts of the *Japanese Journal of Physics* for the year 1922 have been issued and cover 48 pages of original contributions, including one on the band spectrum of mercury by Prof. Nagaoka, and 26 pages of abstracts of 71 papers published by Japanese workers, and supplied by the authors themselves. The whole of the Journal is in English, and this fact will lead to a better knowledge and appreciation of the large amount of research work which is now being done in Japan.

THE Australian National Research Council has issued a report of its annual meeting held in Sydney in August last. The council was formed for national and international purposes in January 1921 by the Australian Association for the Advancement of Science, to which body it has to submit a full report of its work and proceedings on the occasion of each meeting of the Association. At the meeting Sir David Orme Masson was elected president of the council in succession to Sir Edgeworth David. Resolutions were passed urging the need for the State endowment of systematic research in the Pacific islands under Australian control, for research work in Australia in respect of refrigeration, and for laboratories to carry out industrial investigation and research. Offers of co-operation with the Commonwealth Institute of Science and Industry in measures for furthering these objects were made, and preliminary steps taken for the inauguration of a publicity campaign for the purpose of securing that the functions, operations, and financial needs of the Institute may be more fully appreciated by the Commonwealth Government, the Legislature, and the public generally. The council has decided to ask the Australian Association to regard it as a fully constituted body free to conduct its own affairs subject to instructions from the International Research Council. The first issue of *Australian Science Abstracts*, published by the Australian Research Council as a quarterly journal of abstracts of papers by Australian scientific workers, appeared on August 1, 1922. An invitation has been issued by the Commonwealth Government through the Research Council to the representatives of the Pan-Pacific Scientific Congress to hold the Congress in Australia in 1923.

THE Third Report of the Council of the National Institute of Agricultural Botany reveals satisfactory progress in the establishment of the work of the Institute upon a firm basis. The appeal for fellows has met with a gratifying response, and special interest attaches to the fact that the Prince of Wales and the Duke of York have consented to become honorary fellows. In the Crop Improvement Branch the conditions have now been settled on which yield trials of cereals will be carried out, and four new barleys were included in the "full trials" in 1922 at four different stations. The final year's trials will be carried out in the same districts in the spring of 1923. Varieties of oats, wheat, grasses, and clovers are all under observation, and the Institute is collaborating with the Plant Testing and Registration Station of the Board of Agriculture for Scotland, in the collection of strains of certain grasses and clovers, with the view of collecting information as a basis for a future scheme of trials and registration. Special research has been carried out by the official Seed Testing Station as to the value of "hard seeds" in clovers, and of the "broken growth" which occurs in germination tests. Increases have been made in the fees charged for seed testing in order to reduce the net cost of operating the station. At the Potato Testing Station, Ormskirk, various trials of immunity, maturity, and yield have been steadily carried on, more than 2000 entries being received for the official immunity tests. Progress has been made in the work of the Potato Synonym Committee, and less synonymous varieties are now being entered for the immunity trials.

THE second Sorby Lecture, delivered in the autumn of 1921 by Prof. C. H. Desch, has recently been published and is entitled "The Services of Henry Clifton Sorby to Metallurgy." As Prof. Desch remarks, Sorby was one of those amateur lovers of science who have played such a remarkable part in the scientific history of this country. Some have been members of noble families, such as Robert Boyle in the seventeenth and Henry Cavendish in the eighteenth centuries. Others have been men of the merchant or professional classes, possessing sufficient means to allow them to follow the bent of their minds. Such were Justice Grove, William Spottiswoode, Edward Schunck, and, greatest of all, Charles Darwin. To this group belonged Sorby. Free from the cares of a profession, he gave himself wholly to science, in the effort to advance which he worked with extraordinary diligence throughout a long life. Sorby was a pioneer in many branches of science, but left it to others to develop his new experimental methods and to fill in the details of his discoveries. His great manipulative skill and patience led him to found at least two new departments of experimental science — microscopical petrography and metallography. Prof. Desch has attempted to discover in the wide range of Sorby's scientific work, some connecting thread among the great diversity of his investigations, and he finds that a prominent motive in his work is the desire to understand the "form" of natural objects, using this word in its widest sense. The address deals, in the main, with that branch of Sorby's work which led to the foundation of metallography as a science. It is based on a careful study of his note-books and specimens, and

may be commended to all those interested in this matter, as an impartial and penetrating survey of the subject.

We have received from the Eastman Kodak Company their latest catalogue, No. 9, dated January 1923, of organic chemicals. There are 1500 chemicals listed, with prices, most being products of the Eastman Kodak laboratories.

The latest catalogue (No. 8, 1923) of second-hand books issued by Mr. W. H. Robinson, 4 Nelson Street, Newcastle-on-Tyne, although dealing mainly with works in general literature, contains sections devoted to voyages and travel, folklore, and books relating to the north country. The prices asked appear to be very reasonable.

The announcement list of forthcoming books just received from Messrs. Methuen and Co., Ltd., contains particulars of many works of scientific interest, several of which are translations. Consideration of space permits reference to only a selection of titles. Among the translations are "The Origin of the Continents and Oceans," Prof. A. Wegener, translated, from the third German edition, by J. G. A. Skerl; "The Principle of Relativity," Profs. Einstein, Lorentz, Minkowski, Sommerfeld, and Weyl, translated by Drs. G. B. Jeffrey and W. Perrett; "The New Physics," Prof. A. Haas, translated by Dr. R. W. Lawson; "Atomic Structure and Spectral Lines," Prof. A. Sommerfeld, translated by H. L. Brose; "Recent Developments in Atomic Theory," Prof. L. Graetz, translated by Dr. G. Barr; "Crystals and the Fine-structure of Matter," Prof. F. Rinne, translated by W. S. Stiles; and "The Mechanism and Physiology of Sex Determination," Prof. R. Goldschmidt, translated by Prof. W. J. Dakin. Of the English science books in the list we notice the following: "Interfacial Forces and Phenomena in Physiology," Sir William Bayliss; "A Manual of Histology," Prof. V. H. Mottram; "A Text-book of Intermediate Physics," H. Moore; and "The Vault of Heaven," Sir Richard Gregory.

Our Astronomical Column.

Meteors of March 17.—Mr. W. F. Denning writes to record that several conspicuous meteors were observed on March 17. At 7 h. 9 m. a fireball was seen from near Durham, travelling from a point considerably south of the Pleiades to α Andromedæ. Its motion was slow, and it left a trail which, however, quickly disappeared. The radiant point was probably in Canis Major, near the bright star Sirius.

At 10 h. 8 m. a rather bright meteor of first magnitude was seen by Miss A. Grace Cook at Stowmarket. It passed through the eastern region of Canis Minor and was directed from near β Geminorum. It left a train. The same meteor was seen from Bristol, and it traversed a short path between α and ζ Boötis, the direction being from β Boötis. A comparison of the observations shows the radiant to have been at 309° +76°, and that the height of the meteor was from 66 to 48 miles over the region of Epsom and Horsham. The shower in Cepheus to which the meteor belonged was seen in the third week of March, both in 1877 and 1887. At this period of the year it supplies rather bright meteors with slow motions and trains. It appears to be an annual display, and a radiant in the same position has been observed at other periods of the year, notably in August, September, and October.

The Brightening of Beta Ceti.—*L'Astronomie* for March gives a few more particulars of the observations of this star in February. Mr. William Abbott telegraphed from Athens on February 14, 10 A.M., to M. Flammarion: "Éclat subit de β Ceti, supérieur à Aldébaran." M. F. Quénisset at Juvisy glimpsed the star on February 18, but mist prevented estimation of its magnitude. But on February 23 the sky in its neighbourhood was remarkably clear, and he could observe the star from 6 P.M. till $6^h\ 25^m$ when it disappeared behind a tree near the horizon. He saw it with the naked eye in spite of the bright twilight. *It was at least of the first magnitude* (italics in original). An exact measure was impossible so near the horizon. The magnitude in "connaissance des temps" is 2·24.

On the other hand, Mr. E. O. Tancock (B.A.A. Journ. No. 5) searched for the star by day in a clear sky on February 28 and March 3 without seeing it, though he could see Mira Ceti (estimated magnitude rather fainter than 2). Beta Ceti was lower down, but he considers that he would have seen it if it had still been of magnitude 1 on those days. His observations suggest that the increase of light was short-lived.

Vesta.—Vesta, the brightest of the asteroids, is now an easy object with binoculars, in the middle of the constellation Leo. It is due south at 10 o'clock at the beginning of April. The following ephemeris, by Mr. Bawtree, is from the B.A.A. Handbook for 1923:—

Greenwich Noon.	Mag.	R.A. h. m.	N. Decl.
April 9	6·60	10 43·2	19° 20′
,, 17	6·68	10 41·2	19° 11′
,, 25	6·77	10 41·2	18° 49′

The British Astronomical Association is undertaking the work of providing ephemerides of the four brightest asteroids. The B.A.A. Journ. No. 5 contains an ephemeris of Pallas, but as this will be in a much better position for observation in two months, we defer giving its place.

Old Egyptian Water-clocks.—Several ancient time-observations, such as the statement of the equality of day and night at the equinoxes, make it clear that some form of clock was employed. It is therefore interesting to note that casts of two Egyptian water-clocks have lately been presented by the Egyptian Government to the Science Museum, South Kensington. One, from Karnak, dates from the reign of Amenhotep III. (B.C. 1415–1380); the other, from Edfu, is of the Ptolemaic Epoch; in the former, time is measured by the uniform escape of the water; in the latter, by its uniform admission. In each case there are twelve different scales, corresponding to the length of the night or day in different months. Each of these scales is divided into twelve equal parts, showing that an "hour" was at first of variable length, being one-twelfth of the length of the day or night at the particular time of year.

Claudius Ptolemy collected the observed times of the phases of a number of lunar eclipses; these were used by several investigators, including Newcomb, Cowell, and Fotheringham, in studies of the moon's secular acceleration. As the times were presumably observed with some such instruments as those now exhibited, their study is of some astronomical importance.

Research Items.

EARLY HISTORY OF THE SIOUX TRIBE.—In the Journal of the Washington Academy of Sciences (vol. xiii. No. 3), under the title of "New Light on Early History of the Siouan Peoples," Dr. J. R. Swanton produces new evidence, largely based on phonetics, of the former distribution of this race. He summarises the results of his inquiries as follows: "The occupancy of the territory of our Middle West between the great Lakes and the Ohio by Siouan tribes seems to rest on grounds almost historical. With the strong indications now at hand there seems reason to think that a close comparative study of the Siouan dialects would enable us to reconstruct the general outlines of their ancient geographical positions with considerable accuracy. If present indications are not deceptive, when that is done we shall find that they fell into four major linguistic groups: a north-eastern, consisting of the ancestors of the later Siouan tribes of Virginia, the Hidatsa, Dakota, Biloxi, and Ofo; a south-eastern, including most of the later Siouan peoples of the two Carolinas; a south-western, composed of the five tribes of Dorsey's Dhegiha group; and a north-western, Dorsey's Teiwere."

HIGH-ALTITUDE MOUNTAINEERING.—Basing his conclusions on his experiences in climbing Mount Everest, Mr. G. I. Finch discusses the equipment for high-altitude mountaineering in the *Geographical Journal* for March. Up to 21,000 ft. the climber's physical functions were practically unimpaired and good sleep and recuperation from fatigue were possible, but at 23,000 ft. sleep was fitful, appetite fell off, and there was a general loss of physical fitness. The conclusion is that at, say, 22,000 ft. acclimatisation to altitude ceases and above that height oxygen should be used, at first in small doses, and from 26,500 ft. in larger doses, but the dose must depend on the nature of the ground. It must also be remembered that oxygen increases the appetite, and due provision must be made for this. The stimulating effect of cigarette smoke was noted at 25,500 ft. Although greater heights than these were reached without the use of oxygen, Mr. Finch thinks this procedure unwise, and believes that above the acclimatisation level a man must become steadily weaker and unable to recover from fatigue unless he makes use of oxygen. The article contains also some hints on clothing, footgear, and apparatus.

NEW PLANTS UNDER CULTIVATION.—Part II. of Vol. 148 of *Curtis's Botanical Magazine* shows that figures and descriptions under the new editor, and conditions of publication, will maintain a high level. Among the plants described by Dr. Stapf, four are due to the activities of collectors in China; two new Rhododendrons, *R. sulfureum* Franch. and *R. planetum* Balf, a delightful Labiate from Yunnan named by Forrest *Dracocephalum Isabellæ*, and a small-fruited hardy apple *Malus toringoides* Hughes. Two orchids, *Maxillaria Fletcheriana* Rolfe and *Cirrhopetalum tripudians* Parish et Reichenb., two succulents, *Euphorbia anoplia* Stapf (S. Africa) and *Echinocactus undulatus* Dietr. (Mexico), two other African plants, *Amorphophallus coffeatus* Stapf and *Lachenalia convallariodora* Stapf, are described, together with one plant from the Afghan Indian frontier, *Lonicera Griffithii* Hook. f. and Thoms., a honeysuckle that seems to offer some difficulties in cultivation, although it has been grown in an unheated conservatory successfully and with very pleasing results.

BRITISH CYTOSPORA.—In the *Kew Bulletin*, No. 1 for 1923, W. B. Grove has provided descriptions of the British species of Cytospora which will be of great value for mycologists, particularly for phytopathologists, as these fungi do considerable damage, especially among fruit trees. Cytospora is the name given to a conidial form, producing upon the branches of the host plant pustules and ultimately roundish discs, from the centre of which conidial discharge is indicated by a black point or little tendril of conidia held together by mucilage. When the full life-cycle can be traced, it will probably be found that all the species can be shown to be stages in the life-history of some Pyrenomycete, such as Valsa, Valsella or Eutypella. The necessary cultural experiments, to connect these conidial stages with their specific ascophorous form, should be carried out during the next few years in the cases where the host plants are cultivated plants of value. The British locality for a large number of the 62 species described is given as Kew Gardens, presumably because suspicious twigs are more frequently removed for expert examination from Kew than from trees that are less closely examined. Mr. Grove's list will, however, be an incentive to a more general study of the British species of Cytospora.

THE OLDEST ROCKS OF MARYLAND.—Following the general trend of opinion as research progresses among pre-Cambrian rocks, Eleanora B. Knopf and Anna T. Jones ("Stratigraphy of the crystalline schists of Pennsylvania and Maryland," *Amer. Journ. Sci.*, vol. 205, p. 40, January 1923) assign a sedimentary origin to the oldest known rocks of Maryland, which are styled the Baltimore gneiss. There is no tendency to revert to the old view that gneisses were deposited from primordial hot solutions. Their layer-structure represents normal sedimentary sheets, in which a complete recrystallisation of the constituents has taken place. Some dynamic metamorphism is traced in portions of the mass; but the principal feature of alteration appears to be due to invasion by a batholitic granite magma, with consequent *lit-par-lit* injection. This fact leads the authors to write of the composite rock as an "intrusive complex of early pre-Cambrian age," an expression that surely misrepresents the general conclusion at which their work arrives. The distribution of metamorphic masses in the local Palæozoic series is anomalous, and the presence of subjacent batholitic invaders is suggested.

A GREAT STRATIGRAPHICAL SEQUENCE.—The enormous vertical sections provided by the Grand Cañon of the Colorado River in Arizona remind one of the old-fashioned geological diagrams, in which the succession of known strata was represented as continuous at one spot and based inevitably on a floor of granite. Yet even the 4000 feet of horizontal beds exposed by the stream-cut at Bass Trail tell us nothing of what went on between Cambrian and Devonian times, and include, as Mr. L. F. Noble's detailed study shows, several notable if lesser unconformities. In Professional Paper 131B, United States Geological Survey (1922), Mr. Noble does not confine himself to the Bass Trail section, of which he gives a drawing worthy of reproduction as a lecture-diagram. He provides photographic studies of various unconformities, which the casual visitor would find it difficult to trace, and concludes with the suggestive outlier of Lower and Upper Triassic strata, forming the flat-topped Cedar Mountain, two miles from the cañon edge. His discovery in 1920 of the frond of *Callipteris conferta* in the Hermit Shale is regarded

by Mr. White as definitely fixing the Permian age of that formation, which occurs 900 feet below the top bed of the Kaibab Limestone on the cañon rim. The author, despite the possibility of an unconformity at the base of the local Permian, uses the name Carboniferous rather than Permo-Carboniferous for the whole sequence, a course that seems unwise, in view of international usage. Fossils are, on the whole, rare in these splendid sections; but Pennsylvanian and Mississippian strata are both identified, above a small representative of Upper Devonian with Bothriolepis. The whole of the Gotlandian and Ordovician systems are unrepresented, and we pass down into undisturbed Upper Cambrian beds some 900 feet above the stream.

RANGER OILFIELD, TEXAS.—The Ranger Oilfield is situated in the north-west of Eastland County, Texas, and is one of the most important latter-day developments of the great Mid-Continent Oilfield region of the United States. Oil was first struck here in 1917, beginning with the bringing in of the McClesky well at 2000 barrels per day. In 1918 the best wells had an initial production of 6000-7000 barrels of oil, and the total output for that year amounted to more than 6,000,000 barrels. In 1919 the wells collectively made more than 73,000 barrels of oil per day. Since that time a steady production has been maintained, though a noticeable decline is apparently manifest at the present time. The geology and structure of the field have recently been dealt with by Frank Reeves in Bulletin 736-E of the United States Geological Survey. Production is from nine oil-sands occurring in the Strawn Series, Smethwick Shale, and Marble Falls Limestone, all of Pennsylvanian age. The structure is that of very slightly inclined strata, the tilt forming part of the general monoclinal feature of the region as a whole. Locally, low pitching anticlines have been formed which have an important bearing on the accumulation of oil in the rocks involved. The oil obtained from the Ranger field is of a high quality, of mixed base, and has an average specific gravity of 0·84; it yields about 30 per cent. of petrol. It is to be regretted that the bulletin, describing as it does one of the most important oilfields of the south Mid-Continent, is not so well illustrated as many which embrace far less noteworthy properties; in particular the index map is almost unreadable. The large structure maps included at the back of the publication are, however, unusually clear and are of great educational value apart from real technical utility.

METEOROLOGY OF THE SOUTH ATLANTIC.—Mr. H. H. Clayton makes reference in the U.S. *Monthly Weather Review* for November 1922 to a communication in the monthly bulletin of the Argentine Meteorological Office on the physical condition of the South Atlantic during summer by Mr. R. C. Mossman. The communication was to aid the relief ship sent by the Argentine Government each year to and fro between Buenos Aires and the South Orkneys to carry a party of new observers and to bring back the observers of the previous year from the most southern meteorological station in the world, which has been regularly maintained for the last twenty years. The period dealt with is comprised by December, January, and February. Charts prepared are said to show the position of the controlling high and low atmospheric pressures, and wind-roses are given for each 5° square and for each of the three months. Fog frequencies are stated to be shown for each wind direction. Allusion is especially made to the difference between a fog formed by a warm wind blowing over cold water and a fog produced by a cold wind over water at a higher temperature—the fog in the latter case extending to a much greater height, but the base not always reaching the earth's surface. The British Meteorological Office has thoroughly discussed the weather of the South Atlantic, extending to the South Orkneys, in a volume of monthly charts (M.O. No. 168) published twenty years ago.

THE ROAR OF THE MOUNTAIN.—A presidential address to the Washington Academy of Sciences was given on January 9 by Prof. W. J. Humphreys of the U.S. Weather Bureau, entitled "The Murmur of the Forest and the Roar of the Mountain," which is reproduced in Vol. 13, No. 4, of the Journal. Reference is made to historical instances recognised as of weather significance through past ages, and the roaring of the mountain is taken as an indication of a general storm within six to twelve hours. The particular region dealt with is the Gap Mills valley of Monroe County, West Virginia, but the discussion has common reference to mountain meteorology. It is shown how occasionally there are strong winds simultaneously up both sides of a high mountain ridge, and it is asserted that when there is an appreciable wind from the mountain there is often a lighter surface wind in the opposite direction up portions of the mountain itself. With tempest winds the conditions are said to be much like the Helm Wind along the west side of the Pennine range. Reference is made to the familiar singing or humming of telegraph or telephone wires. The tree and forest sounds are said not to be due to the elasticity of the twigs and branches but, as in the case of the singing telegraph wires, to the instability of the vortex sheets their obstruction introduces into the air as it rushes by them. The pitch of the æolian murmur of a forest is said to be essentially that of its average twig, and though the note of the twig may be inaudible at close quarters, the forest may often be heard miles away. Cloud and humidity are dealt with, as are also rain and snow.

A LUMINESCENT CHEMICAL CHANGE.—An interesting example of luminescence occasioned by chemical change in solution, which is said to be more intense than the usual experiment involving the oxidation of pyrogallol, is described by W. V. Evans and R. T. Dufford in the February number of the Journal of the American Chemical Society. A solution of *p*-bromophenyl magnesium bromide in ether is prepared by the Grignard reaction between 2·4 grams of magnesium and 23·6 grams of *p*-dibromobenzene in 130 c.c. of dry ether, with a little iodine. The solution exhibits luminescence which can be observed in daylight when shaken in a test-tube in an atmosphere of oxygen. The luminescence spectrum lies between λ5200 and λ3500.

INNOCUOUS METOL.—It is well known that metol, which is one of the most popular of photographic developers, suffers from the grave disadvantage that if it is allowed to come into contact with the hands it may cause persistent and exceedingly irritable sores. Mr. W. F. A. Ermen, of the British Dyestuffs Corporation, finds that almost certainly this is not due to metol itself. In a paper read before the Royal Photographic Society on March 20 (*British Journal of Photography*, March 23) Mr. Ermen gave details of the five principal methods for the manufacture of metol which the Corporation tried in 1916. A method of German origin, by the interaction of methylamine and hydroquinone, gave a very good preparation with extreme ease, but caused severe outbreaks of poisoning in both the laboratories and the works. This result was traced to the presence in the metol so prepared of the very soluble and extremely poisonous symmetrical dimethyl-paraphenylene-diamine. The metol prepared by the Lapworth process proved to be quite innocuous.

American Association Meeting at Boston.

THE seventy-sixth meeting of the American Association for the Advancement of Science was held at Boston on December 26-30. Several of the addresses delivered by presidents of sections have appeared in recent issues of *Science*, and brief accounts of some of them are subjoined.

Physics and Geometry.

In his address to Section A (Mathematics) Prof. Oswald Veblen discussed some of the aspects of postulational geometry in reference to the developments of physics during the last twenty years.

In the classical branches of physics the main elements of the abstract point of view have been implicit in them for a long time. When it is stated with sufficient clearness in physical terms what is meant by undefined elements, unproved propositions, and so on, it is often found that a physicist classifies these as truisms of little importance. So far as practical results are concerned he is justified in this attitude during the earlier and cruder stages of physical theory. But experience is showing that when the results of a more refined experimental technique force a reconsideration of fundamental assumptions, the technique of the study of these assumptions must undergo a corresponding refinement. A recent illustration is afforded by Einstein's theory of gravitation, which accounts for certain observed physical phenomena by casting aside the familiar conception of space and time in favour of a new one, which is just as self-consistent and capable of logical development.

Beginning with elementary geometry, the oldest branch of physics, there is a sequence of statements arranged in a certain logical order, but void of all physical meaning. In order to apply them to Nature, the undefined terms (points, lines, etc.) are identified as names of recognisable objects. The unproved propositions (axioms) are then given a meaning, and when this meaning can be identified with a true statement the theorems which are logical consequences are also true, and the abstract geometry takes its place as a useful branch of physics.

For kinematics it is necessary to have a theory of time: the undefined terms are "instant" and "before" or "after," and the postulates one of the sets of postulates for the linear continuum. The main theorem is that there is a continuous one-to-one correspondence between the instants of time and the numbers of a real number system.

Prof. Veblen has also formulated a set of postulates for "mass" or "substance," observing that the postulates proposed may contain both omissions and redundancies. They have merely been advanced to emphasise the fact that very little work has yet been done in this direction.

Allurements in Physics.

In his address to Section B (Physics) Prof. G. W. Stewart, of the University of Iowa, president of the section, dealt with the attractive nature of some of the problems of physics at the present time.

The investigation of atomic structure becomes so exciting that we may easily forget the absence of clearness in some of our hypotheses. The static theories have the advantage that they give clear pictures of the atoms which can be used in discussion of the physical and chemical properties of the elements as they appear in periodic groups and of the compounds they form. The orbital theories, on the other hand, have been most successful in explaining the spectra of hydrogen and helium, and, by the help of a further hypothesis, the spectra of the alkali metals. In his most recent work Bohr has departed from the simplicity of his original hypotheses and has endeavoured, by assuming electron orbits which may be circular, elliptical, or highly elliptical, and penetrate each other in many ways, to construct systems which would have the properties of the elements of the periodic table. Although this method of attacking the problem is not so rigorous, Prof. Stewart thinks it will prove more fruitful than that of the statical theories.

Acoustics receives little attention from physicists of the present day, but Prof. Stewart points out its allurements, and refers with keen appreciation to the work of the late Prof. W. C. Sabine of Harvard on the acoustics of buildings, which is only just becoming known in Great Britain. The problem of the best angle for a conical horn seems nearing solution and the conception of the instrument as a collector of sound replaced by the proper conception of it as a resonator.

Gas Ionisation and Resonance Potentials.

An address on this subject was given to Section C (Chemistry) by Prof. W. A. Noyes of the University of Chicago. The ionisation potential is the fall of potential through which an electron must move to acquire speed enough to drive out of an atom of a gas on which it impinges one of its outer electrons, known as valence electrons, and the resonance potential is the fall through which an electron must move to acquire speed enough to displace an electron of an atom from an inner to an outer ring of electrons. The two potentials should, according to the Bohr theory of the atom, be connected in a simple way with the spectrum of the gas, and many measurements have recently been made to test this theoretical conclusion. The agreement is not so satisfactory as one would desire, and there is considerable difficulty in interpreting the values of the potentials found in experiment in terms of changes in the atoms. Prof. Noyes thinks, however, that it is along these lines that our knowledge of atomic structure and of the mechanism of chemical combination will develop in the future.

Geology's Debt to the Mineral Industry.

Dr. Willet G. Miller, president of the Section E (Geology and Geography), selected as the subject of his presidential address, "Geology's Debt to the Mineral Industry." He explained that, throughout the history of its development, the progress of the science of geology has been helped to a large extent by work connected with the mineral industry. Werner and his disciples did much for the science of geology in its early development by their investigations of earth-structure as revealed in mines. William Smith, the English civil engineer, whose great work as the "father of geology" is so well known, established the principles of stratigraphical geology as a by-product of his work on engineering problems. He complained that the theory of geology was in possession of one class of men, the practice with another. Logan, the great pioneer of field studies in Canada, especially in the pre-Cambrian areas, declared that for many years he was engaged in coal-mining and copper-smelting, and that his connexion with geology related largely to its economic aspects.

After Logan's time little progress was made in

pre-Cambrian studies in Canada until after the discovery of ore-bodies at Sudbury, Cobalt, and Porcupine in Ontario. Meanwhile, on the United States side of the border such advance as was made was the outcome of studies connected with extensive and important developments in the mining of iron ore and copper ore in that region. Indeed, both in its inception and throughout its history the prime motive underlying the work of the United States Geological Survey has been an economic one; and that Survey furnishes an excellent example of the valuable scientific work made possible only by the great utility of the organisation by which it was carried out. Other examples could be given, and Dr. Miller mentions particularly that of South Africa, where the science of geology profited immensely as a result of the establishment of diamond-mining and gold-mining industries.

Dr. Miller had no difficulty at all in showing that geology owes a great debt to the mineral industry. His address will be read with much interest by that ever-increasing band of workers who feel, as he feels, that science and art should be mutually helpful and not distrustful of one another, and that a genuine scientific worker does not necessarily sacrifice dignity by carrying out investigations the results of which are likely to be useful.

Structure and Origin of the Plant Gall.

Prof. Melville T. Cook devoted his address, as president of Section G (Botany), to the subject of plant galls, and thus rendered a service to the workers in a field where literature is very scattered. In America, as in Europe, this study has been shared between entomologists, bacteriologists, mycologists, and other students of plants, and a general comprehensive account is difficult to find; from this address it appears that there is still much work to be done, progress probably having been delayed by the specialist angle from which each investigator has approached the problem.

The old idea that the gall arose as the result of a special fluid excreted by the insect as it punctured the plant has long been discredited; but although it is known that the gall tissue develops *pari passu* with the growth of the larva from the deposited egg, there is very little information as to how the larva reacts upon the plant tissue and whether the effect is produced by mechanical or chemical agencies. The reaction evidently depends in part upon the plant tissue affected, and Prof. Cook lays great stress upon the fact that it is usually only meristematic tissue which is stimulated to abnormal growth; but bearing in mind the conditions under which cork meristem arises in the plant as the result of a wound, it seems probable that in a living tissue the capacity for meristematic activity will usually be found in the proximity of the potential gall-former.

Küster, in 1911, divided gall tissues into abnormal growths, consisting only of parenchyma, the kataplasmas, and growths undergoing further differentiation of tissue, the prosoplasmas. Prof. Cook, and also Wells, have developed this original classification indicating that the more highly developed prosoplasm is a more specialised form of growth which has had its "kataplasmic" stage; the most complex types, such as the Cynipid galls, actually showing differentiation into four zones arranged concentrically around the larval irritant. Galls of fungoid or bacterial origin are also discussed in the light of this description of types of insect galls, and it will interest British botanists to find that Prof. Cook has evidently an open mind as to the analogy drawn by Dr. Erwin F. Smith between the crown gall caused by *Bacterium tumefaciens* and the malignant growths found in the animal. He is evidently inclined to regard Dr. Smith's "embryomas," arising at a distance from the original infection, as due to the disturbance of normal functional activity in the host, just as in the case of the formation of aerial tubers upon the potato as the result of the attack of *Rhizoctonia Solani*.

The Mining Industry of Canada.

Dr. J. B. Tyrrell selected the history of Canadian mining for the subject of his presidential address to Section M (Engineering). In such an address the details of so wide a subject cannot of course be dealt with, but Dr. Tyrrell gave a very clear outline of the general course of progress of the Canadian mining industry. Necessarily, in so doing he has included much interesting information on the development of Canadian metallurgy, for it is impossible to separate these two arts when tracing the history of either in any particular new country, any more than they can be divorced when considering the early history of human civilisation as a whole.

The records of Canadian mining commence as early as 1576 with Frobisher's attempt to find gold on the shores of the bay that now bears his name. Better success attended later efforts to work the commoner minerals, and the history of true mining in Canada may be said to date from the discovery of coal near Sydney, Cape Breton, in 1672, which laid the foundation of the important coal-mining industry and perhaps even more important iron and steel manufacture of the Maritime Provinces. Dr. Tyrrell chronicles the discovery of bog iron ore in the province of Quebec about the middle of the 17th century, and the erection of a blast furnace to smelt this ore in 1737. So far as iron is concerned, the history stops with the erection of charcoal furnaces in Ontario in 1810, followed by another in 1813 in Norfolk County, which remained in blast until 1847. It is to be regretted that Dr. Tyrrell did not carry this particular industry somewhat further. An interesting chapter would be furnished, for example, by the attempts to utilise the iron sands along the north shore of the St. Lawrence: these were discovered in 1767, when a Mr. Molson of Montreal built forges of the Catalan type to smelt them; but his enterprise was commercially unsuccessful though he made good iron, and it closed down after a life of nine years. The same fate attended attempts made afterwards by others, among whom was Dr. Sterry Hunt. A charcoal blast furnace was erected early in the 19th century at Londonderry, Nova Scotia, where a brand of pig-iron, which at one time had a great reputation under the name of Acadian pig-iron, was smelted from ores consisting chiefly of brown hæmatite and ankerite. At this place the first coke blast furnace in Canada was built about 1876 by the Steel Company of Canada, Ltd. Afterwards attempts were made to utilise the interesting fossil ore of Nictaux in the Annapolis Valley, Nova Scotia, but now the important iron industry of this province relies upon the magnificent Wabana ore brought across from Newfoundland.

Dr. Tyrrell describes well and clearly the modern developments in Canadian mining, which he dates from the construction of the Canadian Pacific Railway in 1885, and shows good grounds for his conclusion that in mining "our country offers a field for extensive and intensive research second to none in the world," though he justly emphasises the need for a thorough scientific training for those who are to take the lead in future developments.

Experimental Production of Green and Colourless Hydra.

W. GOETSCH, of Munich, has carried out a series of experiments on Hydra, and has published the results in some half-dozen short papers, two of which form the subject of this notice (*Die Naturwissenschaften*, pp. 202-205, 867-871, 1922). Specimens of Hydra are either green, brown, or grey, and these are regarded by most authors as belonging to distinct species or even genera, though in certain cases the brown and grey are difficult to distinguish. Goetsch points out that the brown and green may also be difficult to distinguish, for some of the former can take green algæ into their endoderm cells and form a symbiotic union similar to that long known in green Hydra.

Goetsch obtained from a warmed tank in the Botanic Garden in Nymphenburg some brown Hydra which showed pathological features, and when he fed these with algæ they developed a green colour first around the mouth, then in the foot region, and finally in the intervening portion, so that in about a fortnight the entire animal had an intense green colour. The spread of the algæ was accompanied by a progressive diminution in the size of the Hydras so that they had difficulty in capturing their prey, the reserve material of the interstitial cells degenerated, and budding ceased. These green examples disappeared from the aquarium, but a few which remained in culture vessels were fed with freshly killed Daphnia and were thus carried through their abnormal condition. The reciprocal toleration between the Hydra and the alga soon becomes an intimate association. Afterwards these Hydra produced buds containing the green algæ, and some of them showed ovaries or testes—apparently two were males and two were females.

It is impossible to determine whether the specimens are *H. attenuata* or *H. vulgaris*. The alga in these green specimens is (as in the true green Chlorohydra) a Chlorella, but differs from that in Chlorohydra in being twice as large, and in being situated in the distal end of the endoderm cells, whereas in Chlorohydra the algæ are near the base of the endoderm cells. These green examples differ further from Chlorohydra in that the symbiosis is easily lost; if the green specimens are kept in the dark or cold the green colour disappears with the exception of a small amount around the base of the tentacles, but on transferring the specimens to better conditions the algæ begin to multiply again. Specimens kept four weeks in darkness lost every trace of their algæ; the only way to make these green again was to introduce into them fresh algæ contained in crushed pieces of green specimens enclosed in the carapace of a Daphnia.

Goetsch suggests that this brown Hydra is a new mutant, and that with the origin of this mutant capable of receiving the algæ in the warm house in the Botanic Garden the conditions were for the first time favourable for the institution of the symbiosis. This union cannot be maintained through the cold of winter, and is not transmitted through the egg. In Nature the Hydras would probably not have come through the first attack by the algæ, for those in the cultures owed their survival to artificial help. If a brown and a green specimen of the same species be cut into two and a brown piece and a green piece be joined together by means of a hair, there is a gradual extension of the algæ into the previously uninfected part.

The problem of the production of colourless specimens from the green Chlorohydra has also been attacked by Goetsch. Colourless examples were obtained by Whitney by placing Chlorohydra in weak glycerine, which caused the endoderm cells to expel their algæ. Hadzi kept Chlorohydra in the dark and they produced eggs without algæ, and he thus obtained alga-free examples one of which was reared. Goetsch kept Chlorohydra under unfavourable conditions—cold, darkness, and lack of calcium—to suppress the growth of the algæ, and then liberally fed the Hydra so that their cells multiplied so quickly that the algæ could not keep pace. After a few weeks of such treatment the buds produced were of a paler colour, especially in the middle region of the body. As this is the region where asexual reproduction takes place, offspring were eventually obtained free from algæ. These whitish specimens are more feeble than green examples, and require careful treatment. A spontaneous return of colour in these white specimens has not occurred, although some of them have lived for four months in the light.

Deep green and colourless pieces were joined together and the spread of the green algæ was studied. Algæ thrust out of the endoderm cells of the green part are taken up with other food by the endoderm cells of the other part, so that after a few days the whitish part begins to exhibit a green colour, even at places distant from the junction. If a bud is formed at the junction of the two pieces it may be half green and half white. Such a bud affords strong evidence against the purely ectodermal origin of buds.

University and Educational Intelligence.

ABERDEEN.—At the spring graduation held on March 28, Sir George Adam Smith, the vice-chancellor, presiding, the degree of LL.D., *honoris causa*, was conferred on Sir William H. Beveridge, director of the London School of Economics; Dr. E. W. Hobson, Sadleirian professor of pure mathematics, University of Cambridge; Dr. W. Mackie, of Elgin, distinguished by his researches on the geology of the north-east of Scotland; Sir George H. Makin, consulting surgeon to St. Thomas's Hospital; and Prof. C. Niven, emeritus-professor of natural philosophy, University of Aberdeen.

The degree of Doctor of Science (D.Sc.) has been conferred on Dr. J. L. Rosedale for a thesis—"On the Hydrolysis of the Proteins of Flesh."

The Senatus Academicus has appointed Prof. Matthew Hay to represent the University at the Pasteur centenary celebrations to be held in Paris and Strasbourg in May.

Prof. Kruyt, Utrecht University, will deliver a university lecture in the faculty of science on May 11.

DURHAM.—Prof. H. Louis, at present professor of mining and surveying, and William Cochrane lecturer in metallurgy at Armstrong College, will vacate his appointments on September 30, 1923, on reaching the retiring age. Prof. G. Poole, of the University of Leeds, has been appointed as professor of mining. This appointment was made by the council on the recommendation of a joint committee of the College and the Durham and Northumberland Coal Trades Association. Dr. J. A. Smythe, at present senior lecturer in chemistry, will take over the William Cochrane lectureship in metallurgy; other arrangements are being made in connexion with the surveying teaching, formerly under the supervision of Prof. Louis.

Prof. R. F. A. Hoernlé, professor of philosophy, has now left England to take up his appointment as professor of philosophy in the University of Johannesburg. The council of Armstrong College will proceed

to the appointment of a successor to take up office in October.

Prof. G. H. Thomson, professor of education, and joint author with Dr. William Brown of the "Essentials of Mental Measurement," has been invited by the Teachers' College, Columbia University, New York, to spend next academic year there, delivering advanced courses on psychology. The council of Armstrong College has granted him a year's leave for this purpose.

LONDON.—Presentation Day will be held in the Royal Albert Hall, on Thursday, May 3.

The degree of D.Sc. in biochemistry has been conferred on Miss K. H. Coward, an internal student, of University College, for a thesis entitled "The Formation of Vitamin A in Plant Tissues."

Applications are invited for the Astor chair of pure mathematics tenable at University College, in succession to Prof. M. J. M. Hill, retired. The latest date for the receipt of applications, by the Academic Registrar, University of London, South Kensington, S.W.7 (12 from each candidate) is May 24.

MANCHESTER.—The trustees of the Dickinson scholarships, open to medical students and graduates of the University, have announced the conditions and regulations. The scholarships are as follows: (i.) research travelling scholarship in medicine, of the value of 300*l.* for one year, awarded annually; the scholar is required to spend at least ten months abroad and undertake there original investigation; (ii.) anatomy scholarship (25*l.* for one year), to be awarded to the most distinguished first-year anatomy student; (iii.) surgery scholarship (75*l.* for one year, offered in alternate years to a scholarship in pathology), open to medical graduates of the University; the scholar must devote himself to original investigation; and (iv.) pathology scholarship (75*l.* for one year), on the same lines as the surgery scholarship. Full particulars are to be obtained from Mr. Frank G. Hazell, Secretary to the Dickinson Trustees, The Royal Infirmary, Manchester.

OXFORD.—A fund amounting to nearly 2000*l.* has been raised to provide a memorial of the late Sir William Osler, Regius professor of medicine. It has been decided to place a memorial bronze plaque in the University Museum, and to award a medal every five years to a graduate of the University who has made some distinguished contribution to medical science. It is also desired to provide a fund to assist teachers in the University to travel for purposes connected with medical knowledge and research. For this latter object further contributions are required; these should be sent to Mr. A. P. Dodds-Parker, 2 Holywell, Oxford.

The professor of pathology, Dr. G. Dreyer, has been appointed to represent the University at the forthcoming celebration at Paris and Strasbourg of the centenary of the birth of Pasteur.

Mr. M. E. Shaw, of New College, has been elected Radcliffe travelling fellow. The Radcliffe prize has been awarded to Dr. A. D. Gardner, University College, sometime Radcliffe travelling fellow.

The Matteucci gold medal, conferred as a posthumous honour by the International Research Council at Brussels in 1919 on the late Mr. H. G. Moseley, of Trinity College, has been received at Oxford and delivered to his mother, Mrs. Sollas.

The governing body of Exeter College will hold an election in the summer term to a research fellowship of 200*l.* a year, free of income tax, tenable for 5 years. Candidates, who must be members of the University of Oxford of at least B.A. standing, must send in applications by May 15 to the rector, who will supply further details.

Societies and Academies.

LONDON.

Geological Society, February 16.—Prof. A. C. Seward, president, in the chair.—A. C. **Seward**: The earlier records of plant-life (presidential address). Reference was made to the views of Dr. Church on the origin of life in the waters of a primeval world-ocean, and on the origin of terrestrial vegetation from highly-organised Algæ transferred by emergence of portions of the earth's crust above the surface of the water. The vegetation of the land may have received additions from upraised portions of the crust at more than one epoch in the history of the earth. The course of evolution is probably more correctly illustrated by the conception of separate lines of development, than by that of a branching tree implying the common origin of the main groups of plants. The unfolding of plant-life must be considered in relation to the changing geological background. Diffusion-phenomena, as illustrated by the so-called Liesegang figures, possibly explain the origin of some of the structures which are usually attributed to organic agency. We have no knowledge of any Pre-Cambrian land-flora. The phyla of Lycopods and Ferns are regarded as independently-evolved groups. The wide geographical range of Archæopteris was emphasised, and reference was made to the difficult problems raised by the occurrence of Upper Devonian floras well within the Arctic circle, at least equal (in the variety of the plants and in the vigorous development of the vegetation) to the more southern floras of Ireland, Belgium, and other regions.

March 14.—Prof. A. C. Seward, president, in the chair.—E. M. **Anderson**: The geology of the schists of the Schichallion district of Perthshire. Between Carn Mairg and Schichallion the succession is:—graphite-schist: pebbly quartzite: mica-schist: non-pebbly quartzite: schichallion boulder-bed. Following the boulder-bed, and thus on the same side of the quartzite, are a white limestone, a banded series of siliceous and micaceous rocks, a grey carbonaceous limestone, and a slightly carbonaceous mica-schist, which may be named the grey schist. On approach to the white limestone the boulder-bed becomes highly calcareous. This conglomerate is probably a tillite, and has been partly formed from the material of the limestone. There may thus be a chronological sequence, of which the oldest visible member is the grey schist, extending upwards to the Ben Ledi grits in an adjoining part of Perthshire. In the northern part of the Schichallion district the Dalradian series is bordered by the Struan flags. The junction is probably not an unconformity, but either a normal fault which has been affected by strong horizontal movement, or else a folded thrust.—H. H. **Read**: The petrology of the Arnage district in Aberdeenshire: a study of assimilation. The modification of magmas by the incorporation of material of sedimentary origin is here termed contamination. In the Arnage mass in Aberdeenshire the sediments concerned in contamination are: (*a*) andalusite-schists and pebbly grits of the Fyvie series; and (*b*) biotite-schists and subordinate hornblende-schists of the Ellon series. The contaminated rocks occur as a roof-zone, some hundreds of feet thick, overlying a sheet of norite rich in magnesia, and are of four types. Assuming that the initial magma was normal gabbro, the contamination-process depends on reciprocal reaction between initial magma and xenoliths, whereby the magma loses magnesia and lime and becomes richer in alumina and alkalies, the final results of the reciprocal reaction being the granitic Ardlethen

type of contaminated rock and certain xenoliths extremely rich in magnesia and lime. The modified xenoliths sink in the acidified magma of the contaminated zone; they pass into the underlying sheet of initial gabbro, which becomes enriched in magnesia and lime, with the formation of the norite now seen beneath the contaminated zone. The chemical variation in the contamination-process is exactly the same as that in igneous rocks as a whole. Reciprocal reaction may play a part in magmatic differentiation, especially in the great gabbro-sheets.

Mineralogical Society, March 13.—Dr. A. Hutchinson, president, in the chair.—A. **Hutchinson**: A graphical method of correcting specific gravity determinations. A diagram is given by which the correction for air displacement and reduction to 4° C. can be read off directly.—A. **Brammall** and H. F. **Harwood**: The Dartmoor granite (Widecombe area). Field evidence and analyses support the conclusion that the granite is a composite laccolite and that four successive stages of intrusion are recorded by (1) dark and relatively basic granites scantily exposed and by certain cognate xenoliths resembling basic segregations; (2) a more acid granite which caps many tors and yields mineral evidence of having assimilated country rock; (3) a still more acid granite intrusive into the latter; (4) minor acid intrusions. Felspars, garnet, cordierite, etc. are described, and evidence for differentiation is given.—C. E. **Tilley**: Genesis of rhombic pyroxene in thermal metamorphism; mineral associations and the phase rule. Free-silica hypersthene-bearing hornfelses of sedimentary origin can be divided into a calcic and non-calcic group, and considered as derived from a normal shale hornfels by increments either of CaO, (MgO + FeO), or less commonly K_2O. Silica-poor hypersthene hornfelses can be derived from the free-silica types, and the hypersthene is then frequently accompanied by spinel. The derivation of all these hornfelses can be graphically expressed in systems of three or four components. The hypersthene is derived from the chlorite in the original sedimentary rocks subjected to metamorphism. Hypersthene arises when enstatite, augite, or amphibole-bearing igneous rocks enter contact aureoles. Rhombic pyroxene is produced by contamination of gabbroic rocks.—C. S. **Garnett**: (1) On a peculiar chlorite-rock at Ible, Derbyshire. A band in the dolerite sill at Ible is completely altered to a foliated mass of chlorite, with associated veins of fibrous chlorite (resembling chrysotile in appearance). The analyses and characters of this material are compared with those of "epichlorite." (2) The dissociation of dolomite. Dissociation is inappreciable up to 625°, and at 898° it is complete. The temperature-dissociation curve is continuous.—J. G. C. **Leech**: Occurrences of rutile, brookite, and anatase in the St. Austell granite. These minerals occur in the red pneumatolysed granites of the area, the mode of occurrence being essentially the same as that recorded for Dartmoor occurrences of these minerals.

Linnean Society, March 15.—Dr. A. Smith Woodward, president, in the chair.—J. **Parkin**: The strobilus theory of Angiospermous descent. The idea that the flower has evolved by reduction from a bisexual cone of a special type is elaborated. This Anthostrobilus is characterised by having the microsporophylls borne on the axis invariably below the megasporophylls; it is peculiar to the Angiosperms, Bennettitales, and Gnetales. From the Pteridosperms, strobilate plants arose either (1) by the segregation of the two kinds of sporophylls into unisexual cones, or (2) by their aggregation into one and the same cone. The Anthostrobilus may have been called into being through the substitution of insect-pollination for wind-pollination. The Angiosperms are regarded as a monophyletic group and the Monocotyledons as of monophyletic origin from the Dicotyledons and of Ranalian extraction. The 8-nucleate sac is taken as primitive for Angiosperms. A return to the Ranales as the starting-point for the evolutionary study of the flower is advocated.

Aristotelian Society, March 19.—Prof. A. N. Whitehead, president, in the chair.—Miss H. D. **Oakeley**: Prof. Wildon Carr's Theory of Monads. The importance as well as the difficulties of this theory lie in its attempt to combine into a unity the points of view of idealism and of creative evolution. The means by which the two viewpoints are brought into unity is the concept of reality as activity. The theory raises complex and many-sided problems in regard to a monad's knowledge, the nature of the material world, inter-monadic intercourse and the ultimate reality within or beyond experience. The problem of knowledge is conceived by Prof. Carr from the point of view of relativity and the doctrine of perspectives. The material universe results from the dichotomy of experience essential to activity, for activity can be conceived only as an opposition of antithetical forces. "Activity" is the core of the metaphysical theory. It is the reality of the monad, and its first expression is the æsthetic creative production of images. The doctrine of the monadic nature of reality is based on intuition, but Prof. Carr claims that modern science confirms his view, arguing that science must postulate that monads constitute the real, in order to make its results fully intelligible. Knowledge according to the theory must be perspective in form, and this also is supported by arguments from modern scientific relativity.

Royal Microscopical Society, March 21.—Prof. F. J. Cheshire, president, in the chair.—M. T. **Denne**: An improved apparatus for the production of photomicrographs. The apparatus consists of a bed made up of two heavy rectangular metal bars, upon which slides a carriage, one end of which is shaped to act as support for the microscope lens system, a separate microscope not being used. The carriage also bears one end of the camera bellows, and an optical bench for the below-stage apparatus. The head of the camera with dark slide fitting is fixed at one extremity of the bed itself. The eyepiece of the microscope is brought through the orifice of the plate-holder fitting, when adjustments may be made, the camera bellows being collapsed over the body of the microscope. For metallurgical work the usual vertical illuminator is employed with a right-angle prism arranged above the main optical axis. The apparatus is compact, although giving 800 mm. camera extension, and, since it is not necessary to swing the microscope out of the axis for preliminary adjustments, difficulties due to decentralisation are eliminated.—A. C. **Thaysen** and H. J. **Bunker**: The destruction of cellulose fibres and fabrics by micro-organisms and the importance of the microscope in the study of this destruction. Destruction of fibres such as cotton and flax involves vast sums of money; the United States Department of Agriculture place the annual damage to American cotton, on this account, at seventy million dollars. Different types of cotton are differently affected. All true Indian cottons appear to deteriorate quickly, at a rate which is constant. American cottons are far more resistant, but they also show a constancy in their rate of deterioration. The greater resistance of American cottons appears to be due to at least two factors: the absence of food, and some more

positive factor. This latter appears to be affected by climatic conditions, since American cottons grown in India show, on the addition of food material, an accelerated rate of deterioration. Selective breeding might possibly assist in the isolation of strains of cotton resistant to bacterial attack.—E. **Hatschek**: The standard methods of ultra-microscopy. The methods of making visible those particles small compared with the wave-length of light (100 $\mu\mu$ and less) fall into two classes: (1) illumination at right angles to the axis of the microscope (Zsigmondy-Siedentopff ultra-microscope and Jentzsch ultra-condenser), and (2) axial illumination so arranged that direct light is totally reflected at the cover glass (dark ground condensers, *e.g.* paraboloid, cardioid, concentric, etc.). The performance of the slit ultra-microscope was discussed.

Royal Meteorological Society, March 21.—Dr. C. Chree, president, in the chair.—G. M. B. **Dobson**: Characteristics of the atmosphere up to 200 km., as obtained from observations of meteors. The rate of heating and evaporation of a meteor depends on the air density. Nearly all the kinetic energy of the meteor is finally radiated as visible light, and thus observations of a meteor's total brightness and velocity give its mass. Hence from the observed characteristics of meteors it is possible to calculate the density of the air at the height of their appearance and disappearance. The rate of change of density with height will indicate the air temperature. From eye observations of meteors the temperature of the air is about 220° a. (−63° F.) up to 50 km., thus agreeing with the results of *ballon sondes*. Above 60 km. the temperature is about 300° a. (81° F.), and the density at 100 km. is about 100 times greater than that usually calculated on the assumption of a uniform temperature of 220° a. The high temperature is presumably due to the absorption of solar radiation by the air in addition to terrestrial and atmospheric radiation, due possibly to the presence of ozone formed at great heights by the sun's ultra-violet light. There is indirect evidence of an annual variation of air temperature.

DUBLIN.

Royal Dublin Society, February 27.—Prof. J. A. Scott in the chair.—P. A. **Murphy**: On the cause of rolling in potato foliage; and on some further insect carriers of the leaf-roll disease. The mechanism of rolling of potato foliage as caused by leaf-roll, and incidentally by some other diseases and injuries, is discussed. The cause of rolling in the cases investigated is the distension of the spongy parenchyma following the accumulation of carbohydrate in the leaves. The activities of a capsid (*Calocoris bipunctatus*), a jassid (*Typhlocyba ulmi*), and an aphis (*Myzus Persicæ*) which develops on the sprouts of unplanted tubers, in carrying leaf-roll are discussed. —John J. **Dowling**: The recording ultramicrometer: its theory and applications. The theoretical principles of the device, together with a description of some experimental investigations into the conditions of operation, are discussed. The degree of sensitivity attained under ordinary laboratory conditions is 10^{-7} cm.; this being strictly reproducible and the apparatus quite easy to operate. The operation of the apparatus at still higher sensitivities requires special precautions, such as screening and the like.

March 27.—Prof. J. A. Scott in the chair.—R. L. **Praeger**: Catalogue of scientific and technical periodicals in Dublin libraries. A card-index catalogue showing all the scientific periodicals available in Dublin has been prepared by a special committee. In each case the extent of the sets in each library is shown, together with any breaks which occur. Thus it is possible to ascertain if any number of any periodical, whether current or extinct, is available in Dublin, and where it is to be found. It is proposed to endeavour to improve the supply of such literature by suggesting the discontinuance of some periodicals which are unnecessarily reduplicated and their replacement by others at present unavailable.—W. R. G. **Atkins**: The hydrogen ion concentration of the soil in relation to the flower colour of *Hydrangea hortensis* W., and the availability of iron. The hydrangea produces blue flowers when grown in acid soil, since iron salts are absorbed in larger amounts and react with the pink flower pigment. Iron is absorbed by plants mainly in the ferrous condition, for at ordinary soil P_H values ferric iron is completely precipitated. Ferrous salts are not completely precipitated at $P_H 7$. The lessened solubility in alkaline soils is considered in relation to chlorosis. Iron pan formation is connected with the oxidation of the ferrous hydroxide precipitated when acid soil solution percolates to a region of higher P_H value.—H. G. **Becker** and E. F. **Pearson**: Irregularities in the rate of solution of oxygen by water. A form of apparatus is described which permits the process of absorption to be observed continuously by means of a sensitive water manometer, the temperature being maintained constant to 0·1° C. The results obtained show that during the early stages, absorption follows a logarithmic curve very closely, but after the gas-content has risen to about 70 per cent. of saturation the absorption tends to become irregular. This indicates that the force producing the slow mixing during the early stages tends to become very small, and therefore uncertain in its action towards saturation.

PARIS.

Academy of Sciences, March 12.—M. Albin Haller in the chair.—Luigi **Bianchi**: A kinematic property of W surfaces.—M. Jules Bordet was elected a foreign associate in succession to the late M. Ciamician, and M. J. Cornet corresponding member of the section of mineralogy in succession to M. W. C. Brögger, elected foreign associate.—**Mordoukhay-Boltovskoy**: The logarithm of an algebraic number.—M. **Hadamard**: Remarks on the preceding communication.—M. **Mandelbrojt**: Taylor's series with gaps.—M. **Malaval**: Hardening (of metals). Metals can be hardened not only by longitudinal extension (Seigle) but also by compression, and the latter method was applied in 1912 to a gun, with good results.—Georges **Darmois**: The local integration of Einstein's equations (interior problem).—M. **Cisotti**: Plane movements of liquids endowed with viscosity.—D. **Eginitis**: The reform of the calendar in Greece. A discussion of the political and ecclesiastical difficulties attending the reform of the calendar in Greece.—M. **de Broglie** and E. **Friedel**: The diffraction of the X-rays by smectic bodies. The smectic state is defined as one in which the molecules, having a common direction, are distributed along parallel equidistant surfaces. Such substances should act on X-rays like the system of parallel reticular planes of a crystal. In confirmation of these views experiments on the diffraction of X-rays by solutions of sodium oleate are described. Combined with the experimental figures of P. V. Wells, these results form the first direct measurement of the wave length of the X-rays starting with optical wave lengths, and without making use of either Avogadro's constant or Planck's constant.—J. **Cabrera**: The limits of K absorption of some elements. Results are given for a group of sixteen elements, mainly from the rare earths.—M. **Volmar**:

The photolysis of tartaric acid and the acid alcohols. Solutions of tartaric acid exposed to ultraviolet light give off gas containing carbon dioxide (66 per cent.), carbon monoxide (10 per cent.), hydrogen (21 per cent.), and hydrocarbons. The solution contains an aldehyde and small quantities of a substance resembling the hexoses.—Pierre **Steiner**: The ultraviolet absorption spectrum of veratrol and vanillin. The absorption curve of veratrol resembles that of pyrocatechol: the introduction of two methyl groups into the pyrocatechol molecule has only a slight influence on the spectrum.—Victor **Henri** and E. **Walter**: The law of the distribution of the bands in the ultraviolet absorption spectrum of the vapour of toluene.—Armand **Castille** and F. W. **Klingstedt**: The ultraviolet absorption spectra of benzoic acid and of the three oxybenzoic acids. The ortho- and meta-oxybenzoic acids give nearly the same spectrum, but the para acid shows marked differences in the number and appearance of the absorption bands.—M. **Bourguel**: The preparation of true acetylenic hydrocarbons. Sodium amide removes hydrobromic acid from many brominated hydrocarbons. The reaction can be followed by titrating the ammonia evolved; the yields are good, and there is no tendency to polymerisation of the acetylene derivative.—M. **Lespieau**: The dinitrile of β-oxyglutaric acid, $CN.CH_2.CH(OH).CH_2.CN$.—P. **Diénert**: Subterranean circulation of water in fissured ground.—M. **Solignac**: The tectonic of the country of the Mogods, the plateau of Hédil and of northern Bejaoua (Northern Tunis).—E. **Bauer** and A. **Danjon**: Atmospheric absorption on Mont Blanc.—Jean **Dybowski**: A new industrial force: the utilisation of the heat furnished by thermal springs. A suggestion that the hot water from thermal springs might be utilised for forcing fruit and plants under glass.—P. **Bugnon**: The number of cotyledons of Ficaria. *Ficaria ranunculoides* has been regarded by different authors as containing two, one, or no cotyledons, and the true number has an important bearing on the theory of the origin of the monocotyledons. Ficaria possesses two leaf organs having the same anatomical connexions with the root as the two cotyledons of the dicotyledonous species of the same family: the most plausible hypothesis is that Ficaria is heterocotyledonous.—Marcel **Mirande**: The nature of the secretion of the sterinoplasts of the white lily. The central body of the sterinoplasts is a lipoid solution of phytosterol.—M. **Trabut**: Carpoxeny and bud mutation in cultivated Citrus.—J. **Feytaud**: A plan of campaign against the Doryphore of the potato.—A. **Demolon** and P. **Boischot**: Researches on the assimilability of phosphatic manures. A saturated solution of carbon dioxide was used to dissolve the soluble phosphate, and special attention was given to the effect of the presence of calcium carbonate on the amounts of phosphorus extracted from various types of phosphatic manure.—H. **Hérissey**: The reversibility of the ferment action of α-d-mannosidase.—Marcel **Baudouin**: Radiography applied to the study of the lesions of prehistoric human bones. Human remains of the polished stone age have been submitted to radiographic examination with interesting results. Fractures in bones have been detected, certain congenital lesions identified, also a case of chronic osteoarthritis, and two traumatisms due to foreign bodies, one of which is undoubtedly a sharpened flint.—André **Broca** and Jean **Comandon**: The representation of movement in pictures.—Jacques **Pellegrin**: New contribution to the ichthyological fauna of the fresh waters of Morocco.—H. **Bordier**: The influence of diathermic d'Arsonvalisation on the endocrinic glands. Application to the treatment of Basedow's disease. This method of treatment, of which the technique is described, has been applied with success to several cases of exophthalmic goitre.

Diary of Societies.

SATURDAY, APRIL 7.

GILBERT WHITE FELLOWSHIP (Annual General Meeting) (at 6 Queen Square, W.C.1), at 2.—Sir David Prain: Presidential Address.

MONDAY, APRIL 9.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—A. Hiorth: Irrigation of Palestine.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

SOCIETY OF ENGINEERS, INC. (at Geological Society), at 5.30.—T. Exley-Fisher: The Work of the Labour Corps in France during the War, with Particular Reference to the 178 Labour Company.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—H. M. Fletcher: The Architecture of Provincial France.

ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Prof. C. D. Broad: The Natural Meaning of the Unconscious.

ROYAL SOCIETY OF ARTS, at 8.—E. Kilburn Scott: The Fixation of Nitrogen (1) (Cantor Lectures).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Engineers' Club, 39 Coventry Street), at 8.—S. S. Zilva and J. C. Drummond: The Cod Liver Oil Industry of Newfoundland.—E. W. Blair, T. S. Wheeler, and J. Reilly: A Study of the Separation of the Gases formed in the N-butyl-alcohol-acetone Fermentation Process.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—P. Bigelow: Geographical Influences bearing upon Japan and her Neighbours.

INSTITUTION OF RUBBER INDUSTRY (at Engineers' Club, Coventry Street).—Dr. D. F. Twiss: Rubber Pigments.

TUESDAY, APRIL 10.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Arthur Keith: The Machinery of Human Evolution (1). Nature of the Machinery.

SOCIETY FOR THE STUDY OF INEBRIETY (at Medical Society of London), at 4.—Dr. W. M. Feldman and others: Discussion on Racial Aspects of Alcoholism.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—A. E. Chambers: Potrero No. 4. A History of One of Mexico's Earliest and Largest Wells.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. G. M. Vevers: Notes on a Recent Visit to Zoological Gardens in Holland and Belgium.—Prof. K. Kostanecki: A Remnant of the Omphalo-mesenteric Arteries in the Manatee.—Dr. C. F. Sonntag: The Anatomy, Physiology, and Pathology of the Chimpanzee.

INSTITUTION OF CIVIL ENGINEERS, at 6.—A. Binns: The King George V. Dock, London.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—H. M. Cartwright: Study of Bichromated Gelatine with reference to Photogravure.—W. Clark: The Reduction Centres of a Silver Bromide Emulsion.

RÖNTGEN SOCIETY (at Institution of Electrical Engineers), at 8.15.—M. A. Codd: A New Method of Operating Induction Coils.

WEDNESDAY, APRIL 11.

ROYAL SOCIETY OF ARTS, at 4.30.—E. Parnell: The Resources and Trade of Sarawak.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—Dr. N. W. McLachlan: The Application of a Revolving Magnetic Drum to Electric Relays, Siphon Recorders, and Radio Transmitting Keys.

INSTITUTION OF AUTOMOBILE ENGINEERS, at 7.30.—C. W. J. Taffs: Railless Trolley Traction.

THURSDAY, APRIL 12.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. O. Rankine: The Transmission of Speech by Light (1).

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—A. G. Warren: The X-ray Examination of Materials.

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—F. Twyman: The Hilger Microscope Interferometer.—A. Whitwell: The Form of the Wave Surface of Refraction.—J. H. Barton: A New Research Microscope of Original Design.

INSTITUTE OF METALS (London Local Section) (Annual General Meeting) (at Institute of Marine Engineers, Inc.), at 8.—Dr. S. W. Smith: The Surface Tension of Metals.

CAMERA CLUB, at 8.15.—E. A. Robins: The Edible Crab.

FRIDAY, APRIL 13.

ROYAL ASTRONOMICAL SOCIETY, at 5.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Madder-stained Specimens illustrating the Process of Bone-growth.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—C. B. Clapham: Instrument Equipment of Aeroplanes.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—J. R. H. Weaver: Cathedrals of Northern Spain.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. W. H. Eccles: Studies from a Wireless Laboratory.

PUBLIC LECTURE.

TUESDAY, APRIL 10.

GRESHAM COLLEGE (Basinghall Street), at 6.—W. H. Wagstaff: Geometry. (Succeeding lectures on April 11, 12, and 13.)

Smithsonian Institution
APR 20 1923
National Museum

ROYAL INSTITUTION OF GREAT BRITAIN,

21 ALBEMARLE STREET, W.1.

GENERAL COURSES OF LECTURES AFTER EASTER, 1923.

At Three o'clock.

Sir ARTHUR KEITH, F.R.S., "The Machinery of Human Evolution." Tuesdays, April 10, 17, 24, May 1.

Professor A. C. SEWARD, F.R.S., "The Ice and Flowers of Greenland," and "Arctic Vegetation of Past Ages." Tuesdays, May 8, 15.

Professor W. M. FLINDERS PETRIE, F.R.S., "Discoveries in Egypt." Tuesdays, May 22, 29, June 5.

Professor A. O. RANKINE, "The Transmission of Speech by Light." Thursdays, April 12, 19.

Professor J. T. MACGREGOR-MORRIS, "Modern Electric Lamps." Thursdays, April 26, May 3, 10.

Professor E. G. COKER, F.R.S., "Engineering Problems solved by Photoelastic Methods." Thursdays, May 17, 24.

Sir WILLIAM M. BAYLISS, F.R.S., "The Nature of Enzyme Action." Thursdays, May 31, June 7.

Sir OWEN SEAMAN, "Sonnets and Ballads of Dante Rossetti." Saturdays, April 14, 21.

Dr. LEONARD L. M. WILLIAMS, "The Physical and Physiological Foundations of Character." Saturdays, April 28, May 5.

Mr. JOHN B. MCEWEN, "Dance Music," "Harmonic Evolution." "Musical Education." Saturdays, May 12, 19, 26.

Dr. ARTHUR W. HILL, F.R.S., "The Vegetation of the Andes," "The New Zealand Flora." Saturdays, June 2, 9.

Subscription (non-Members) to all Courses of Lectures (excepting the Friday Evening Discourses and the Juvenile Lectures), Four Guineas.

Subscription to a Single Course, Two Guineas or One Guinea.

The Friday meetings will begin on April 13 at 9 P.M., when Dr. W. H. ECCLES will give a Discourse on "Studies from a Wireless Laboratory." Succeeding Discourses will probably be given by Mr. W. J. S. LOCKYER, Mr. C. V. BOYS, Professor F. SODDY, Professor W. A. BONE, Mr. W. M. MORDEY, Sir ASTON WEBB, Professor H. A. LORENTZ, and Miss JOAN EVANS.

Information as to Membership and other matters connected with the Institution can be had at the Secretarial Office, 21 Albemarle Street, W.1.

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY,

SOUTH KENSINGTON, S.W.7.

DEPARTMENT OF OPTICAL ENGINEERING AND APPLIED OPTICS.

A Special Course of Six Weekly Lectures on "THE POLARISATION OF LIGHT AND SOME OF ITS TECHNICAL APPLICATIONS," by Professor F. J. CHESHIRE, C.B.E., F.Inst.P., P.R.M.S., commencing on Monday, April 30, at 6.30 P.M.

The Petrological Microscope will receive special attention in these Lectures.

For admission tickets application should be made to the REGISTRAR at the above address, or the fee may be paid at the first lecture. Fee, 10s.

UNIVERSITY OF ABERDEEN.

BLACKWELL PRIZE ESSAY.

THE BLACKWELL PRIZE of THIRTY POUNDS, open to Unrestricted Competition, will be awarded in 1924 for the Best Essay, provided the Trustees are of opinion it is of a sufficiently high standard, on "The History of the Fishing Industry of the Port of Aberdeen since 1800."

Essays must be lodged with the SECRETARY OF THE UNIVERSITY on or before January 1, 1924.

Each Essay must bear a motto, and be accompanied by a sealed envelope bearing the same motto, and enclosing the name and address of the writer.

H. J. BUTCHART, Secretary.

BEDFORD COLLEGE FOR WOMEN (UNIVERSITY OF LONDON).

POST-GRADUATE SCHOLARSHIP.

The Council of Bedford College for Women invite applications for a POST-GRADUATE SCHOLARSHIP in SCIENCE to be awarded in June 1923. Open to graduates of Bedford College only. Value £125 a year for two years.

For further information apply to the SECRETARY, Bedford College, Regent's Park, N.W.1.

UNIVERSITY OF LONDON.

DIXON FUND.

Applications for grants from the DIXON FUND for assisting scientific investigations, accompanied by the names and addresses of two references, must be made to the ACADEMIC REGISTRAR, University of London, South Kensington, S.W.7 (from whom further particulars may be obtained) before May 15, 1923.

CHELSEA POLYTECHNIC,

CHELSEA, S.W.3.

Day and Evening Courses in Science under Recognised Teachers of London University.

I. **INDUSTRIAL CHEMISTRY DEPARTMENT.** Technical Courses in Analytical and Manufacturing Chemistry, Pharmacy, Food and Drugs, A.I.C. Courses, Metallurgy, Assaying, Foundry Work, Research.

II. **INDUSTRIAL PHYSICS DEPARTMENT.** Practical work in General Physics, Applications to Industries, Metrology, Calorimetry, Illumination, Acoustics, Electrical Measurement, Research.

III. **BIOLOGICAL AND GEOLOGICAL DEPARTMENT.** Courses for B.Sc., etc., in Botany, Geology, Mineralogy, Zoology, Special Courses in Bio-chemistry, Bio-physics, Bacteriology, Physiology, Hygiene, Entomology, Plant Pathology. Course for Tropical Planters, Research.

Easter Term begins on April 17.

SIDNEY SKINNER, M.A., Principal.

Telephone: Kensington 809.

BATTERSEA POLYTECHNIC.

LONDON, S.W.11.

Principal—ROBERT H. PICKARD, D.Sc., F.R.S.

COURSES FOR WOMEN.

Full-time day courses for women preparing to be teachers of Domestic Subjects.

Preparation for posts as Institutional Matrons and Housekeepers and for colonial and home life.

Full-time day courses of training for Women Health Visitors and Infant Welfare Workers.

Evening courses of training for Sanitary Inspectors, Health Visitors, Meat and Food Inspectors, Smoke Inspectors, etc.

Day and Evening courses in Art, Music, and Domestic Science.

Hostels for Women Students. Large Athletic Ground and numerous clubs and societies.

NATIONAL UNION OF SCIENTIFIC WORKERS.

THE AIM OF THE NATIONAL UNION OF SCIENTIFIC WORKERS is to bring together into one professional organisation all qualified scientific workers, viz. :

Those engaged (*a*) In Higher Educational and Research Institutions.
(*b*) In Industry and Consultative Practice.
(*c*) In State and Municipal Scientific Departments.

Applications for membership are invited from all scientific workers with university degree or equivalent professional qualification. Further particulars may be obtained from

THE GENERAL SECRETARY, N.U.S.W., 25 Victoria Street, S.W.1.

TO SCIENTISTS AND RESEARCH STUDENTS.

THE INTERNATIONAL BIBLIOGRAPHICAL SERVICE BUREAU,

employed by British Government Departments, University Professors, etc., supplies complete Continental and American bibliographies on any scientific, literary, or medical subject. Chemical work a speciality. Extracts made.

Headquarters: Vienna. English representative: "ALEXANDRIAN," 1A Longridge Road, Earl's Court, S.W.5.

UNIVERSITY OF LEEDS.

DEPARTMENT OF MATHEMATICS.

The Council will shortly proceed to the appointment of an ASSISTANT LECTURER in the DEPARTMENT OF MATHEMATICS. Duties to begin October 1. Salary £350 to £400 a year, in accordance with qualifications and experience. It is desirable, but not essential, that the selected candidate shall possess a competent knowledge of the higher portions of some branch of Applied Mathematics. Applications, stating academic career and subjects of special study, together with testimonials (one copy) and references, should reach the REGISTRAR, The University, Leeds, on or before April 27, 1923.

Research in Animal Nutrition.

THE recent munificent gift of 100,000*l.* made by Sir Alfred Yarrow to the Royal Society is a tribute to the service of science to industry from a great manufacturer. It is somewhat astonishing, however, how little money has been gifted for research work into agricultural problems, in view of the fact that animal husbandry, with the occupations that depend directly upon it, is the most important industry in this country, and that, in spite of the large home production of animal foods, it is still necessary to import to a value of more than 200,000,000*l.* per annum without even then meeting fully the demands for some of those animal products.

We are probably correct in stating that in no other industry has so little been done in Great Britain to develop the scientific side, to find out the most economical methods of feeding, to reduce the relatively enormous mortality among many kinds of stock, to investigate the true nutritive value of the raw materials of feeding stuffs and the processes by which they are converted into the commercial finished product. It is true that Rothamsted is a monument to a brilliant pioneer in agricultural research, but for long this institute stood practically alone. It was not until the establishment of the Development Commission in 1911, which was appointed with the object of developing rural industries, that any real effort was made to improve this disastrous state of things. The Commissioners came to the very rational conclusion that one of the most essential things was a national scheme of research in agriculture.

As the result of full inquiry the Commissioners determined to establish two centres for the study of animal nutrition, one at the School of Agriculture at Cambridge under Prof. T. B. Wood, and the other at Aberdeen in connexion with the North of Scotland College of Agriculture and the University of Aberdeen. At Cambridge advantage was taken of an already existing and excellent research organisation, which was assisted financially and developed. At Aberdeen, however, a new institution had to be established. The amount of the capital outlay was estimated at 40,000*l.* to 50,000*l.*, and of this sum 20,000*l.* was obtained from the Development Commission.

In spite of this splendid grant, if it had not been for the very public-spirited action of Dr. John Quiller Rowett, who promised an initial subscription of 10,000*l.* and a further contribution if necessary, it is probable that the establishment of the institute might have been delayed for years for lack of funds. It is fitting that the name of this generous donor, who was willing to support this experimental institute before its capacity

to undertake research was proved, should be for all time associated with it. All who are interested not only directly in agriculture, but also indirectly in food production generally, are under a deep debt of gratitude to Dr. Rowett. It is pleasant to record that the example of Dr. Rowett has already stimulated an Aberdeen donor, Mr. Walter A. Reid, to give 5000*l.* towards the development of the library and the statistical department of the Rowett Institute.

The food troubles of the War ought to have brought it home to all that British agriculture was in a parlous state. Great Britain may be able to raise the finest horses and cattle in the world, but nevertheless our agriculture in general is in a backward condition. Sir Thomas Middleton before the war drew a most interesting series of comparisons showing the effect of the application of science between agriculture in Great Britain and in Germany, where the soil is inferior to ours. From each 100 acres of land the German farmer obtained 33 tons of corn to the British 15, 55 tons of potatoes to the British 11, 28 tons of milk to the British 17½, and even 4½ tons of meat to the British 4.

Research in Great Britain in other branches of science would have been in a poor state if it had had to rely in the past on support from public funds. We owe much of our outstanding position in various sciences to gifts from far-sighted private benefactors. Surely agriculture, which becomes the hobby of so many of our successful business men, ought to attract the necessary funds to assist in the investigation of problems of really national importance. There is abundant opening both at the Rowett Institute and at Cambridge for generous donors to assist, for example, by the institution of experimental farms on a large scale at these institutes. Such practical workshops as experimental farms are essential to demonstrate to the so-called "practical" agriculturist that there are ways better than his own of doing things, that will convince him, for example, that there is such a thing as the hygiene of the cowhouse and byre. Men talking and lecturing about the possibilities of doing things properly will not suffice; there must be actual demonstration of the value of the suggested change. The soil breeds an individual slow to convince, but facts tell. As Dr. Orr, the director of the Rowett Institute, has shown, even in the short time the work has been running at Aberdeen, such farms can be made to pay their way. The pig farm he established last year already shows a positive financial balance.

It must not be forgotten, too, that indirectly from these experiments on farm animals there will eventually emerge a great body of knowledge of direct use in the solution of human nutritional problems. Dr. Rowett, when conveying his donation to the Aberdeen Institute, definitely recognised this fact, and even stipulated that so far as possible the nutrition of man as well as that of animals should be kept in view.

As there is no institute or laboratory devoted to the investigation of the nutrition of man in Great Britain, these animal stations will have to be depended upon for a great deal of the information we now lack on mineral metabolism, to take a single outstanding example of a neglected field of study. We trust, therefore, that generous provision will be made for the maintenance and extension of the valuable research work on problems of nutrition being carried on at Aberdeen and Cambridge.

The King's English.

Notes on the Composition of Scientific Papers. By the Rt. Hon. Sir T. Clifford Allbutt. Third edition. Pp. xii+192. (London: Macmillan and Co., Ltd., 1923.) 6*s.* net.

SIR CLIFFORD ALLBUTT, the author of this little book, informs us in the preface that he has occasion in his capacity as a member of the Medical Faculty of the University of Cambridge to read, in the course of each academic year, some seventy or eighty theses which are presented for the degree of M.B. and about thirty which are offered for that of M.D. Of the value of such theses, as indicative of the prospective graduates' attainments or ability, there is a difference of opinion. Considering the usual age and opportunities of the candidates, and their limited professional experience, the theses are necessarily, for the most part, mere compilations culled from text-books, or from the records of cases in the medical journals. But, however limited their value, we are disposed to agree with Sir Clifford Allbutt that they serve a useful purpose. The search through the literature is of itself a salutary and desirable regimen. It serves to concentrate the student's attention on a single subject, and ends by making him a better informed man on that particular subject than he otherwise would be. Of course, much depends upon the choice of the subject. Sir Clifford's experience is that, on the whole, the candidates choose wisely. He tells us that the matter of these theses is good, often excellent. What he complains of is the manner of their presentation. In composition some are fair, and a few are good, but the greater number are written badly, some very ill indeed. "The prevailing defect of their composition is not mere inelegance: were it so, it were unworthy of educated men; it is such as to perplex, and even to travesty or to hide the author's meaning."

The purpose of Sir Clifford Allbutt's book is to

direct attention to these faults of "style" and of literary composition, in the hope that candidates for medical degrees may avoid the many solecisms which their theses too frequently display. It is easy to see how they arise. The art of literary composition is seldom a part of the school training of a youth. If it is taught at all it is too frequently dealt with by a master who has no real aptitude for literary craftsmanship, whose knowledge of our literature is limited, and whose critical faculty is not very acute. To bring out the best that is in a boy, to "enthuse" him with the subject, requires a teacher of rare gifts, of wide reading, knowledge, and experience. It is far easier to teach mathematics, or the elements of physical science, or even such subjects as history or a modern language, than it is to inculcate the best method of handling such a rich and flexible language as English in written composition. The consequence is that literary composition occupies, as a rule, a very subordinate position in the curriculum of a school, and the youth enters upon his higher education or even upon his life's work with a very limited experience of the richness and beauty of his mother-tongue and with little or no knowledge how properly to deal with it.

Sir Clifford Allbutt's strictures are based mainly upon his experience of the graduation theses of medical students, but they are no less applicable to the composition of scientific papers in general. The man of science, as a rule, springs from the same class as that which furnishes the medical man, and their upbringing and scholastic training are identical. It is therefore to be expected that they should both suffer from the same disabilities. Hence the author is fully justified in the selection of the more comprehensive title which he has attached to his work. A very limited experience of the periodical literature of science affords ample proof of the relevancy of his criticisms. Scientific memoirs are too frequently mere transcripts of laboratory journals, with no proper attempt at selection, logical arrangement, economy of expression, lucidity, unity, or simplicity—the cardinal virtues which Sir Clifford Allbutt rightly insists should characterise all literature.

The book is evidently the result of much careful study of contemporary scientific literature, and it is replete with illustrations and examples of faults in literary composition to be found in scientific communications. The author's criticism is in the main constructive. If he points out a solecism, as a rule he shows how it should be avoided. At times, although he would doubtless deprecate the implication, he appears to be a little hypercritical and over-fastidious, and some exception might justly be taken to his ruling. The fact is the English language is not standardised, and it is contrary to its genius and to its progressive nature that it should be. Its character is largely determined by use and wont, and by the example and influence of the acknowledged masters of literary craftsmanship. There is no established standard of style. "The style is the man." The styles of Johnson and Addison, of Ruskin and Carlyle are as wide apart as the poles: they are individualistic and characteristic of the men. It is this variety which serves to make our language the noble instrument that it is.

He who constitutes himself a literary censor, and takes up an *ex cathedra* attitude in the matter of literary composition, especially in the case of a language such as English, needs to be very sure of his ground and to walk warily. Years ago a certain Dean of Canterbury was constrained to publish a little book on the "Queen's English." That book was somewhat pitilessly handled by Mr. Washington Moon in a rejoinder entitled the "Dean's English." This episode should be a warning to those who would rush in where angels may well fear to tread. Sir Clifford Allbutt has certainly the courage of his opinions and is not slow to tell us of his likes and dislikes, but even he, like the great Homer himself, sometimes nods, and lays himself open to rebutting criticism. At the same time, his book is well worthy of the attention and careful study of all who seek to write correctly, and with a pious regard to the splendid inheritance they possess in their mother-tongue.

Eastern Tibet.

Travels of a Consular Officer in Eastern Tibet: together with a History of the Relations between China, Tibet, and India. By Eric Teichmann. Pp. xxiv+248+64 plates+8 maps. (Cambridge: At the University Press, 1922.) 25*s.* net.

EASTERN Tibet remains the least known part of Asia in spite of its exceptionally interesting problems. An important contribution to its geography has now been made as one of the indirect results of the British expedition to Lhasa in 1904. The Chinese then feared the annexation of Tibet to India, and to avert this danger immediately sent an agent to Eastern Tibet; in the following year, this "Amban" and his escort were massacred, and several French missionaries were murdered at their stations along the Tibetan frontier. To suppress the revolt Chao-erh-feng invaded the country, and Chinese authority was established and agents reinstalled in Lhasa.

Chao-erh-feng was a man of remarkable capacity, and he secured the personal trust of the Tibetans by a policy which protected them from the tyranny of

the lamas, and by the severity with which he punished any ill-conduct by his own soldiers. During his rule the Chinese position in Tibet was secure. When the Manchu Dynasty was tottering he was recalled eastward and made Viceroy of Szechuan. He was executed in Cheng-fu, the capital of that province, by the revolutionists in 1911, after a heroic effort to maintain the old government. The author fully recognises the genius of Chao-erh-feng, whom he describes as "one of China's greatest Empire builders," and says that "with him passed away Chinese ascendancy over Tibet." He adds that Chao-erh-feng's justice and fair dealing are still remembered. This tribute to the great Chinese administrator is the more weighty as the author's sympathies are rather pro-Tibetan.

After Chao-erh-feng's death Chinese rule in Tibet promptly collapsed. The Tibetans in 1912–13 recovered most of the lost country, and after a five years' truce resumed their eastward advance in 1918. There was then no Chinese force available for the defence of Western China, but there can be little doubt that if the Tibetans had seized some of the territory they coveted, the Chinese would reconquer it as soon as the internal difficulties in China are smoothed down. To avoid a prolonged war between Tibet and China, the British Government used its influence to secure a peaceful settlement. Mr. Eric Teichmann, then the British Consul at Ta-tsien-lu, acted as the local mediator, and in this volume he tells the story of the Tibeto-Chinese war and negotiations, and describes the journeys he made during his efforts to arrange peace. By great tact and patience he persuaded both sides to accept a temporary arrangement which may be ultimately adopted without loss of prestige to either side. He induced them to revert to the frontier which had been recognised from 1727–1905. During these negotiations Mr. Teichmann had exceptional opportunities for travel in unknown parts of Eastern Tibet. He is an enthusiastic and capable geographer, and made the best of his chances. The volume in which he records his experiences and observations will remain one of the standard works on the geography of East Central Asia.

The district including most of his routes lies north of the Ta-shueh-shan or Great Snow Mountains, which rise on the northern side of the famous road from China to Lhasa. From the foot of these mountains extends a vast tract of down country about 13,000 ft. above sea level; it is dissected by valleys from 2000 to 3000 ft. deep, and rises into high snow-covered ranges of which the heights and relations are unknown. Mr. Coales, the author's predecessor at Ta-tsien-lu, has shown that the country is largely composed of red sandstone and limestone. This view is confirmed by Mr. Teichmann; but there is no evidence as to which of four possible series this limestone belongs, and without further information as to the geological structure and trend of the snow-capped mountains, the fundamental structure of the country remains uncertain. Mr. Teichmann's careful observations are the more useful owing to the excellent index. There are numerous photographs, a series of seven sketch maps, and a large map of Eastern Tibet reprinted from the *Geographical Journal*.

J. W. G.

Hereditary Diseases of the Eye.

University of London: Francis Galton Laboratory for National Eugenics. Eugenics Laboratory Memoirs, 21. *The Treasury of Human Inheritance*. Vol. II.: Anomalies and Diseases of the Eye. Nettleship Memorial Volume. Part I.: Retinitis pigmentosa and allied diseases; Congenital stationary night-blindness; Glioma retinæ. By Julia Bell. With a Memoir of Edward Nettleship by Dr. J. B. Lawford. Pp. xv+123+26 plates. (Cambridge: At the University Press, 1922.) 45*s*. net.

ALL students of genetics will welcome the resumption of publication of "The Treasury of Human Inheritance," interrupted, like so many other scientific researches, by the War. Prof. Karl Pearson has now been able to issue Part I. of the Nettleship Memorial Volume, devoted to retinitis pigmentosa and allied diseases, congenital stationary night-blindness, and glioma retinæ. The report on and pedigrees of these diseases is preceded by a memoir of Edward Nettleship, written by his old colleague, Dr. J. B. Lawford. Nettleship was a fine example of the combination of clinician and researcher, which, to the honour of British medicine, has been frequent in this country and perhaps especially frequent in the department of ophthalmology. Dr. Lawford has well brought out Edward Nettleship's sterling qualities, which added lustre to a family distinguished in the fields of pure scholarship and philosophy. Nettleship possessed, to a very eminent degree, the patience, powers of observation, and natural sagacity which are essential to success in the investigation of problems of inheritance. His career adds one more to the numerous proofs that arduous medical practice is no barrier to distinguished success in pure science.

The composition of the work was entrusted to Dr. Julia Bell, who has acquitted herself admirably. The discussion of the genealogical material is preceded in each case by an historical and anatomical account of the anomaly in question which, while scientifically adequate and strictly impartial, is intelligible to the

educated layman. The pedigree plates maintain the very high standard of achievement set by former publications of the Galton Laboratory. With the exception of glioma retinæ—a rare and malignant disease—few of the conditions here dealt with threaten life, while nearly all of them so greatly interfere with the comfort of existence—in some cases making it impossible for the victim to follow his profession—that their recognition is frequent. It would therefore be expected that a large amount of genealogical material should be available. Such is the case, but the absolute frequency of the diseases is small, and in many instances, such as that of the classical Nougaret family, victims are by no means anxious to reveal their disability to strangers.

It is particularly appropriate that the volume should be dedicated to the memory of Nettleship, for a large share of the material relating to retinitis pigmentosa and the lion's share of the data of congenital stationary night-blindness are the product of his own researches.

"The Treasury" is planned to be a storehouse of facts, so that no complete analysis of the data is attempted; but certain interesting points are made. Attention is specially directed to two: (1) the presence of other defects in the family histories, (2) the etiological importance of consanguinity. As to (1), it would seem that each of these defects tends to occur largely as a single defect, but that if retinitis pigmentosa is associated with deafness in the stock the link is a close one. With respect to (2), consanguineous marriages are far more common in the diseased stocks than in the general population, save in the case of that form of congenital stationary night-blindness which is limited to males. In only one case, however, does the proportion of affected offspring of consanguineous marriages seem to exceed materially that found among the offspring of non-consanguineous marriages, a result differing from what has been observed in the records of deaf-mutism and albinism.

The very rare and usually fatal anomaly, glioma retinæ, scarcely lends itself to statistical treatment. However, in view of its absolute rarity—it is estimated not to furnish more than 0·03 per cent. of all patients suffering from diseases of the eye—the fact that it has been possible to compile thirty-six histories showing more than one case in a stock is strong evidence that this, too, is an hereditary defect.

In a prefatory note, Prof. Karl Pearson thanks the Medical Research Council for a grant in aid of the work, and expresses a "hope that the work as completed will be considered to have justified their support." The scientific public will have no doubt on that score; there could be few objects more worthy of national support than the preparation of scholarly and impartial records of the facts of human inheritance. Dr. Bell has, in our opinion, produced a thoroughly satisfactory monograph, which will at once take rank as a standard work while being—a quality by no means to be predicated of all standard works—adequate from both the literary and the artistic points of view.

Chemical and Physical Tables.

Tables annuelles de constantes et données numériques de chimie, de physique et de technologie. Vol. IV.: Années 1913–1914–1915–1916. Première partie. Pp. xxxii+626. Deuxième partie. Pp. xxxv+627–1377. (Paris: Gauthier-Villars et Cie.; London: Cambridge University Press; Chicago: University of Chicago Press, 1921–1922.) 2 parts, 7*l*.

FOR reasons which are not very clear, the earlier volumes of the "Tables annuelles" have not been fully used in this country; but a cursory inspection of Volume IV. will give the physico-chemical doubter cause to think, while an hour's serious use of it will convert him completely. Which of us can lay his hand on his heart and say that he has missed nothing essential to his subjects of research? Let him open these volumes and—unless he has already consulted them—he will be humbled. Landolt-Börnstein carries us up to the end of 1911; from that time onwards, no indexes or abstracts, however complete of their kind, afford a sufficient guide to the seeker after data, who must nowadays add to his scientific equipment the faculties of a British Museum historian and the time in which to exercise them.

There are here recorded the classified, clearly indexed data amassed during four years from 340 periodicals and other sources by 32 abstractors in 19 countries, collated by 27 well-known compilers who are specialists, and edited by Dr. Charles Marie (to whose devotion and enthusiasm the "Tables annuelles" so largely owes its existence and its success). The general control is vested in an executive of eight eminent physical chemists from a powerful international committee representing 23 nations.

It is obvious that to neglect the output of such an organisation as this would be sheer waste. In the writer's opinion (formed in spite of a hitherto somewhat inert attitude towards the earlier volumes) there is no library of physics and chemistry, pure or applied, which can now afford to be without this publication. The price seems high at first sight; but it is an investment which will repay itself many times, even before the next volume appears.

In the plan of the work much has, naturally, been gained from Landolt-Börnstein, but the scope is considerably wider and at the same time more detailed.

A series of practical tests in various sections shows that it is easy to trace at once the information sought; and to this end a system has been adopted in which rigidity has been tempered very wisely. There are chapters in Part II. which one might have expected to be placed near others in Part I.; for example, thermochemistry is separated from thermodynamics in this way, and cryoscopy from vapour pressures; but some change in the sequence of sections may doubtless be made hereafter, and in the meanwhile there is no obstacle to utility. The printing is clear; and with the tabulated data the compilers give sufficient indication of the experimental method used, mention any general formulæ found applicable by the author, and state the conditions quite unambiguously. The use of graphs instead of tables in dealing with subjects such, for example, as absorption-spectra, equilibrium mixtures of metals, or the ignition of gaseous mixtures, is well carried out. In chapters treating of organic compounds Richter's classification is used; and it is clear that the vexed question as to the organic or inorganic nature of calcium carbide would present no difficulty to the editor, for he provides the useful category of "Corps mixtes." This name, however, although no doubt correct in French, should certainly not be rendered in English as "mixtures." The misspellings of English authors' names are probably not more frequent than can be matched in English references to foreign literature.

Dr. Marie prints his regrets that this volume, covering 1913–1916, is only now issued; but, as in the case of Dr. Johnson's dog, the marvel is, not that it is done so well, but that it is done at all; for the difficulties during and just after the War must have been very great. That these difficulties have been passed, so that we have Volume IV., are informed of an accelerated issue of Volume V. (1917–1921), and may look for a regular progression thereafter, is a real achievement in advancing research. I. M.

Our Bookshelf.

Modern Tunneling. By David W. Brunton and John A. Davis. (New Chapters on Railroad Tunneling, by J. Vipond Davies.) Second edition, revised and enlarged. Pp. x+612. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 33*s.* net.

THE first edition of this work was published in 1914, and its contents were limited to mine and water-supply tunnels. The present edition has been revised and enlarged by Mr. John Vipond Davies, and contains new matter dealing with large-sized tunnels. The early part of the volume contains a very good discussion on the plant required in the construction of tunnels, and includes such subjects as the factors influencing the choice of prime movers, types of air compressors, surface plant generally, and methods of ventilation. This is followed by critical descriptions of the various underground appliances, such as rock-drilling machines, the methods of blasting, haulage, etc. The great development of tunnels during the last fifty years has been due to the application of high explosives and rock-drills, and this part of the subject receives adequate treatment. Details of the cost of a large number of tunnels are included, together with the speeds attained in driving them. There are two comprehensive bibliographies, and these may be regarded as an essential feature in a book on this subject and of moderate dimensions. The matter is presented in a very readable manner, and the volume will be of service not only to the engineer engaged in practice but also to the student of civil engineering.

La Force motrice électrique dans l'Industrie. Par Eugène Marec. Pp. viii+613. (Paris: Gauthier-Villars et Cie., 1922.) 55 francs.

M. MAREC'S book is written for those who, having a sound theoretical knowledge, are more concerned with the choosing and installing of electrical machines than with the manufacture of them. The operation of the finished machine is discussed mainly by describing its characteristic curves. The engineer is thus enabled to judge which type of machine will prove the most useful for the particular purpose he has in view. The various methods of installing electrical machinery in a workshop are fully described. The book will be of use to the English engineer, as it will show him the best modern French practice, and it will be helpful for him to compare it with his own. The various French methods of charging for alternating-current power will interest him. One method is to charge the consumer for the watt-hours he has consumed. In addition a further charge is made for the magnetising hours, this further charge only being zero when the consumer uses apparatus the power factor of which is unity. The latest French rules for standardising apparatus and methods in electrical engineering are given. The comparison of them with the American and English rules is instructive.

Orographical, Regional, Economic Atlas. Edited by T. Franklin. Part 4: Africa. Pp. 32. (Edinburgh: W. and A. K. Johnston, Ltd.; London: Macmillan and Co., Ltd., n.d.) 1*s.* 6*d.* net.

THIS collection of forty-seven diagrams and maps of Africa and parts of Africa is wonderfully good value. It includes a coloured orographical map of the whole of Africa and sectional maps of the same on enlarged scales. A uniform scale for these sectional maps would have been an advantage. The maps appear to be accurate and revised to date. The allocation of the Cameroons to the League of Nations on one map is apparently a slip. The atlas deserves a wide use.

The All-Electric Age. By A. G. Whyte. Pp. xiii+242. (London: Constable and Co., Ltd., 1922.) 7*s.* 6*d.*

MR. WHYTE gives an interesting and accurate account of the latest electrical developments. He has refrained from speculating about the future, but we think that if he had pointed out the directions in which advances will probably be made he would have added to the interest of the book.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Cause of Anticyclones.

IN reply to Major Goldie's letter in NATURE of March 31, p. 429, the following figures may be of interest.

Defining an anticyclone as a region where the barometric pressure exceeds 30·20 inches (1022·7 mb.), there are 52 cases of anticyclones in the British Isles during the years 1909 to 1922 inclusive in which the results of registering balloon observations are available.

Expressed as a departure from the mean for the height and date, these 52 cases give +1·6° F. at 1 km., +4·5° F. at 2 km., and +5·6° F. at 3 km. for the mean departure in an anticyclone. At 1 km. there are 18 negative values, at 2 km. there are 16, and at 3 km. there are 13. Ten instances, or only about one in five, show negative departures at each height.

For cyclones with a barometer reading below 29·40 inches (995·6 mb.) the corresponding mean figures are −6·1° F., −8·3° F., and −9·7° F., with 3, 2, and 1 positive signs respectively, out of 27 cases.

The above figures, the results of observations published by the Meteorological Office, do not seem to me to point to the conclusion that in England anticyclones are formed by pockets of cold polar air, but another test is available.

As I understand the theory of the Polar Front, polar air should be cold and have a low relative humidity; cold because it comes from a colder latitude, and dry because it is gradually warming up without a fresh supply of water and hence has a decreasing humidity. Conversely, equatorial air should be warm and nearly saturated. Where, then, polar air lies under equatorial air and forms a discontinuity, the inversion of temperature should be associated with an increase of relative humidity in the upper layer. Actually, just the reverse is the case.

I have examined the published figures for the continent, where records of the humidity are available for the years 1910 and 1911 separately; both years are consistent, and the combined result of nearly 300 observations is as follows:—

Percentage value to the nearest digit of observations in which an increase of relative humidity accompanies a temperature inversion, 0 per cent. Cases of inversion with no appreciable change of humidity, 4 per cent. Cases with distinct decrease, 36 per cent. Cases with very distinct decrease, 22 per cent. In these results both surface inversions and those over 3 km. are excluded.

Since the figures are not published on a homogeneous plan, classification is difficult, but "No appreciable change" means 5 per cent. or under, and "Distinct decrease" means a fall of 20 per cent. or more.

One solitary instance of an increase of humidity exceeding 5 per cent. (it was 6 per cent.) was found; it occurred at Vienna on December 6, 1911.

The continental figures are fully supported by many hundreds of kite ascents in England, and they prove that cases of warm damp air overlying colder and drier air are practically non-existent.

Thus it appears from the abundant observational material available that the lower layers of the atmosphere are almost always cold in a cyclone, and are usually (three cases out of four) warm in an anticyclone; also that when an inversion of temperature occurs it is nearly always associated (58 cases out of 62) with dry rather than damp air above.

W. H. DINES.

Benson, Wallingford.

Hypotheses of Continental Drift.

IN many recent discussions of Wegener's theory and of other geological hypotheses, the assumption has been freely made that any force, however small, can deform the earth to any assignable extent if only it acts long enough. To declare that this assumption is incorrect is scarcely possible, in the absence of much more accurate knowledge of the physical conditions within the earth than we at present possess; but there is substantial evidence against it.

We believe that mountains have stood for millions of years, indicating that the rocks at their feet can endure for that time stress-differences equal to the pressure at sea-level in the middle of a mountain. The strength of rocks at depths of 200 to 400 km. is almost certainly less, but no geodetic observations indicate that the strength is insufficient to support an uncompensated hill 200 metres in height; inequalities greater than this appear on the whole to be compensated, but the unexplained gravity anomalies remain almost the same whether we suppose that inequalities less than 200 metres in height are compensated or not. Other data, however, indicate that isostasy is not always perfect: Dr. Morley Davies has pointed out one, and I have shown that several otherwise uncoordinated data can be coordinated on the hypothesis that the rocks in the asthenosphere, though weaker than those near the surface, have a finite permanent strength. Accordingly, the hypothesis that the asthenosphere can be deformed to an unlimited extent by any small force acting for a long time is one to be regarded with great suspicion, and not to be accepted until it has been proved that it will account for more than appears to be explicable on the contrary hypothesis.

In conjunction with this hypothesis another is often utilised, which can be definitely stated to be inconsistent with physical knowledge: namely, that such a small force can overcome a much larger force acting for the same time in the opposite direction. In Wegener's theory, for example, not only is a small force supposed to have moved America across the Atlantic, but also the resistance of the ocean bottom to deformation is supposed to have caused the elevation of the Rocky Mountains. Now, given a sufficiently weak asthenosphere and enough time, it would be possible to twist the outside of the earth over the inside to any extent. So long as the layers of equal density remained symmetrical about the polar axis, no elevation or depression of rocks taking place, deformation could proceed undisturbed, America going steadily on its way without mountain-building or any other phenomenon observable by geologists. In order that mountain-building may take place, however, energy must be supplied to raise and lower the rocks affected against gravity; and to keep them in position, in spite of the tendency of gravity to restore the symmetrical form, the force required must be enough to overcome gravity and the strength of the surface rocks. The minimum stress needed to account for mountain-building is therefore greater than the pressure due to the weight of the mountain. Tidal friction and differences between the values of gravity at the tops and bottoms of continents are capable of producing stresses of

the order of 10^{-5} dynes per sq. cm., whereas to elevate the Rockies something like 10^{9} dynes per sq. cm. would be required.

A hypothesis that may be of use in accounting for continental drift, if the latter is considered to be indicated by the geological evidence, is based on Jeans's proof (Proc. Roy. Soc. 93, 1917, 413-417) that the earth is stable with regard to first harmonic deformations. The fact that most of the land is in one hemisphere indicates that a first harmonic deformation exists, and must therefore be tending to die down; the only possible means of destroying the asymmetry being for the continents to break up and spread out so as to get as far apart as possible. If, then, we are prepared to admit that the continents were once all united into one mass, it is probable that they would have broken up and separated widely, since the stresses in them must have been comparable with the pressure at sea-level due to the weight of a continent, which is at any rate a moderate fraction of the strength of rocks. Wegener's suggestion that India has moved towards the main mass is, of course, inconsistent with this hypothesis.

The possibility that the continents were formerly united has been regarded by Mr. Crook (NATURE, February 24, p. 255) as in harmony with Osmond Fisher's theory of the origin of the Pacific. The latter theory, however, is open to a serious objection. The birth of the moon on the resonance theory would require a violent distortion of the earth, sufficient to shatter into fragments any crust that might have already been formed, and these would distribute themselves symmetrically over the liquid interior at once instead of waiting a thousand million years to do it.

Prof. Sollas's suggestion, mentioned by Dr. Evans in NATURE of March 24, p. 393, that there are traces in the earth of the incipient formation of a second satellite, is not in quantitative accordance with the resonance theory of the origin of the moon. It is practically certain that the earth-moon system, when combined into one body, did not rotate sufficiently fast for instability, but it is just possible that it could have rotated fast enough for resonance to magnify the solar semidiurnal tide to such an extent as to rupture the mass into two parts. If the moon was formed in this way, however, it must have taken away with it so much angular momentum that the earth could never again have approached conditions suitable for either resonance or instability.

HAROLD JEFFREYS.
St. John's College, Cambridge.

The Life-Cycle of the Eel in Relation to Wegener's Hypothesis.

THE argument in Dr. Wemyss Fulton's very interesting letter in NATURE of March 17, p. 359, must be divided into two parts. First, it is pointed out that the gradual recession of the east and west coast-lines of the North Atlantic Ocean from one another would explain in a very satisfactory manner the evolution of the amazing migrations of the larval eel. Secondly, it is assumed that Wegener's continental drift is the only method of effecting that gradual recession. It is possible to concur heartily with the first thesis, without admitting the second.

Suess explained the North Atlantic Ocean as having been formed, during the later ages of the Cainozoic era, by successive foundering of portions of a pre-existing land surface. Except that the recession of the two coasts would then have been spasmodic instead of continuous, the general result from the point of view of the inhabitants of the sea would be just the same as if the two continents were drifting apart. While acknowledging our indebtedness to Dr. Fulton for pointing out how the life-history of the eel fits in with the other evidences of a gradually widening Atlantic, we need not admit that these wonderful migrations prove continental drift any more than the migration of birds across the Mediterranean proves that Africa has drifted away from Europe.

The Combination between Oxygen and Hæmoglobin, and the Criteria of Adsorption.

HÆMOGLOBIN combines with oxygen approximately in the ratio of 16,670 to 32, by weight, as was shown by Peters (*Journ. of Physiol.*, vol. 44, p. 131). It is clear, then, that in solution the particle of hæmoglobin is very much larger than the particle of oxygen which combines with it. If one might assume that the densities and shapes of the particles were similar, then their surfaces would be in the ratio 64 to 1; in any case, and whatever the degree of aggregation of the particles, probably only a very small part of the surface of the hæmoglobin particles can be actually covered by oxygen when combination ceases at the stage of oxy-hæmoglobin.

This shows that the attraction of hæmoglobin for oxygen is a highly localised property of the hæmoglobin particles. For if this attraction were more or less evenly distributed over the surface, it would be satisfied only to a small extent, when a small part of the surface was covered, and at higher concentrations of oxygen than those which are found experimentally to give saturation with oxygen, more oxygen would be taken up.

Taking the thermal motions of the particles into account does not affect this argument, since the movements of the particles according to the laws of the kinetic theory do not affect their surface areas.

Now, if the attraction of hæmoglobin for oxygen is of such a character that it is satisfied when only a small portion of the surface is covered, it seems impossible to regard this combination as a case of adsorption.

The criteria of adsorption are perhaps not yet so well defined as could be wished, if differences of opinion as to whether a given process should be classified as adsorption or not are to be avoided. I am inclined to think that a process is rightly classified as adsorption, *if the substance taken up by the surface continues to be taken up until the whole surface is uniformly covered*, but not otherwise. Covering the surface uniformly is of course meant in the sense in which a gas or homogeneous solid is said to fill space uniformly; that is, uniformly to a being armed with a microscope to which individual atoms are small.

This definition is both definite theoretically, and in accordance with common conceptions of adsorption. It is difficult, indeed, to see what other definition is possible in the present state of knowledge. It is perhaps, however, desirable to state the definition clearly; although, as I feel it must have been present, whether formulated or accepted as self-evident, to the minds of many workers on adsorption, no sort of novelty is claimed for it here.

A definition of adsorption based on the nature or quality of the forces attracting the adsorbed substance,

is now impossible, since it appears proved by Langmuir's work that there is no difficulty in accounting both qualitatively and quantitatively for many cases of adsorption, by means of the already very familiar forces which cause combination between metals and oxygen to form oxides, or the forces which bring about solution.

Obviously adsorption cannot be defined as "that which occurs at the surface of a colloid"; since colloids themselves are not yet a well-defined class of substances, and indeed the best studied cases of adsorption are at plane interfaces, not at the surfaces of colloids.

With the definition of adsorption proposed, a process would be excluded if, as with hæmoglobin and oxygen, combination occurs only at some defined locality on the surface. Similarly, the ordinary reactions of organic chemistry will be excluded, as they should be, since the substances taken up go to definite atomic groupings in the molecule. The combination of oxygen with hæmoglobin is seen to belong to the same class as most organic reactions.

It remains to examine whether the definition is practically applicable to known cases of adsorption, as well as theoretically justified; and whether, in the case of oxygen and hæmoglobin, the arguments originally put forward in support of the adsorption process are cogent enough to override the definition.

All cases of adsorption, from a gaseous phase, or from solution, on plane, or nearly plane, interfaces, are obviously compatible with the definition, since the common method of calculating the amount of adsorption assumes uniformity of distribution on the surface, and the results are generally expressed per sq. cm. of interface.

In the cases of adsorption on colloidal surfaces, when the extent of surface is usually not known, and the adsorption is expressed per gram of adsorbent, the definition is probably also applicable. Mecklenburg (*Zeitsch. f. physikal. Chemie*, vol. 83, p. 622) described experiments showing in several cases that the adsorption on different specimens of the same adsorbent, prepared, however, under different conditions, varied in a precisely similar way with concentration for each adsorbent, but the total amount adsorbed per gram was proportional to a factor in each case, this factor being presumably proportional to the area of the adsorbent.

In proposing the theory that the oxygen in oxy-hæmoglobin is held by adsorption, Wo. Ostwald (*Koll. Zeitsch.*, vol. 2, pp. 264, 294) based the argument on two supposed facts: first, that no definite saturation point of oxygen with hæmoglobin could be found, a fact now shown to be incorrect; and, second, that the amount of oxygen taken up at different pressures could be fairly accurately represented, under certain conditions, by the so-called "adsorption isotherm," $y = kc^n$ (y = amount taken up, c = concentration of oxygen).

The mere fact that the variation of the amount taken up fits the "adsorption isotherm" does not seem now to be a sufficient ground for classing a process as adsorption. The "isotherm" has, until quite recently, been an empirical fact without theoretical explanation; and not only does it contain two independent arbitrary constants, which makes the fitting of a set of experimental data easier than would be the case otherwise; but also it is, at the best, usually only accurate at low concentrations, divergences being found at higher concentrations.

A more accurate equation relating amount adsorbed to concentration has been deduced recently (Henry, *Phil. Mag.*, vol. 44, p. 689, 1922) on the assumptions of a small range of molecular attraction and a monomolecular adsorbed layer, using well-established equations of the kinetic theory; and the author also gives a derivation of the "adsorption isotherm" on theoretical grounds. It would seem undesirable, however, to use the form of the relation between amount adsorbed and concentration as a criterion of adsorption, for this relation can never be a very simple conception, depending as it does on so many factors; but nothing could be simpler than to conceive of a surface as possessing either localised or diffuse attraction for a substance it takes up. It may be that in some instances it is not yet possible to form any estimate of the fraction of the surface covered; yet as accurate knowledge of the dimensions of molecules and of their orientation on surfaces accumulates, the applicability of the criterion here suggested will increase. I have tried to show, however, that it is already more generally applicable than any other.

Labour and Science in Industry.

THE article by "F. S. M." under this heading in NATURE of March 24, p. 385, emboldens me to inquire whether the time has not come for a really searching scientific re-examination of the natural fundamental basis of the economic system under which we perish. That it is necessary to ask such a question as that in this article, whether, after a century's unparalleled progress in the domination of the forces of Nature and the fertile labours of inventors and producers, the average lot of the people is really better than it was in consequence, suggests a certain lack of scientific imagination. The question which many thoughtful people are now asking themselves, and which a few scientific men at least should have asked before the War, is not whether the material lot of the people is up to what it was before the use of science, but why is it not vastly improved. What kind of a civilisation ought to be the result, if science were directed in accordance with natural laws to the constructive purposes of life, rather than only so for the purposes of mutual destruction? Civilisation can scarcely revert in peace-time to economic law, in which the tokens of wealth usurp the place of reality, without raising the very general aspiration that the advantages of war and peace might be combined by proceeding according to natural laws in peace-time.

The first economists, the French Physiocrats, did make an effort to base their system on the laws of Nature, and in their doctrine, that the origin of wealth was the land, and in the later doctrine of Marx, that it was in human labour, certain obvious elements of natural truth were embodied. But in the present system there is no natural truth obvious at all. It is an offence against common sense. The production of wealth to-day is a relatively finished science, in which probably little that is fundamental remains unknown; whereas a century ago it was an empirical art as different from the present science as astronomy is from astrology or chemistry from alchemy. But the science of distributing the product—that is, the science of token wealth—is so little understood that the most incredible consequences are accepted as natural and inevitable.

In a natural community, if people were short of the necessities of existence, and knew how, they would produce and consume them. In ours, with the return to conditions of peace and victory, they are idle by the million and deteriorate mentally, morally, and physically, dumbly acquiescent in the requirements of a system no one pretends to understand. If one asks why, it is because of certain conventions with regard to bits of metal and paper to which we have all

been born and brought up, but to which probably not one in a hundred, even among scientific men, has given two minutes' original thought.

The great clarification of ideas which distinguishes modern science, and especially physical science, ought not to stop short of this most vital and fundamental problem which so menaces the well-being of the community. It is, indeed, a most fascinating problem for its own sake. The mathematician would enlarge his knowledge of the consequences of a mistake in sign in a field where such mistakes are of fearful import to whole nations, and the physicist, of a perpetual-motion machine fallacy underlying and destroying the hopes, not of a half-crazy would-be mechanic, but of a half-crazy would-be mechanical civilisation. In his well-known book, "Instincts of the Herd," Mr. Trotter has put one obvious point inimitably. "It is this survival, so to say, of the waggoner upon the foot-plate of an express engine, which has made the modern history of nations a series of such breathless adventures and hairbreadth escapes." I venture to suggest that the survival of the herd-instincts of the waggoner in an express age applies as much to those who have built the express as to those who try to drive it.

The British Association naturally suggests itself as providing the proper platform for this proposed re-examination of the physical basis of our economic system, since it has an Economics Section which, no doubt, would welcome as eagerly as the public the introduction of an element of science into its proceedings. One needs to be only a casual observer of the trend of events to know that the public, thoroughly alarmed by the consequences of peace, and fearfully awaiting asphyxiation in the next war, would take an interest in this question that would rival that of the palmy days of Huxley and the Bishops.

FREDERICK SODDY.

WE shall all sympathise with Prof. Soddy's desire that our industrial system should give a state of society in which the material lot of the people should be "vastly improved" by the application of science. We should differ from him in various degrees as to the extent to which this has been already secured, and the means which should be taken to accelerate the process. I gave in the article quoted some reasons for believing that considerable improvement had taken place: it seems, in fact, untrue to say that "we are perishing" under our present economic system. The only country which can be said to have come near to "perishing" is Russia, which attempted entirely to discard the system and is now, after a desperate experience, painfully and slowly retracing her steps. The next most seriously distressed country in the world is China, which has never attained to our modern industrial system.

By all means enlist the Economics Section of the British Association in a discussion of the problem—or rather the host of problems—involved. But do not antagonise the Section at starting by suggesting that it would be a good thing to introduce "an element of science into its proceedings." The Section has been proceeding on that assumption for a good many years now.

F. S. M.

Tactile Vision of Insects and Arachnida.

WITH reference to Commander Hilton Young's suggestion noted on p. 409 of NATURE for March 24, it may possibly be of interest to record the conclusion at which I and my colleagues arrived, when engaged, two years ago, in research on the so-called eyes in insects and arachnida. In all the species studied, including the house-fly and red ants among the former, the house spider (*Tegenaria domestica*) and many of the Epeiræ among the latter, we were forced to the conclusion that the organs generally known as eyes do not act as organs of vision. What their main purpose is, was never *certainly* determined by us; but the many phenomena which were studied as evidence of sight could all be reduced to *touch* sensations. For example, to take perhaps the simplest illustration, if the hand be slowly advanced towards a fly on a window-pane, the insect, if it be a vigorous specimen, will evade the caress. But if the hand be advanced towards the fly when the insect is on the opposite side of the glass to the hand, it may often be necessary to tap severely in order to disturb its wanderings.

Apart from air currents due to the motion of the hand, and possibly some convection currents due to the heat of the same, it is difficult to afford any other satisfactory explanation of this simple phenomenon, which any one can examine for himself with the greatest of ease.

The Resonance Theory of Hearing.

THE difficulty expressed by Sir James Barrett in NATURE of March 24, p. 396, is probably more apparent than real. If attention is focussed on the relative dimensions of the various parts of the cochlea rather than their actual sizes, I think that the range of analysis can be explained.

In the short compass of a letter I cannot deal with a full consideration of the analytical mechanism of the cochlea. A variation in pressure applied to the *fenestra ovalis*, if it is to cause a movement of the basilar membrane, must cause movement of the liquids in the cochlea. The impedance due to the inertia of the liquid is considered by Mr. Wilkinson as a "load" on the vibrating strings. In all considerations of the action of the cochlea the influence of the viscosity of the liquid has been overlooked (see *Philosophical Magazine*, 1922, vol. 43, p. 349). The friction of the liquid against the walls of the cochlea impedes the movement of the liquid so that if the diameter of the cochlea were uniform the resistance would be proportional to the distance from the *fenestra ovalis*. As the cochlea becomes narrower this is a safe assumption. If the highest audible note acts on the basilar membrane 5 μ from the commencement of the cochlea, the ratio of the impedance due to viscosity of this highest note to the lowest note might be 35,000 to 5. This is approximately the ratio given by Mr. Wilkinson without the assumption of any difference in tension in the fibres of the basilar membrane. I do not wish to imply that there is no difference in tension, but the greater bulk of the spiral ligament may be merely to resist a greater strain, and is not necessarily an indication of a greater initial tension.

If one wishes to look at this subject from the point of view of resonance, the effect of viscosity can be illustrated by narrowing the orifice of an air resonator. This lowers the note, just as the viscosity makes the note lower for the distal end of the cochlea, but the viscosity of a liquid will be much more important than the viscosity of a gas. Viscosity, however, is only one of the factors concerned in sound analysis.

The Sun-Cult in Ancient Egypt.

By Aylward M. Blackman, D.Litt.

I.

THE recent discovery of Tut'enkhamūn's tomb has naturally aroused a great deal of interest in the attempt made by that king's father-in-law, Ōkhnatōn, to establish a monotheistic form of sun-worship as the State religion of Egypt, and indeed of the whole Egyptian empire. Properly to appreciate this very striking phase of Egyptian religious thought, it is necessary to have some knowledge of the old "orthodox" sun-cult, the State religion of Egypt, since at any rate the sixth, and possibly the third dynasty—a cult which can be traced back to the very dawn of Egyptian history.

The centre of this ancient sun-cult was On, the Heliopolis of the Greek writers, a city which lay close to Memphis and the site of modern Cairo. Heliopolis was almost certainly the political centre of a united Egypt in the predynastic period, though at a time not necessarily long anterior to the beginning of the first dynasty and the founding of Memphis by Menes. The predynastic king of Heliopolis was high-priest of his city-god, the sun-god Rē'-Atum, and was also regarded as his embodiment. Immense influence was exercised by Heliopolis upon Egyptian theology and ideas in general, and even when Heliopolis ceased to be the actual capital of Egypt, the Egyptian king was still regarded as the embodiment of the sun-god and his high-priest, and Rē'-Atum still maintained his place as the State-god. Owing to the religious and political ascendancy of Heliopolis, a number of the local provincial gods were identified with the sun-god by their priests in order to enhance their prestige. Of course, this identification was particularly likely to take place when what was once a provincial town became the centre of government, as did Heracleopolis at the beginning of the ninth, and Thebes at the beginning of the eleventh dynasty.

As a result of their being identified with the Heliopolitan sun-god, and owing to the great prestige, and, no doubt in early times, superior culture, of Heliopolis, the temples erected for the worship of the solarised local gods were copies of the Heliopolitan sun-temple; moreover the liturgy celebrated therein in honour of these divinities was that celebrated in honour of their Heliopolitan prototype. In course of time the Heliopolitan form of temple was universally adopted in Egypt, and also, by a natural process, the Heliopolitan liturgy came to be celebrated in honour of every important god and goddess throughout the length and breadth of the land. This remarkable uniformity in temple architecture and in worship seems to have prevailed so far back as the old kingdom, about 2900 to 2475 B.C.

The king of Egypt, as we have seen, was the high-priest of the sun-god. He was also high-priest of all the local divinities of Egypt, and in this capacity he celebrated, or rather was supposed to celebrate, the liturgy in every Egyptian temple. His relations with the solarised divinities were of course practically the same as his relations with the Heliopolitan sun-god himself, a circumstance which naturally must have influenced his relations with other divinities and must have helped forward greatly the solarisation of all Egyptian temple-worship.

What, it may be asked, were the ideas of these ancient sun-worshippers as to the nature and character of their god? The most outstanding of all the qualities attributed to the sun-god by the Heliopolitan priests is his righteousness. The sun-god is not only represented as loving righteousness and truth and hating iniquity, but also it was said that he it was who "fashioned righteousness." Righteousness is so much a part of the god's being that he is said to live (*i.e.* feed) on it, just as Hapi the Nile-god is said to live on fish! This righteous god demanded righteousness in his worshippers also, and before the Osirianisation of the Egyptian conceptions of the life after death, a process which they underwent in the period between the end of the Old and the beginning of the Middle Kingdom (about 2475 to 2160 B.C.), the sun-god was regarded as the judge of the dead, in which capacity certain texts represent him as weighing righteousness in a balance, *i.e.* testing the righteousness of the dead.

Now the king of Egypt (in the first instance the king of Heliopolis) was thought to be, as we have seen, the embodiment of the sun-god. Accordingly, like his divine prototype he was supposed to be the upholder of righteousness, truth, and justice. But the close association of the king with the god not only associated the god's righteousness with the king: it also associated the kingship with the god. Thus the sun-god, who is represented in the myths as the first king of Egypt, came to be regarded as the prototype of all Egyptian sovereigns, the ideally righteous king, the pattern of all would-be righteous Pharaohs. In a literary composition of the Feudal Age, describing the miserable plight of Egypt under the rule of a weak Pharaoh, a sage contrasts the prevailing unhappy conditions with the state of affairs in that far-off golden age when the sun-god, the ideal king, ruled over Egypt. He speaks of the sun-god as "the shepherd (lit. herdsman) of all men, with no evil in his heart." "Where is he to-day?" he asks. "Does he sleep perchance? Behold his might is not seen!"

Purity, and particularly physical purity, was another attribute of the sun-god. Everything connected with him must, it was maintained, be pure, and only those who were pure could approach him. Consequently lustral washing was a marked feature of the sun-cult, no priest being able to enter the sun-temple (eventually any temple) to officiate until he had undergone purification. Even the sun-god himself is represented as washing or being washed every morning in some mythological lake or pool before appearing above the eastern horizon.

Now according to one conception, the sun-god was reborn every morning, having been born in the first instance, be it noted, out of the waters of the celestial ocean. Naturally enough, therefore, his daily rebirth came to be associated with his daily lustration, and he was supposed to be reborn every day at dawn as the result of washing or being washed in the waters of this or that sacred pool. In accordance with this concep-

tion, an early and important episode in the liturgy, which was celebrated every day at dawn in all Egyptian temples (in the first instance, of course, the Heliopolitan sun-temple), was the washing or sprinkling of the divinity's (originally the sun-god's) cultus-image with water, in imitation of the sun-god's supposed daily matutinal lustration.

The Heliopolitan king, the sun-god's embodiment, was, as already stated, his high-priest, and in this capacity he entered, or was supposed to enter, the sun-temple every day at dawn to celebrate the liturgy. Before he entered the god's presence he had, like every other priest, to undergo purification, but in his capacity of embodiment of the sun-god he was conceived of as reborn as the result of his ceremonial washing, just as was his divine prototype. As we shall see, the king was also regarded as the son of the sun-god, and was thus thought of as rebegotten as well as reborn through the agency of the lustral water, this being identified with the sun-god's own efflux, the very efflux with which he had brought into being his two children, Shu and Tefēnet. The king's lustral washing took place in an adjunct of the sun-temple, called the House of the Morning, so named on account of the very early hour at which this ceremony took place. The king not only underwent lustration in this chamber, but he was also robed, anointed, and crowned there, invested with the royal insignia, and apparently also presented with a light repast, after which proceedings he was ready to enter the temple to officiate.

The consort assigned to the Heliopolitan sun-god by his priests was Ḥathor, a goddess who was especially associated with music and dancing. The queen, as wife of the high-priest of the sun-god, was, in accordance with Egyptian custom, that god's high-priestess; moreover as wife of the embodiment of the sun-god she was considered to be the god's earthly wife, and so was identified with Ḥathor. Like her divine prototype she was associated with music, and it was her function to sing and rattle her sistrum while her husband, the high-priest, celebrated the liturgy.

A notable feature of the worship of Ḥathor was the performances of her musician priestesses, who were attached to her temple in large numbers. These performances consisted in dancing to the accompaniment of the rattling of sistra and the beating of single-membrane drums. Since Ḥathor was assigned to the sun-god as his wife, musician-priestesses were attached to his temple, and their dancing, singing, and playing thus became a feature of the sun-cult—eventually of all the solarised cults of Egypt. Over these musician-priestesses in the provincial temples presided the high-priestess, the wife of the high-priest, who, as inscriptions occurring in several temples explicitly state, was regarded as the wife of the god, and was as such identified with Ḥathor—the god himself being identified with the sun-god. The musician-priestesses attached to the great solar or solarised temple at the capital were, of course, presided over by the queen, the earthly counterpart of Ḥathor *par excellence*. These musician-priestesses of Ḥathor consciously impersonated Ḥathor in their performances, and are actually spoken of as Ḥathors. Thus not only the high-priestess was identified with Ḥathor, but the musician-priestesses over whom she presided were designated Ḥathors also.

Since the chief musician-priestess—at the capital the queen, or in the provinces the local high-priest's wife—was regarded as the god's earthly consort, the ordinary musician-priestesses were reckoned to be his concubines, in which connexion it is interesting to note that the Temple of Luxor, which was dedicated to the solarised Theban Amūn, was known as the Southern Ḥarīm of Amūn; so it was possibly the headquarters of that god's concubines.

Owing to the queen holding the position of wife of the sun-god, her son, the future king, naturally came to be regarded as the actual physical son of that divinity, the explanation of this wondrous happening being that the god had intercourse with the queen by incorporating himself in the reigning Pharaoh.

A brief description must now be given of an ordinary Egyptian temple, and some account of the ideas which the Egyptians entertained with regard to it, all of which will show effectually how preponderating was the influence of Heliopolis in all matters religious, and how complete was the process of solarisation which Egyptian temple-worship and all its accessories had undergone, certainly before the end of the Old Kingdom, possibly at a much earlier date.

A great ornamental gateway flanked by two towers, commonly called a pylon, admitted to an open court surrounded by a colonnade. Behind this court was the hypostyle or pillared hall, and behind it again, buried in profoundest darkness, lay the sanctuary, containing the cultus-image of the divinity to whom the temple was dedicated. In adjoining rooms were enshrined the images of the co-templar divinities. Yet other rooms served as store-chambers for the sacred utensils and vestments, or for the performance of special ceremonies.

Owing to the prevailing solar influence, Egyptian temples, certainly in early times and often later, were orientated east and west, so that the rising sun at the equinoxes might light up their dark interiors. Indeed, according to the current Egyptian conception, it was the sun-god before all others who dwelt in every temple, which was regarded as a small replica of heaven itself. Thus a favourite description of a temple is that it is "like heaven in its interior, while Rē' (the sun-god) rises within it."

Against the eastern face of either of the above-mentioned pylon-towers were erected two or four, sometimes even five, tall masts—four to ten in all—from the tops of which fluttered white, green, blue, and red flags. These towers themselves were equated with the two sisters Isis and Nephthys, who were regarded as a pair of midwives lifting up the newly-born sun into the sky every morning.

In front of the pylon there generally stood two obelisks, one on either side of the gateway. The obelisk, or rather the pyramidion on top, was closely connected with the sun-cult, being a replica of the sacred *benben*-stone in the temple at Heliopolis. This stone was the emblem of the sun-god, one of the forms under which he was worshipped, and on it he was said to have sat when he begat of himself the god Shu and the goddess Tefēnet.

Colossal statues of the royal founder or benefactor of the temple were often erected in front of the pylon beside the obelisks. Other statues of the king, repre-

senting him either in the guise of a worshipper or offerer, or as just standing or seated, were set up in various parts of the temple. Through the medium of these statues, which to the Egyptian mind were very closely connected with the person they represented (that person being regarded as immanent in them), the king could, according to the character of the statue, function perpetually either as worshipper or offerer, or else as the recipient of worship and offerings.

In the main sanctuary, and in the sanctuary of each of the co-templar divinities, was a shrine containing the cultus-image, which was as a rule quite small—sixteen inches to four feet in height—and made of wood. Sometimes the shrine was a monolithic naos set up against the back wall of the sanctuary, with a bronze frame inserted in front fitted with double doors. More often the shrine was in the form of a boat, which rested upon an altar-like stone pedestal, the place where it stood being designated "the great place." In the centre of the boat, covered with a veil, was a cabin containing the image. Poles were attached to these boats so that they might be carried in procession, the number of priests who supported them varying from eight to twenty-four, or even twenty-six. In the sanctuary of the Heliopolitan sun-temple there were two such boat-shrines, representing the morning- and evening-barque of the sun-god. The boat-shrine is undoubtedly of solar origin, for it was the sun-god in particular who was conceived of as sailing across the sky in a boat.

The sanctuary, or else the actual naos containing the image, is often designated "Heaven" or the "Horizon" in inscriptions, and one of the titles borne by the high-priest of the solarised Theban Amūn was "Opener of the Doors of Heaven in Elect-of-Places (Luxor)," it being the duty of the chief officiating priest to open the doors of the shrine or sanctuary at an early stage of the temple liturgy.

Every temple possessed its sacred pool containing the water used for purificatory purposes, and it is to be noted that this pool, for reasons that have been fully set forth above, seems always to have been associated with the sun-god.

Again, every temple down to the latest times possessed its vestry or House of the Morning, an adjunct, as has already been pointed out, of the ancient Heliopolitan sun-temple.

One of the clearest proofs of the complete solarisation of institutional religion in Egypt is to be found in the organisation of the priesthood, which at every temple was divided into four "watches," or, as the classical writers designated them, phylæ. These "watches" bear the names of the four quarters of a ship—the bow-, stern-, starboard-, and larboard-watch, names which mythological texts assign to the four watches into which the crew of the sun-god's ship was divided. It was evidently the Heliopolitan priests who were first divided into four watches bearing these names, for, as already stated, the sun-god was supposed to traverse the heavens in a ship and his priests may well have been regarded as his crew.

The liturgy itself consisted largely of a series of toilet-episodes, and thus closely resembled the ceremonial toilet of the Pharaoh in the House of the Morning, a resemblance due to the fact that both imitated the same performance, the supposed daily matutinal ablutions of the sun-god, the cultus-image of the divinity (originally the sun-god) being washed or sprinkled with water every day at dawn, as the god himself was believed to be. That the other toilet episodes in the temple liturgy—robing, anointing, crowning, etc.—were like those performed for the king, was due to the fact that the sun-god, for whom the rite was instituted, was himself regarded as a king—the divine prototype of all Heliopolitan kings. The chief officiant at the liturgy was supposed to be the Pharaoh, but it was of course impossible for the supreme head of the highly organised Egyptian state of historic times to function daily as high-priest, even in the temple at the capital, let alone in the countless temples scattered over the length and breadth of the land. His place was therefore taken by a deputy, the local high-priest, or some other member of the higher grade of the priesthood. In addition to the chief officiant a number of assistant priests took part in all the ceremonies, as certain representations clearly show.

The liturgy falls into three main divisions: (1) A series of pre-toilet episodes, among which were included the unbolting and opening of the sanctuary or naos doors, the sweeping of the sanctuary floor with a cloth or besom, preliminary fumigations with incense, the prostration of the celebrant, the chanting of the praises of the god, and the removal of the image from the shrine. (2) The lustral washing of the image, followed by a long series of other toilet performances. (3) The liturgy terminated with the presentation of a meal to the god, a lengthy and highly ceremonious proceeding. When the food- and drink-offerings had all been laid in order before the image—the heaped-up food offerings surmounted with bouquets of flowers and the wine-jars wreathed with garlands—the officiant extended his right arm and, bending his hand upwards in the prescribed manner, pronounced a formula beginning with the words "An offering which the king gives." The recitation of this formula was preceded by the burning of incense and the pouring out of a libation. The priest having next recited the formula of "Summoning the divinity to his repast," performed the act of consecration, by which each item of food and drink was finally made over to the divine banqueter. This act consisted in the king, or his deputy the priest, standing before what was to be offered, and four times stretching out over it or towards it a ceremonial baton called the *kherp*-baton, which he grasped in his right hand.

The last act of the officiant before he left the sanctuary was to remove all traces of his own and his assistants' footprints. This he did by sweeping the floor once more with a cloth or besom. The sanctuary door was then closed and bolted and a clay seal affixed to the bolts.

Before bringing this preliminary article to an end, it should be pointed out that music, vocal and instrumental, was a great feature of Egyptian worship—a much greater feature than may have appeared from what has already been said in connexion with the musician-priestesses. These priestesses, it would seem, headed by the god's earthly wife, the high-priestess, rattled their sistra, beat single-membrane drums, and chanted hymns in the divinity's praise, all the time that the chief officiant and his assistant priests were executing the various ritual acts, while male musicians also

bore their part in the proceedings, singing, and playing on flutes and stringed instruments.

The following and concluding article will deal with the monotheistic Aton-religion instituted by Ōkhnatōn, and so enthusiastically practised and propagated by him at his capital, El-Amarna, in Middle Egypt.

The Photosynthesis of Plant Products.[1]

By Prof. I. M. HEILBRON.

DESPITE the enormous strides that have been made by chemists during the last decades in the elucidation of many classes of plant products and the actual synthesis of individual members, the methods hitherto employed in the laboratory are so essentially different from those carried out by the plant that the synthetic processes of the living organism have come almost to be regarded as something fundamentally apart from those of the laboratory. The investigations on photosynthesis now being carried out in Liverpool by Prof. Baly and myself, although as yet of a quite preliminary nature, have, in my opinion, already shown that such a conclusion is entirely unwarranted and that the key to the problem of plant syntheses is to be found in the study of the energy transformations involved in the primary reaction wherein the plant brings about the fixation of atmospheric carbon dioxide. Apart from the purely academic interest of the subject, the problem of photosynthesis demands the attention of the community as a whole, for, with the elucidation of the reactions involved, the economic aspect of the question must inevitably become more prominent, and practical results of the greatest value to mankind may conceivably accrue.

The work of the earlier investigators on the subject has led to the formulation of certain definite conclusions. Thus, it has been proved beyond question that photosynthesis takes place in the green leaf of the plant and that, under natural conditions, assimilation apparently consists in the absorption of carbon dioxide by means of the chlorophyll contained in the chloroplasts and its deoxidation and condensation therein, in the presence of water and sunlight, to sugars. It is obvious that, in order to obtain any satisfactory explanation of the rôle played by the chlorophyll, its constitution, and above all its reactions, must be known. The first advance in this direction is due to von Baeyer,[2] who suggested that the initial product of assimilation was formaldehyde, which then further condensed to form carbohydrates. This hypothesis was rapidly put to the test in two directions. Innumerable attempts have been made to prove the presence of formaldehyde in the green leaf itself, but in every case where this appeared to be established its formation could as readily be explained as being derived from sources other than assimilation. As regards the production of formaldehyde from carbon dioxide *in vitro*, this has actually been carried out in numerous ways,[3] none of which, however, are directly comparable with the conditions existing in the plant itself. The most detailed work in this connexion is that of Moore and Webster,[4] who showed that, under the action of light, formaldehyde was readily produced in solutions of carbonic acid containing colloidal uranium hydroxide or ferric hydroxide. As a result of these experiments, Moore concluded that, although chlorophyll had come to be universally regarded as the fundamental agent for photosynthesis, the evidence was purely inferential, and it was more probable that the synthesis of formaldehyde in the presence of sunlight was actually due to the inorganic iron present in the colourless portion of the chloroplast.

Recent research shows this hypothesis to be incorrect. Iron is undoubtedly essential to plant life, just as it is to animal life, and its function seems to be closely associated with chlorophyll formation. Leaves starved of iron suffer from chlorosis but, in these, photosynthesis does not take place, and there can be little doubt that the real catalyst for the assimilation reaction is chlorophyll. Our knowledge of the constitution of this interesting and highly complex pigment is mainly due to the work of Willstätter and his collaborators,[5] who have established the fact that the following four pigments are invariably present in the green leaves of all land plants: Chlorophyll A, $C_{55}H_{72}O_5N_4Mg$, chlorophyll B, $C_{55}H_{70}O_6N_4Mg$, carotin, $C_{40}H_{56}$, and xanthophyll, $C_{40}H_{56}O_2$. From an exhaustive study of the assimilation of carbon dioxide by the green leaf, Willstätter[6] has been able to arrive at certain very important generalisations. He has found that in all cases the oxygen evolved is absolutely equivalent to the carbon dioxide absorbed, which definitely proves that formaldehyde must be the first product, since the primary formation of such other substances as have from time to time been suggested would necessitate a volume ratio greater than 1 : 1. Further, from the results of experiments carried out both in the leaf and *in vitro*, he has been able to show that, although chlorophyll is inactive to dry carbon dioxide, it is nevertheless capable of combining with carbonic acid to form a labile addition compound. He concludes that this latter, by the absorption of light energy, is rearranged into a formaldehyde peroxide complex from which, by means of enzyme action, formaldehyde is liberated, oxygen evolved, and chlorophyll regenerated.

[6] Willstätter und Stoll, "Untersuchungen über die Assimilation der Kohlensäure," Berlin, 1919.

This work still leaves much unexplained and in no way helps to disentangle the paradox that whereas, on one hand, formaldehyde must actually be produced, it nevertheless does not exist in the leaf. Nor does it afford an explanation of the rapid synthesis of either the disaccharides, such as cane-sugar, or of storage starch. Again, it is curious that, if the reactions are actually those specified by Willstätter, Nature should, apparently by caprice, invariably ensure the presence of the two chlorophyll components and also the carotinoid pigments, when one chlorophyll individual would by itself be sufficient. It would seem more probable that the four pigments are present because each has an absolutely definite rôle to play in the mechanism of assimilation. This suggestion is strongly supported by a consideration of the striking oxygen values existing between the two pigment classes, these being in strict agreement with the amount of oxygen liberated in the photosynthetic operation.

Returning now to the consideration of the primary synthesis wherein carbonic acid is deoxidised to formaldehyde, this reaction is a highly endothermic one, impossible to realise under the conditions commonly employed in the laboratory. On the other hand, carbonic acid is able to absorb light of very short wave-length ($\lambda = 200\ \mu\mu$), and, if exposed to light of this frequency, the formation of formaldehyde, without the agency of any catalyst, can readily be demonstrated under these purely photochemical conditions. Moreover, in the presence of a suitable basic coloured substance, such as malachite green, with which the carbonic acid can combine loosely, the formation of formaldehyde can be demonstrated in visible light, the malachite green acting as a photocatalyst for the reaction.[7]

Carbohydrate Production.

The formation of sugars on exposure of aqueous solutions of formaldehyde to ultra-violet light was demonstrated by Moore and Webster.[8] These observations have been fully confirmed, and it has been found that the wave-length of light which brings about this reaction ($\lambda = 290\ \mu\mu$) is photochemically distinct from that required for the synthesis of formaldehyde itself. In our earlier experiments in Liverpool, it was considered that the photosynthetic formation of carbohydrates had to take place in two distinct stages, but, as will be explained below, later experiments have shown that this interpretation was incorrect, the actual process being simpler. The formaldehyde molecule, when first produced by photosynthesis from carbon dioxide, exists in a highly reactive phase, identical with that obtained when ordinary formaldehyde is photochemically activated. This type of formaldehyde we have designated "activated formaldehyde," and it is this which must be photocatalytically produced through the agency of the chlorophyll, and immediately condenses to sugars, for, as is well known, ordinary formaldehyde has no such property. It follows from this that the formaldehyde detected in the carbonic acid experiments cannot have been a direct product of photosynthesis, but must have resulted from a subsequent decomposition of photosynthesised sugar. That carbohydrates readily yield formaldehyde under the influence of short wave-length light has been proved experimentally, and thus the detection of formaldehyde in any photochemical operation may be regarded as sure evidence of photosynthesis.

The investigation into the nature of the sugars formed by the photochemical activation of formaldehyde is still being carried out, but we have been able to prove conclusively that the condensation leads to the production of hexose sugars alone. This fact affords a ready explanation of the formation of disaccharides and starches, for the freshly photosynthesised hexose molecule must exist in a highly reactive phase, and consequently further condensations will inevitably take place.

Nitrogen Assimilation.

The problem as to the origin of the many classes of nitrogen compounds occurring in the vegetable kingdom is one fully equal in importance to that of the formation of carbohydrates, but although many have speculated on their possible synthesis, little definite evidence has hitherto been adduced to account for their production. The questions which have to be considered in this connexion are, first, under what conditions and in what state does the nitrogen enter the plant, and secondly, is the fixation process a photosynthetic reaction? With regard to the manner in which nitrogen is supplied, the general method would appear to be that it passes into the roots in the form of nitrates, or possibly ammonium salts, present in the soil. In addition to the introduction of nitrogen in this manner, Moore [9] has found that in the case of unicellular algæ, providing abundant carbon dioxide is present, elemental nitrogen from the atmosphere can be absorbed and directly utilised. This discovery, which is of quite exceptional interest and fully corroborates Jamieson's [10] earlier investigations, is still further supported by the recent observation of Lipman and Taylor,[11] who claim to have proved that ordinary wheat is able to assimilate up to 20 per cent. of its total nitrogen content in the form of free nitrogen.

It was noted by Schimper that nitrites are invariably present in the green leaf when kept in the dark, but that they rapidly disappear on exposure to light, and the deduction may thus be drawn that these are the active substances employed in the nitrogen fixation. The direct assimilation of atmospheric nitrogen in no way invalidates this conclusion, for there can be little doubt that the free nitrogen will readily react with the nascent oxygen formed during the photolysis of the carbon dioxide to yield oxides of nitrogen.

With these facts in mind, exhaustive experiments are now being carried out in Liverpool on the interaction of nitrates with activated formaldehyde. It has been found that under all conditions the primary reaction product is formhydroxamic acid,[12] $\begin{matrix} H \\ HO \end{matrix}\!\!>\!C{=}NOH$, a substance which had previously been obtained by Baudisch [13] in his pioneer work in this field. The formation of formhydroxamic acid takes place only in the presence of activated formaldehyde, no trace of it being found

when solutions of ordinary formaldehyde and potassium nitrate are allowed to remain in the dark. Now, as this acid is also produced on passing carbon dioxide through aqueous solutions of either potassium nitrate or potassium nitrite exposed to ultra-violet light, the requisite proof is furnished of the statement that the freshly synthesised formaldehyde must be beyond doubt activated formaldehyde. These experiments have led us to the conclusion that formhydroxamic acid marks the initial stage in the phytosynthesis of nitrogen compounds. This view is further substantiated by the fact that, on exposure to ultra-violet light, formhydroxamic acid rapidly reacts with activated formaldehyde to form various other products, many of a complex nature, whereas in the absence of light no such change occurs.

In the course of these experiments, other facts of great importance have been noted. It has been found that by employing excess of nitrite no reducing sugars whatsoever are formed, but that if the activated formaldehyde is in excess of that utilised by the nitrite, the presence of reducing sugars can be readily detected. These experiments prove that the synthesis of nitrogen compounds by the interaction of nitrites with activated formaldehyde takes precedence over the condensation of the latter to carbohydrates. In the plant, however, as the amount of nitrogen actually fixed is small in comparison with the total carbon assimilated, both carbohydrate and protein formation take place simultaneously.

As regards the type of substances which have been classified up to the present, conclusive proof of the formation of α-amino acids has been obtained, and thus a definite intermediate stage in protein production has been reached. At least four distinct types of α-amino acids have so far been isolated in the form of their copper salts, and it is certain that at least one of these is a complex acid, possibly analogous to histidine.

In addition to the synthesis of amino acids, nitrogen bases, such as methylamine, pyridine and piperidine, have been isolated. Substances of alkaloidal character are also formed in the reaction, but as yet we have been unable to separate any one alkaloid in sufficient quantity for detailed investigation.

Another line of attack, at present in active progress, is the study of the action of ammonia on photochemically activated formaldehyde. Here again it has been ascertained that, whether one starts from carbon dioxide and ammonia or from ordinary formaldehyde and ammonia, identical products are obtained. Moreover, although under normal conditions interaction only occurs under the influence of light of very short wavelength, by employing ammoniacal copper solutions the reaction can be photocatalysed to take place in visible light. In all cases the presence of methylamine, pyridine or piperidine, can again be recognised after comparatively short exposure to light, and by extending the period of illumination to several days the presence of alkaloids can also be experimentally confirmed.

In this case it has been possible to isolate an individual alkaloid in sufficient quantity to enable numerous qualitative and physiological tests to be carried out. Despite the difficulties of identification of these substances, the experimental evidence obtained would seem definitely to indicate that this photosynthetic alkaloid is coniine.[14]

In conclusion, I would direct attention to some general deductions naturally arising from the work in hand. According to the views now put forward, it necessarily follows that, both in the case of the photosynthesis of carbohydrates and also in that of the phytosynthesis of nitrogen products, the whole centre of activity must be contained in the green leaf itself. As to the manner in which translocation from this point to other portions of the plant is brought about, it may be suggested that, as the synthesis of active hexoses takes place concurrently with the production of nitrogen compounds, the conditions are especially favourable for glucoside formation. In this way a method would be found for the easy removal of insoluble materials from the leaf.

Finally, I would emphasise the point that in regard to the work being carried out by Prof. Baly and myself, our only claim is that we consider it by no means impossible to reproduce in the laboratory processes strictly analogous and directly comparable with those taking place in the plant. The chemistry of photosynthesis is new and strange, and as such will undoubtedly be viewed with a certain degree of scepticism, for the inherent conservative spirit among even scientific investigators tends to react against any new order of things. Photosynthesis is in the main the chemistry of one single substance—formaldehyde. The whole process is dependent on energy supplied from the sun and made available through the wonderful activity of the pigment chlorophyll.

Obituary.

LORD CARNARVON.

WE much regret to record that Lord Carnarvon died at Cairo on April 5, from the effects of pneumonia, supervening on erysipelas and blood-poisoning, the result of a bite on the cheek by an insect, presumably a mosquito.

Lord Carnarvon was born on June 26, 1866, and was the son of the fourth Earl, whom he succeeded in 1890. He was educated at Eton and Trinity, Cambridge. He travelled extensively, won a reputation as a big-game shot, and was interested in the Turf. He was a great connoisseur and collector of illuminated books, manuscripts, and medals, as well as of antiquities of fine workmanship and small size. Of the last-named he had a remarkable and, in some respects, a unique collection. It is, however, in connexion with the study of the history and antiquities of Egypt that Lord Carnarvon's name will be handed down to posterity. In 1906 he, in association with Mr. Howard Carter, formerly inspector under the Egyptian Antiquities Department, began excavations, chiefly on the north side of the Assassif Valley near Der el Bahari, which resulted in the discovery, among other finds, of the tomb of the "King's Son" of Dynasty XVIII. in 1908 and, in 1910, of a rich tomb of Dynasty XII. The results of these early excavations were embodied in Lord Carnarvon's "Five Years' Excavations in Thebes," which appeared in 1912.

After the War, Lord Carnarvon began excavations in the Valley of the Kings, a site which had rewarded

the excavations of Mr. Theodore M. Davies with some remarkable finds. No striking results were obtained until November 5 last, when Mr. Carter discovered the tomb of King Tutankhamen—a discovery unique in the annals of archæology. The interest of the objects taken from the tomb, remarkable both in their number and character, grew from day to day, and culminated on February 17, when the opening of the inner chamber revealed the shrines in which it is expected that the body of the king will be found. Work was then closed for the season.

It adds a note of tragedy to Lord Carnarvon's death that he will not be present when the opening of the innermost shrine crowns his labours, but his name will always be honoured as one who added a vast store to our knowledge of the civilisation of Ancient Egypt.

Dr. C. I. Forsyth Major, F.R.S.

Dr. Charles Immanuel Forsyth Major, who died at Munich on March 25, aged seventy-nine, was born in Glasgow, of Scottish parents, but removed when an infant to Constantinople, and lived for most of his life abroad. He was educated in Switzerland, Germany, and Italy. Graduated Doctor of Medicine in Basle in 1868, and began his career as a medical practitioner in Florence.

Dr. Major was, however, always interested in natural history, and his association with Rütimeyer in Basle led him to become an enthusiastic student of fossil mammals. While occupied with his professional duties in Florence, he took every opportunity of collecting and examining the mammalian remains found in the superficial deposits in the valley of the Arno, and from 1872 onwards he published in Italy a series of small papers on these remains, describing and discussing them in a more exhaustive manner than had previously been attempted. He summarised his results in the Quarterly Journal of the Geological Society of London in 1884, pointing out that the later Pliocene mammals were all distinguishable from those of the early Pleistocene when fossils were studied in detail. At the same time he published valuable memoirs on the dentition of rodents from the Bohnerz of Switzerland and South Germany (*Palæontographica*, xxii., 1873), and on the dentition of the early true horses (*Abhandl. Schweiz. Paläont. Ges.*, 1877–80).

About 1886 Dr. Major abandoned his medical practice, and began to devote himself entirely to scientific research. With the help and encouragement of his Swiss friend, M. W. Barbey, he made a thorough exploration of the Pliocene accumulation of mammalian bones in the island of Samos, and brought back a great collection, of which part was presented by M. Barbey to the Collège Gaillard at Lausanne, and the other part was purchased by the British Museum. In 1889 Dr. Major made another important collection of mammalian remains from a Pliocene torrent-deposit at Olivola in the Carrara mountains in Italy, and this was also purchased by the British Museum. Dr. Major followed his collections to the British Museum, and was temporarily employed there in cataloguing the fossil mammals until 1909. While thus occupied he published a valuable series of papers in London. He also arranged to prepare a Catalogue of Fossil Rodentia for the British Museum, and a large monograph of the Samos Mammalia, which unfortunately were never produced.

In 1893 Dr. Major contributed his important memoir on the skull of a giant lemur, Megaladapis, from a cavern in Madagascar, to the Philosophical Transactions of the Royal Society, and the novelty of this discovery led him to plan an exploration of the caverns and marshes of Madagascar. With the aid of a government grant from the Royal Society, he visited Madagascar in 1894–95, and brought back an important collection of fossil mammals and birds, which is also now in the British Museum. On these fossils he wrote several descriptive papers.

In his later years, however, Dr. Major found increasing difficulty and diffidence in preparing his results for publication, although his researches were pursued with accustomed diligence. Much of his valuable work on rodents and on the relationship between the fossil Samotherium, which he discovered in Samos, and the existing okapi of the Congo Forest, is thus unfortunately lost to science. Dr. Major was elected a fellow of the Royal Society in 1908, and about the same time was awarded a small Civil List pension. He then returned to the Mediterranean region which had interested him for so many years, and spent most of the remainder of his life in Corsica. He still continued to collect and study mammalian remains, chiefly from the caverns and rock-fissures of Corsica, but he now ceased to do more than make manuscript notes.

A. S. W.

Mr. E. W. Vredenburg.

Geology has lost a cultured worker by the death of Ernest Watson Vredenburg, who passed away on March 12, at the age of fifty-three. His death was probably hastened by the constant and now painfully verified foreboding that he might never be able to finish the great task which he had undertaken of revising the Tertiary palæontology of the Indian region. We have had occasion at times to notice some of the numerous instalments which he has published during the past few years in the Records of the Geological Survey of India; they and other papers now in the press were intended to prepare the way for a comprehensive monograph which he hoped would justify his reason for differing from his colleagues on some questions of stratigraphical correlation; but the burden was too great for that hyper-sensitive, artistic, and retiring nature which tended to keep him apart from his colleagues, who nevertheless appreciated his deep learning, unrelenting industry, and tenacious adherence to independent views.

Mr. Vredenburg, who was half French in race and wholly so in upbringing, graduated at Paris in Science and Letters before entering the Royal College of Science and School of Mines, where he took a double associateship, in geology and mining, before joining the Geological Survey of India in 1895. He spent the first part of his official work on the relatively uninteresting unfossiliferous rocks of Central India, and did not get an opportunity of discovering his main bent till his transfer to Baluchistan, the geological features of which he revised and summarised in 1910. There and in the adjoining regions of Sind he became deeply interested in the stratigraphy and palæontology of the

Lower Tertiary system, extending his work afterwards to the younger beds in the Burma oil-fields.

South Kensington students will remember him as a brilliant pianist who would have had a distinguished position in the musical world if he had not concentrated on the palæontology of India. During his early days in India he showed a tendency to become engrossed in archæological interests until palæontology claimed him first as a devotee and finally as a victim.

Count Fernand de Montessus de Ballore.

THE small band of seismologists has suffered a serious loss through the death of M. de Montessus de Ballore. Born in 1851, he was trained at the École Polytechnique, where he was a fellow-student of Marshal Foch. In 1881 he was sent as chief of a military mission to San Salvador. There he became interested in the frequent earthquakes of the Central American republics, and he continued his seismological studies on his return to Paris as Directeur des Études at the École Polytechnique. In 1907 he was appointed director of the earthquake-service in Chile, a service which, through his efforts, became one of the first rank.

De Montessus will be chiefly remembered and valued for his studies on the distribution of earthquakes. His great work on "Géographie Séismologique," which occupied his leisure for twenty-four years, was published in 1906. Few men could be so well qualified as he for an undertaking so vast, for he had a good knowledge of six foreign languages. Having collected records of nearly 160,000 earthquakes, he showed that seismic regions follow the principal lines of relief, that, in a group of unstable regions, the most unstable are those of the greatest relief, and that more than 90 per cent. of the earthquakes occurred along two narrow zones occupying great circles of the earth, which he called the Mediterranean circle and the circum-Pacific circle. In 1907 his second work, "La Science Séismologique," appeared and at once took its place as an authoritative treatise.

Besides these two volumes and a small popular book published in 1911, de Montessus was the author of many memoirs. One of the latest was a bibliography of seismology containing the titles of more than 9000 books and papers. In the preparation of these works, he had collected a library, perhaps the most extensive of the kind in existence. This was bought a few years ago by the late President J. C. Branner, and was presented by him to the University of California. C. D.

Prof. M. Abraham.

THE issue of the *Physikalische Zeitschrift* for February 1 contains an obituary notice of Prof. Max Abraham by Profs. M. Born and M. v. Laue. He was born at Danzig in 1875 and studied under Planck at Berlin. After graduating he became Planck's assistant, and in 1900 privatdozent at Göttingen. For a short time in 1905 he acted as professor at the University of Illinois, and, after his return to Göttingen, was in 1909 appointed professor of theoretical physics at Milan. The War ended this, and he held temporary posts till last year, when he was appointed professor of theoretical mechanics at Aix-la-Chapelle. Illness prevented him commencing duties there, and he died of tumour on the brain on November 16, 1922. He was well known in this country for his book "Theorie der Elektrizität," for his articles on vectors and on electromagnetic waves in the "Mathematische Encyklopädie," and for his papers on the dynamics of electrons, all giving evidence of a clear and logical mind.

WE regret to learn from Australia of the death, at the end of January, of Dr. J. L. Glasson, at the age of thirty-four years. Dr. Glasson was a student of the University of Adelaide, where he worked under Sir William Bragg, and from that University he received his doctor's degree. He succeeded in winning a travelling research scholarship of the Exhibition of 1851, and with it came to this country. He entered Gonville and Caius College, Cambridge, in 1909 as an advanced student, and, going to the Cavendish Laboratory, did valuable research work under Sir J. J. Thomson. In 1912 he was appointed lecturer in physics in the University of Tasmania, Hobart, and while there he did valuable work for the Electrolytic Zinc Co. and for the Tasmanian Carbide Co. This post he resigned in 1919, returning to Cambridge for research for a couple of years, after which he accepted an appointment as lecturer in physics in the University of Melbourne, which he held at the time of his death.

THE sudden death from angina pectoris on March 15 of Mr. G. E. Bullen, Curator of the Herts County Museum at St. Albans, is announced. Among the smaller museums in the country there can be few which have been raised to such a pitch of excellence, and this has been due entirely to the whole-hearted devotion and enthusiasm of Mr. Bullen during the past twenty years. A considerable extension and rearrangement of the collections has recently been completed, and, especially on the archæological side, the museum is now a model of what a local museum should be, the clear demonstrative labelling of the exhibits being a special feature. Mr. Bullen's work had been for some time carried on in defiance of indifferent health, and his death at the early age of forty is a great loss.

THE *Chemiker Zeitung* of March 17 announces the death in the beginning of March of Prof. Robert Scheibe, formerly professor in the Academy of Mines, Berlin, and later active in South-west Africa and Bolivia. In the issue of March 15 the death on March 10 of Prof. Ernst Salkowski, since 1880 director of the chemical side of the Berlin Pathological Institute, is announced. Prof. Salkowski was born on October 11, 1844, in Königsberg, and at first worked with Virchow. His researches covered a wide field in physiological chemistry.

WE regret to announce the following deaths:

Dr. H. H. Stoek, professor of mining engineering in the University of Illinois since 1909, on March 1, aged fifty-seven.

Dr. John Venn, F.R.S., president of Gonville and Caius College, Cambridge, and for many years lecturer in logic and moral philosophy in the University, on April 4, aged eighty-eight.

Mr. S. H. Wells, director-general of the Egyptian Department of Technical, Industrial, and Commercial Education since 1907, on March 28, aged fifty-seven.

Current Topics and Events.

With this issue appears the first of a series of supplements which it is proposed to publish from time to time dealing descriptively with subjects of wide scientific interest. The present supplement is devoted to a discourse delivered at the Royal Institution on March 2 by Dr. G. C. Simpson, director of the Meteorological Office, and it provides in a convenient form a synopsis of existing knowledge of common meteorological phenomena. The method of dealing with the subject is characteristic of the present-day physicist, and it is essentially interesting. Saturation and relative humidities are somewhat fully described, and this is followed by a discussion of condensation at temperatures above the freezing point. It is of interest to note that the number of nuclei present in the air varies from a minimum of about 100 per c.c. to 100,000 or 150,000 per c.c. at times in cities such as London and Paris. Condensation nuclei are formed in various ways, one being the household fires and factory chimneys which produce large quantities of nucleus-forming material, chiefly sulphurous oxide. In England something like 5000 tons of sulphur are burnt each day in coal fires, giving enough sulphur products to pollute the atmosphere of the whole of Great Britain. Haze and mist, though so much alike in appearance, appear to be fundamentally different, haze owing its origin to foreign matter and a small amount of water, while mist is due to an actual precipitation of water from vapour to liquid. On the other hand, there appears to be no fundamental difference between mist and fog, fog is generally only a dense mist. Above the fog temperature inversion prevents all upward motion of the air and the smoke made by large towns is kept fairly stationary and within a few hundred feet of the ground. Clouds, rain, thunderstorms, hail, snow, and other aspects of weather are so often topics of conversation that Dr. Simpson's authoritative discourse upon them will be welcomed by all scientific readers.

The nomination of Sir David Bruce as president of the British Association for the meeting in Toronto next year is a well-deserved honour which will be gratifying to the many friends and admirers of this distinguished scientific investigator. Sir David belongs to the Royal Army Medical Corps, and early in his career made a name for himself by cultivating the *Micrococcus melitensis* and establishing its causative relationship to Malta fever by reproducing the disease in monkeys. Later, in 1904, he was the leader of the Royal Society's Malta Fever Commission, which made the important discovery that fifty per cent. of the goats in Malta were infected and ten per cent. of them excreted the micrococcus in their milk. Within a year of prophylactic measures based on this fact being put in force, the cases at Malta fell to one-tenth of the former numbers, and since that time the Navy has been practically rid of one of the main causes of sickness in its personnel. Of still greater interest and importance are Sir David's patient and well-thought-out researches on the greatest obstacle to the civilisation of tropical Africa, tsetse-fly disease of animals and man. His demonstration of the *Trypanosoma Brucei* as the cause of the fatal tsetse-fly disease of cattle and horses in 1894 paved the way for his demonstration in 1903 that "sleeping sickness is, in short, a human tsetse-fly disease," by a wonderfully well conceived and worked-out experiment carried out as leader of a series of Royal Society Commissions working in Africa over a number of years. The etiology of two of the most important tropical fevers was thus elucidated by his investigations, with widespread results. Sir David is characterised by the thoroughness of his work and the intuition he has always brought to bear on every problem he has tackled. He is very fortunate in his helpmeet, Lady Bruce, who has shared in both the hardships and the scientific work of his many African expeditions.

Fifty years ago, on April 18, 1873, Justus von Liebig died at Munich at seventy years of age. In 1824, at the early age of twenty-one, he began his career as professor of chemistry at Giessen and he devoted the first twenty years of his academic work to researches in the field of organic chemistry and in developing and perfecting practical laboratory instruction. The results of these labours quickly met with general recognition, and on his first visit to England Liebig was referred to by Faraday, at the meeting of the British Association at Liverpool in 1837, as one of the greatest of living chemists. Great difficulties had to be overcome by Liebig when he began to extend his theoretical and practical work to biological problems. In 1840 he published "Organic Chemistry as applied to Agriculture and Physiology," and in 1842 "Animal Chemistry, or Organic Chemistry as applied to Physiology and Pathology." The doctrines of the nutrition of plants and animals contained in these epoch-making works were at first rejected by chemists, physiologists, and agriculturists, but most of them were established in the course of the following years. Liebig's view that plants build up their organic parts exclusively from the carbon dioxide of the air and the water contained in the atmosphere and the soil, and that in intensive agriculture the mineral substances, especially potash, phosphoric acid salts, and nitrogen compounds, must be supplied to the soil in the form of artificial fertilisers, in addition to natural manure, was first accepted in England. After Liebig had modified his original opinion that the artificial fertilisers must be fairly insoluble in order not to be washed away by the rain, having recognised the extent to which the soil is capable of absorbing these substances, his doctrine of artificial fertilisation was generally accepted and forms the foundation of modern agriculture. In 1864 and 1865 Liebig wrote, at the request of the Lord Mayor of London, important papers on the utilisation of the sewage of London. Other widely-known publications are those on meat extracts,

baking methods, soup for infants, silver mirrors, etc. Liebig gave a popular exposition of his views in his "Familiar Letters on Chemistry," a work from which many students of science have derived interest and inspiration.

THE season's excavations at Ur of the joint expedition of the British Museum and the University of Pennsylvania closed early in March. The chief results were described by Mr. C. Leonard Woolley in a lecture, reported in the *Times* of April 2, which he delivered at Bagdad before leaving for England. The excavations were made in a walled enclosure, resembling a citadel, within the walls of the city, in which the most prominent building was a *ziggurat* of four stories, the tower of the Temple of Nanna, the Moon god, completed about 2250 B.C., and coated with blue glazed bricks by Nabonidus about 550 B.C. One of the most interesting finds was a headless diorite statue of Eannatum, King of Lagash about 2900 B.C., which may have been a trophy of war. From its earliest beginnings, possibly in 3600 B.C., until it was altered by Nebuchadnezzar in about 600 B.C., the plan of the Temple remained unchanged. The find of a golden statue in a small temple at the foot of the tower indicates that this monarch introduced a change in ritual, to which reference is made in the book of Daniel, and brought the god from the seclusion of the sanctuary out into the open to be an object of public worship and veneration.

A QUESTION agitating workers in several branches of science at the present day rather more intensely than usual is the furnishing of an adequate guide to the growing volume of published work. The lapse of the International Catalogue and the great increase in the costs of production have made the situation acute. It has long been recognised that there is a vast amount of overlap and of wasted effort, and that, if only the various societies and publishing bodies would combine, they could provide a better service at less cost. This was the line followed by Dr. J. R. Schramm, of the National Research Council, Washington, in a recent lecture on the indexing of biological literature (*Science*, November 3, 1922). He held up *Chemical Abstracts* as the example to be followed, and considered that the Federation of American Biological Societies, to which we have previously referred, could produce a similar *Biological Abstracts*, equally complete, at an annual expenditure per member of 6 to 8 dollars. Dr. Schramm, it will be seen, believes that abstracts are what the workers want. Prof. Cockerell, in his comments on Dr. Schramm's proposals (*Science*, January 5, 1923), seems to prefer an analytical index, such as is furnished by the "Zoological Record." We agree with Prof. Cockerell; but, apart from that, the question is: Will a sufficient number of individuals be prepared to pay? The experience of the "Zoological Record" suggests that they certainly will not. This, however, may in part be due to the existence of the many competing, though less complete, abstracts and indexes, and in part to the ignorance and inertia of the workers. If, not only the American societies, but also the biological societies of the whole world, would federate for this purpose, so that the proposed *Record* or *Abstracts* were virtually the only one in existence, and were thus inevitably brought before each individual worker, then success would be assured. But that "if" implies the suppression of vested interests and of the nationalism which hampered the International Catalogue.

THE theory of the tides is a very strong source of attraction for a certain group of unscientific speculators. One of the latest of these to put his ideas into print is Mr. Evan McLennan, of Oregon, from whom we have received a pamphlet entitled "Nature Notes, Critical and Constructive." After betraying a complete misunderstanding of the theory of the tide-generating force on the principle of gravitation, he remarks, "It would, quite probably, be regarded as a far greater violation of the principles of science to question the theory of gravitation than to swallow the inconsistency," and "Of the forty federal institutions established by our own Government alone for the purpose of scientific research and the increase and diffusion of knowledge, and of the more than 1500 investigators paid from the public treasury to do this work, there is in all probability not one who could be induced by an outsider to give the slightest attention to any vital criticism of the Newtonian theory of gravitation." We can assure Mr. McLennan that in his own country alone there is a large number of scientific men who would enthusiastically give their attention to any real inconsistency in the accepted theory of gravitation.

THE Corn Sales Act came into force on January 1, so that it is no longer possible for buyer and seller of corn in Great Britain to misunderstand each other as to the particular kind of stone in which a transaction had been conducted. All such transactions must now be in cwts. of 112 lb. The Union of South Africa has, according to the March issue of the *Decimal Educator*, adopted the cwt. of 100 lb., so that the same kind of difficulty is likely to be felt in dealings between South Africa and this country as we have just avoided here with regard to corn. In both cases the Decimal Association advises the use of the 50-kilogram standard, which is approximately 110 lb. In the same way, to overcome the difficulty of the American gallon being only about five-sixths of the British gallon, the Association and the Metric Association of America recommend the introduction of the litre for all trade in liquids. With regard to our coinage, the Decimal Association is concentrating its efforts on the introduction of a high-value penny, of which 10 would go to a shilling, and the withdrawal of the threepenny-piece. In place of the latter a double-penny nickel coin would be issued. It is not proposed that new penny coins should be issued.

THE annual meeting of the Iron and Steel Institute will be held at the Institution of Civil Engineers, Westminster, on Thursday and Friday, May 10 and 11. The Bessemer medal will be presented to Dr. W. H. Maw, and the award of the Andrew Carnegie research scholarship for 1923 will be announced.

Twenty-four papers will be presented during the meeting, and their subjects will be announced in the Diary of Societies in NATURE.

THE May lecture of the Institute of Metals for the present year will be delivered by Dr. W. Rosenhain at 8 o'clock on Wednesday, May 2, at the Institution of Mechanical Engineers. The subject will be "The Inner Structure of Alloys."

THE Hansen prize for distinguished microbiological work has been awarded this year by the committee of Danish trustees to Dr. E. J. Allen, director of the Marine Biological Association's laboratory at Plymouth, for his experimental researches in marine microbiology. It will be remembered that this award, to which we referred in our issue of February 3, p. 156, consists of a gold medal and a sum of 2000 kroner. Dr. Allen has been invited to visit Copenhagen to receive the medal and to deliver a lecture on his work on May 1.

A WELL-PRESERVED rib of the gigantic dinosaur, *Cetiosaurus leedsi*, obtained by the late Mr. Alfred N. Leeds from the Oxford Clay near Peterborough, has just been added to the other remains of the skeleton exhibited in the geological department of the British Museum (Natural History). The rib measures six feet in length, and is remarkable for its slenderness.

THE three lectures of the series on physics in industry arranged by the Institute of Physics last year will be published shortly in the series "Oxford Technical Publications." The fourth lecture of the series, entitled "The Application of Physics to the Ceramic Industry," will be delivered by Dr. J. W. Mellor on Wednesday, May 9, at 5.30 P.M., at the Institution of Electrical Engineers. Other lectures will be delivered later by Prof. C. H. Desch on "The Physicist in Metallurgy," and by Dr. A. E. Oxley on "The Physicist in the Textile Industries."

As no Bill providing for a period of Summer Time was passed by the French Chamber of Deputies before adjourning for the holidays, the French Government has decided not to define such a period this year, but merely to take particular measures in regard to holiday and health resorts.

THE seventy-sixth annual meeting of the Palæontographical Society was held on March 31 in the Geological Society's rooms, Burlington House, Mr. E. T. Newton, president, in the chair. The annual report of the council referred to the reduction in the size of the society's annual volume owing to increased costs and smaller membership, but announced the early beginning of new monographs of Malacostracous Crustacea, by Mr. Henry Woods, and of Gault Ammonites, by Dr. L. F. Spath. Contributions had been received towards the cost of plates from the University of Bristol and from Mr. F. W. Harmer. Messrs. A. J. Bull, E. Heron-Allen, H. B. Milner, and A. Wrigley were elected new members of council. Mr. E. T. Newton was re-elected president, and Mr. Robert S. Herries and Dr. A. Smith Woodward were re-elected treasurer and secretary respectively.

A NOTE on cleaner air for London appears in the *Meteorological Magazine* for March. The Public Control Committee of the London County Council is considering how far fog in London is the result of atmospheric pollution due to preventable causes, and how far the atmosphere may be improved by the larger use of electricity for power and other purposes. It is also being considered whether further powers are required to deal with the emission of smoke. Detailed reports have been prepared, and these appear to be under discussion by the Council.

A NEW type of pocket magnifier is now included in the optical products of Messrs. Cooke, Troughton and Simms, Ltd., Buckingham Works, York. We have had an opportunity of examining one of these. The lens consists of an achromatic doublet giving a magnification of five with a focal length of 2 in., an aperture of 0·85 in., and a field of view of about 2 in. in diameter. The field is flat and free from distortion and colour, and the definition is good over the whole of it. The lens is fitted in a duralumin mount which can be folded when the magnifier is not in use. Magnifiers of this type are now being supplied with powers of $2\frac{1}{2}$, 5, and 10 respectively.

BEGINNERS in bee-keeping will find some useful information in Leaflet 128, recently revised by the Ministry of Agriculture and Fisheries. Bee-keeping is an occupation eminently suitable for small-holders, cottagers, and others with only a limited space available. The insects are, moreover, active pollinators of fruit blossoms, and consequently have other uses besides the production of honey. Having mastered the contents of this leaflet, we advise the beginner to procure the collected leaflets on bee-keeping (seven in number), which can be obtained from the Ministry, at 10 Whitehall Palce, S.W.1, at the low price of 6*d*., post free.

THE Gifford Emonds prize, value 100*l*., which is awarded every two years for an essay on a subject dealing with ophthalmology and involving original work, and open to any British subject holding a medical qualification, is now open to competition. The subject chosen is "Iridocyclitis." Preference will be given to original work based on any branch of the subject, rather than to compilations of the writings of previous observers. Full particulars of the prize can be obtained from the Secretary Superintendent, Royal London Ophthalmic Hospital, E.C.1. Essays must be sent in not later than December 31, 1924.

MESSRS. H. SOTHERAN AND CO. (43 Piccadilly, W.1) have recently purchased and are offering for sale as a whole the library of books on British ornithology formed by Major W. H. Mullens. It contains about 3000 volumes, and ranges from the "Avium praecipuarum" of William Turner, 1544, to Beebe's recently completed "Monograph on the Pheasants."

THE catalogues issued by the firm of Bernard Quaritch, Ltd., 11 Grafton Street, W.1, are always of interest. The latest one (No. 376) contains up-

wards of 1700 titles (with, in many cases, comments) of books in the following subjects: botany, agriculture, early medicine and surgery, forestry, fruit-culture, gardens and gardening, herbals, and tobacco. As usual, many choice and rare volumes are included.

No. XI. of the "Publications de la Société de Chimie Physique" is a short monograph of 15 pages on isotopes, by M. Maurice de Broglie, which was delivered as a lecture in November 1920. The previous publication was a lecture on Bohr's theory of the constitution of the atom. The monograph is published by Hermann et Cie at the price of 2 francs. Two series of somewhat similar monographs are being issued by the Libraire Scientifique Albert Blanchard. One of these, of which seven parts are announced, consists of groups of two or three lectures on physical subjects. In addition to these a series of foreign scientific monographs is being issued. The third of these, which has recently come to hand, is by Prof. Kossel, and bears the title "Les Forces de Valence et les Spectres de Röntgen." The monograph covers 70 pages, and is issued at a price of 4·50 francs.

THE Society of Glass Technology, which has its headquarters at the University of Sheffield, has issued a useful handbook, a "Directory for the British Glass Industry," price 7*s*. 6*d*. to non-members of the Society. The volume is divided into sections providing lists both alphabetical and classified of glass manufacturers and craftsmen, with particulars in most cases of the class of work produced, and lists of firms supplying material and machinery required in glass making and working. The concluding short sections give useful information concerning industrial associations, trades unions, City Companies, educational institutions, and research associations, and publications dealing with glass technology. It is difficult to understand on what principle the selection of a group of publications, mentioned in the last section, which are referred to as "Periodicals in which articles on glass and ceramics occasionally appear," has been made.

Our Astronomical Column.

A SUPPOSED METEORITE AT QUETTA.—The *Pioneer Mail* for February 23 reports the fall of a supposed meteorite at Quetta on January 25, which, if confirmed, will for the first time establish the power of a meteorite to cause a conflagration. The fragments of the meteorite collected are said to weigh 6 tons, with a volume of 500 cubic feet! Hence the material must be abnormally light for a meteorite. It struck a large stack of closely packed straw 30 feet high, and penetrated it nearly to the ground. The "meteorite" is said to consist of materials like slate-grey igneous rock, volcanic glass, and coke. Possibly the stack was struck by lightning and the fused residue of the straw has been mistaken for a meteorite. The Geological Survey of India will doubtless settle the nature of this phenomenon.

SOLAR ECLIPSE INVESTIGATIONS.—At the meetings of the Australasian Association for the Advancement of Science held at Wellington, N.Z., two papers dealing with observations of the total solar eclipse at Wallal were communicated by Prof. A. D. Ross, who was a member of the Crocker Eclipse Expedition of the Lick Observatory. Shadow bands were observed for two minutes before and for one minute after totality. They altered in appearance, but the most persistent type was indistinct dusky bands about 6 inches wide, at 17-inch intervals, moving in a direction 30° S. of E. at 6 or 7 miles per hour. The bands at times came in groups and developed from a general shimmering effect. Their appearance was inconsistent with a diffraction theory, but suggested irregular refraction due to atmospheric temperature inequalities. The wind was from N.N.W. to N.W. at about 4 miles per hour, and there was a temperature drop of about 8° due to the eclipse. By comparison of six photographic plates exposed to a region surrounding the south celestial pole about mid totality and during twilight the same evening, it was found that the eclipse illumination corresponded to twilight with the sun $7\frac{1}{2}°$ below the horizon. Wellington Anti-screen plates were used. The humidity was about 45 per cent. at the time of totality and about 50 per cent. at twilight, so that it is unlikely that the estimate of brightness was much affected by variation in the transparency of the atmosphere. Determination of the brightness of the corona was attempted with a specially designed integrating photometer, but the measurements of the plates had not been completed.

PLANETARY RADIATION.—No. 460 of the Scientific Papers of the Bureau of Standards, Washington, contains an account of researches made at Flagstaff by W. W. Coblentz on the thermal radiation from planets and stars. A cell of water 1 cm. thick is used to separate the long heat-waves from planets (due either to inherent heat or to warming of the surface by the sun) from the reflected solar radiation. A vacuum thermocouple made of bismuth wire was used to measure the radiations, the instrument being mounted on the 40-inch reflector. Observations on the moon are stated to confirm Very's results, but are not described in detail.

The observations lead to the conclusion that the planetary (long wavelength) radiations, expressed as percentages of the total radiation received from them, are Jupiter (0), Venus (5), Saturn (15), Mars (30), the moon (80). The high figures for the moon and for Mars indicate that rarity of atmosphere increases the warming of the surface; further, the northern hemisphere of Mars, which was in autumn, and more cloudy than the southern hemisphere, indicated a lower planetary radiation. It is hoped to compare the radiation from the orange and dusky regions of Mars, which might give a clue as to the conjectured interpretation of the latter as regions of vegetation.

The zero figure for Jupiter is concluded to be due to the enormously thick atmosphere, which acts as an opaque screen to the radiations from the (supposed) heated interior. The instrument is restricted to wavelengths 7 to 12 μ. Hence nothing can be stated about radiation between 4 and 7 μ, or from 12 to 15 μ.

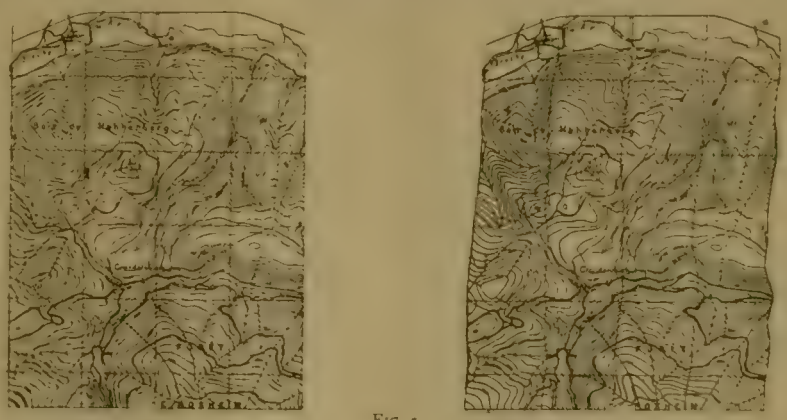
The star temperatures are given as 3000° for type M, 5900° for Capella and sun (type G), and 12,000° for type B, in close accord with previous results.

Research Items.

MIGRATIONS OF THE WAXWING.—The waxwing, *Ampelis garrulus*, is not a rare visitor to our shores. Seldom a winter passes but one or more is observed in eastern parts of Britain, and occasionally its numbers indicate a very considerable immigration. The largest ever witnessed in Scotland occurred in the late autumn of 1921, and is discussed by Dr. J. Ritchie in the *Scottish Naturalist*, September 1922–February 1923. The immediate cause of Scotland's share in this immigration is due in the first place to the lack of food-supply in Norway. The summer of 1921 in that country has been notorious for the lack of wild berries upon which the waxwings feed. Large flocks of the birds congregated in the southern part of Norway, but, finding insufficient food, took advantage of easterly winds accompanied by a rapidly rising barometer to reach our shores. The meteorological phenomena associated with the migration are complex, and Dr. Ritchie promises to deal with them in a future paper.

BOTANICAL SURVEY AND ECOLOGY IN YORKSHIRE.—Under this title a most valuable and comprehensive account of the development of our knowledge of the Yorkshire flora is given by Dr. T. W. Woodhead in the *Naturalist* for March 1923. The first flora of Yorkshire was published at Halifax in 1840 by Henry Baines, and since then the three Ridings have been more intensively dealt with in the three well-known floras, Baker's "North Yorkshire," Arnold Lee's "Flora of West Yorkshire," and Fraser Robinson's "Flora of the East Riding of Yorkshire." Many other valuable systematic works dealing with the Yorkshire flora are described by Dr. Woodhead, who then proceeds to narrate the development of botanical survey and the mapping of plant associations, under the inspiration of the brothers Robert and William G. Smith. Around these men an active band of workers gathered, and in December 1904 the Central Committee for the Survey and Study of British Vegetation was formed at a meeting held at the house of Dr. W. G. Smith in Leeds; in 1913 this Committee was replaced by the British Ecological Society with its wider membership. Two vegetation formations that have been extensively studied in Yorkshire are the woodlands and the moorlands, and Dr. Woodhead briefly traces the development of our knowledge of these characteristic vegetation features, their distribution, development and occasional retrogression. There is an interesting discussion of the significance of the vegetation found in the peat of the Southern Pennines, and the bearing that the studies have upon persistence of the flora from pre-glacial times. Dr. Woodhead's work upon the relation of vegetation survey to the many other activities and interests of a district was well illustrated by the extraordinarily interesting series of maps of the Huddersfield area that were on view in Hull during the British Association meeting, in the exhibition room of the Yorkshire Naturalists' Union. It is therefore natural to find that the presidential address to the Yorkshire Naturalists' Union closes with the expression of a hope that such ecological studies may extend to man, and that the local museum may enshrine the results of an intensive local survey of plant and animal, including human communities.

A NEW PROCESS FOR MAKING STEREOSCOPIC MAPS.—A paper read at a recent meeting of the Paris Academy of Sciences (*Comptes rendus*, January 22) described a new method, due to M. G. Poivilliers, for obtaining stereoscopic maps. The various methods proposed hitherto have been based on the use of two conical perspectives, the production of which involves practical difficulties; in M. Poivilliers's method two cylindrical projections are used, one vertical and the other oblique. Referring to the accompanying illustration (Fig. 1), the projection A is an ordinary contour map; the projection B is obtained from A by shifting the contour lines in the direction east-west by an amount proportional to their altitude above an arbitrarily chosen datum line. The resulting stereoscopic view shows theoretically a slight curvature effect which, however, does not alter the relative relief. In examining with a stereoscope even the above reproductions, the result obtained is very striking. The "falsified" map B was in this case drawn by hand with the aid of a tracing of A, but it is easy to imagine a simple apparatus by means of which this can be done semi-automatically. The contour interval is in this case 20 metres, and corresponds to a horizontal shift of 0·5 mm. It is anticipated that M. Poivilliers's method, on account of its simplicity, will tend to generalise the use of stereoscopic maps, especially for purposes of instruction in topographical surveying. It has also been suggested that the process could be usefully applied to geological maps, by making it possible, for example, to visualise the superposition of successive layers inside the earth.



A—Ordinary contour map.

FIG. 1.

B—Complementary map, with contour lines displaced.

ATMOSPHERIC HUMIDITY IN THE UNITED STATES.—Prof. R. de C. Ward, of Harvard University, is the author of a communication on the above subject in the U.S. *Monthly Weather Review* for November 1922. The communication is admirably illustrated with diagrams; two are given for January, at 8 A.M. and 8 P.M., and two for the corresponding hours in July, showing the relative humidity by lines of equal value over the whole of the United States. The element is a real and definite factor in climate, and especially affects our bodily comfort. The values give the ratio between the amount of moisture in the atmosphere and the amount which could be present without condensation. On the Pacific,

Atlantic, and Gulf coasts the lines show a distinct tendency to be parallel to the sea-coast. The distribution is chiefly controlled by temperature, direction of prevailing winds, distance, and direction of the chief source of moisture supply, and general topography. Charts given with the communication are taken from the 'Atlas of American Agriculture." A belt of uniformly high relative humidity along the coasts averages about 75-80 per cent., and at times exceeds 90 per cent. on the Pacific coast. Inland, in parts, the minima relative humidity during the hot summers fall to 30 per cent., and even 20 per cent. over the districts of most extreme aridity. Absolute humidity, which shows the actual amount of water vapour in the air expressed in decimals of inches, and known as vapour pressure, is also dealt with; two charts are given showing the equal pressure lines over the United States in the months of January and July. Temperature is essentially the chief control of absolute humidity; in mid-summer the amount of moisture in the atmosphere is generally from two to four times as great as in mid-winter.

GEOLOGY AND THE ICE-CAP IN NORTHERN GREENLAND.—The interest of Dr. Lauge Koch's geological mapping in Northern Greenland (NATURE, vol. 110, p. 91) is now increased by his preliminary account of Peary Land. His new map (*Am. Journ. Sci.*, vol. 206, p. 190, 1923) shows the continuation of the Caledonian folding through the north of the region, where moraine-matter from the glaciers descending from the south obscures much of a country in any case difficult for research. The ice-cap extended a good deal farther north at the maximum of the Pleistocene ice-age, but did not cover all the coastland. It may be remarked that in this area we have once more evidence of the potency of snow-domes in promoting widely spread glaciation. It seems unnecessary, if unfashionable, to shift the pole to account for every local centre of ice-radiation. The main result of Lauge Koch's recent work is the discovery of a richly fossiliferous Ordovician series far greater in extent and thickness (870 m.) than he could anticipate when he began his arduous explorations in 1917.

PRODUCTION OF LEAD IN BRITAIN.—In the numbers of *Chemistry and Industry* for March 16 and 23, Prof. H. Louis contributes a most interesting and valuable account of the production of lead in Britain. He begins with a clear account of lead in ancient times. The first definite mention of the production of lead in Britain occurs in Pliny (A.D. 77); a pig of lead has been found in the Mendip Hills bearing the name of the Emperor Claudius (A.D. 49), and in A.D. 64 smelting in Flintshire began. Some pigs of Roman lead are stamped *ex arg.*, *i.e.* desilvered—probably by cupellation. The progress made in the Middle Ages is described in detail by Prof. Louis, whose articles have a wide interest.

SUBSTITUTION IN THE BENZENE NUCLEUS.—In the *Chemical News* of March 16, Messrs. R. Fraser and J. E. Humphries discuss the problem of substitution in the benzene nucleus in the light of the Lewis-Langmuir theory of co-valence. They start from three simple postulates related to the octet stability of an atom or group, and discuss in an interesting manner many known results in organic chemistry. In the chaotic mass of unco-ordinated facts which lies heavy on organic chemistry a ferment is evidently moving; in time the material will no doubt be brought into order, and discussions of the type of that mentioned cannot fail to be of service in this direction.

EARLY HISTORY OF THE GAS PROCESS.—The early history of the manufacture and distribution of towns' gas was briefly outlined by Mr. D. Brownlie in a paper read before the Newcomen Society on March 20. Van Helmont, in 1600, observed that "coal did belch forth a wild spirit or breath." Other early pioneers include Thomas Shirley (1667), Robert Boyle (1691), Stephen Hales (1726), J. Clayton (1739), Bishop Watson (1781), the Earl of Dundonald (1781), and Minckelers (1784). William Murdoch lighted his house at Redruth with coal gas in 1792. At first the gas was burned at the open end of an iron pipe, but the accidental use of an old thimble led to the introduction of a burner in which the gas was lit at a number of jets issuing from a perforated thimble. Messrs. Boulton and Watt's works at Soho, Birmingham, were illuminated by gas in 1802. The plant erected by Murdoch for this purpose differed in little but scale from the horizontal settings and gasometers of to-day. Lebon, in France, worked along much the same lines as Murdoch, and illumined his house with coal gas in 1801. Winsor illumined part of Pall Mall with gas in 1807. Samuel Clegg introduced lime purification in 1806, and invented the first gasmeter in 1815. In the early days gas was distributed through lead or wood pipes. Cast-iron pipes were introduced in 1810, and wrought-iron pipes in 1825. John Grafton, in 1820, introduced the use of fireclay instead of iron for retorts. This permitted the temperature of carbonisation being raised from 1400° F. to 2000° F. Clegg patented retorts for continuous carbonisation in 1815. The first vertical gas retort was patented in 1828 by John Brunton.

PHOTOMETRY.—In his annual address before the Philosophical Society of Washington, the retiring president, Mr. E. C. Crittenden, presented an interesting survey of problems involved in the measurement of light. The address has appeared in the Journal of the Washington Academy of Sciences (vol. 13, No. 5, March 4, 1923). In the introduction Mr. Crittenden recalls several notable advances in photometry, such as the adoption of the international unit of candle-power by all leading countries except the Germanic nations. In view of the uncertainties attending the use of flame standards, this unit is now usually preserved by the aid of calibrated electric incandescent lamps; the process is analogous to that adopted for the international ohm, derived from a mercury standard but maintained by means of wire resistances. However, there is this important distinction, that we have as yet no adequate, accurate, and reproducible primary standard of light. One of the most hopeful lines of investigation is that pursued at the U.S. Bureau of Standards, where experiments on a black body maintained at a definite temperature have been made; the black body takes the form of a carbon-tube electric furnace matched in colour by comparison with certain standard incandescent lamps. But further information on the accuracy with which temperature can be maintained is needed. The address also directs attention to the fundamental distinction between conceptions of light as radiation, and as a physiological impression—a distinction that becomes specially important when we have to deal with sources yielding light of different colour. The physiological phenomena affecting such comparisons are discussed, and some remarks are made on the results of "equality of brightness" and "flicker photometer" measurements. The visibility curve, throughout the spectrum, of the normal eye has now been ascertained with fair precision. A knowledge of this should enable us to evaluate the luminous power of any variety of radiant energy; and if, in addition, the primary standard based on the black body at specified temperature should prove satisfactory, considerable progress towards the scientific measurement of light will have been made.

Biometry and Genetics.

PROF. RAYMOND PEARL and his students continue to make important contributions to the biology of man and other organisms on a statistical basis. In a recent paper (Pearl and Bacon, Johns Hopkins Hospital Reports, vol. xxi. Fasc. iii.) an analysis is made of the relation of the relative size of heart, liver, spleen, and kidneys to tuberculosis. The data were derived from 1341 autopsies in which there were tubercular lesions. Six indices for the relative weights of the above organs were used as the basis of statistical investigation in relation to age, sex, race, and cause of death. It is shown that the relative weights of liver and heart, and heart and spleen change progressively during life; also that in cases of fatal tuberculosis the absolute weight of the heart is less and of the spleen greater than normal, probably because these changes are brought about by the disease. Curves of age show that when tuberculosis alone is fatal it kills at comparatively early ages. Many other interesting facts are brought out in this statistical study.

In "dry" America, experiments with alcohol have a particular interest. Stockard has shown with guinea-pigs and Pearl with fowls that individuals which throughout life received daily doses of alcohol by inhalation are much longer-lived than their untreated sibs. In a recent note (*Amer. Journ. Hygiene*, vol. ii. No. 4) Prof. Pearl points out that the actuarial data of insurance companies, which are generally supposed to show that the consumption of alcohol in man in any quantity shortens life, are practically worthless. From 1569 family history records carefully collected in the vicinity of Baltimore, he concludes that while heavy or steady drinking lowers the expectation of life, the moderate or occasional consumption of alcohol has no such effect on either sex.

In experimental studies on the duration of life in Drosophila (Pearl and Parker, *Amer. Naturalist*, vols. 55, 56) the authors compare the percentage of survivals at successive ages with the corresponding curve for man. A day in the life of a fruit-fly corresponds roughly with a year in the life of a man. Large numbers of flies of different stocks were bred under carefully standardised conditions. The length of the imaginal life was noted and the results compared with the statistics for man, beginning at the age of fifteen years. Fundamentally similar curves are obtained in the two cases. In Drosophila it is shown that long-winged flies have two or three times as great an expectation of life at any age as short-winged flies, and that other hereditary differences in duration of life also occur. The death-rates generally increase steadily with advancing age. The mortality curve for Drosophila is then compared with that for modern man and for the population of the Roman provinces in Africa about the beginning of the Christian era (from data of MacDonnell, *Biometrika*, 1913). The Drosophila curve generally runs intermediate between these two. The modern curve of human mortality is diverted from the normal by the prolongation of life of many of the less rugged by measures of public health and sanitation.

By selection and inbreeding from Drosophila stocks it was possible to isolate strains showing large differences both in mean duration of life and in the form of the mortality distributions, while in inbred lines the genetic differences remained constant for ten to twenty-five generations. It was shown that occasional etherisation of the flies has no appreciable effect in lessening their duration of life. There is some evidence that in crosses, duration of life may segregate like a Mendelian character. A pedigree indicating something of the same kind in man is presented by Pearl (*Amer. Journ. Hygiene*, vol. ii. No. 3). In the father's family only 10 per cent. survived to the age of fifty years, in the mother's family 75 per cent. reached that age, and in the offspring 87·5 per cent.

Using 100 births/deaths as a "vital index," Pearl and Burger (Proc. Nat. Acad. Sci. vol. 8, No. 4) plot the curve for this index for England and Wales in the years 1838–1920, from statistics in the Annual Reports of the Registrar-General. This ratio shows a slow but extremely steady increase until 1914, with only two slight fluctuations caused by influenza epidemics in 1847 and 1890. The birth-rate in the meantime showed a slow increase until about 1878, then a more rapid decrease until 1914, and a marked recovery since the war. Thus while in the year 1838–39 the number of births for each death was 1·4, in 1920 it was more than 2. The whole curve for the vital index shows a remarkably steady increment in the rate of population growth, with a high degree of regulation of death-rates to variations in the birth-rate. Measured by the criterion of the vital index, it is concluded that the population of England and Wales is "biologically more vigorous" than in 1838. But this merely means that its net rate of increase is greater, and takes no account of the differential character of the birth-rate. In another note in the same issue, Pearl considers the seasonal fluctuations in the vital index of the population, based on the same data, and finds that in each year it has its lowest value in the winter quarter (ending March 31), and its highest value in the summer quarter. In other words, in the winter months the birth incidence is relatively low and the death incidence relatively high, as might be expected.

That density of population influences fecundity was formerly shown for fowls, and similar results have now been obtained for Drosophila (Pearl and Parker, Proc. Nat. Acad. Sci. vol. 8, No. 7). The rate of reproduction of this fly is shown experimentally to vary inversely with the density of population. This is the converse of Farr's law that the death-rate varies directly with density of population. It is suggested that the world-wide increase in density of population may account for the general decline in birth-rates which has taken place in the last forty years. The subject is one which deserves further investigation.

A hexadactylous Norwegian family in which the postaxial digits (little fingers and toes) are double, is described by Aslaug Sverdrup (*Journ. Genetics*, vol. xii. No. 3). The condition is traced through six generations, and two types of polydactylism are recognised. In type A one finger, usually the fifth, is duplicated, while in type B the sixth finger is represented by a small attached appendage. Both these types are already well known. The condition behaves in general as a dominant character, but in one line of the family, showing chiefly the A-type, there is an excess, and in another, showing only the B-type, a deficiency of polydactyls. Moreover, an A-type individual may have either A- or B-type offspring, whereas B-types cannot produce A-types. It is concluded that the B-type is probably determined by a single Mendelian factor with sometimes a failure of dominance, while the A-type is probably due to cumulative factors. The A-type of polydactyly is sometimes accompanied in this family by a form of brachydactyly due to shortening of certain metacarpal bones, but also in some cases to short phalanges. Such papers on the inheritance of human abnormalities are important in their recognition of the necessity for accurate and detailed observations.

In a study of the inheritance of patching in the flower of the sweet pea Prof. Punnett (*Journ. Genetics*,

vol. 12, No. 3) introduces facts which cannot be explained on the ordinary Mendelian basis. The sweet pea Duke of Westminster sometimes has on the wings a larger or smaller patch of purplish pink. Such patched plants give normal, red, and patched offspring in varying proportions. Certain branches of "patched" plants are sometimes normal. The seeds from such normal branches show no constant genetic difference from the rest of the plant, nor was any evidence obtained that the normal, patched, and red flowers on a patched plant differed from one another genetically. There is no indication of genetic differentiation in the germplasm of different parts of the plant. Nevertheless, patched plants are not apparently all alike. As in striped Mirabilis, the pair of colour characters may behave either as a segregating Mendelian pair or form a mosaic. There is no sufficient explanation of this mosaic condition at the present time, but it represents a condition differing distinctly from ordinary Mendelian behaviour.

In a second paper on the inheritance of characters in some of the many rice varieties, Mr. F. R. Parnell, with the assistance of Messrs. G. N. R. Ayyanger, K. Ramiah and C. R. S. Ayyangar (Mem. Dept. Agr. India, Botany, vol. xi. No. 8), deals with the colours of glumes and grain, also with dwarfing and with shape of grain. The dwarf variety differs very markedly from the type, but behaves as a simple recessive. A result of economic importance is that the weight of the grain varies with the shape. The hereditary behaviour of a number of colour factors is analysed. Another genetic paper of economic value is a study of certain forms of cotton by Mr. Ram Prasad (Agric. Inst. Pusa. Bull. No. 137). Long fibre is considered to be a dominant character in cotton. Some evidence is obtained that long fibre is correlated with long stigma, plants with short lint having shorter styles. If this is the case it would enable roguing of undesirable plants producing short lint to take place much earlier than would otherwise be possible.

Norway and Iceland: An Interesting Contrast.

NORWAY has many interesting features to a visitor with scientific and technical tastes. The ubiquity of electricity generated from water-power has often been the subject of comment. The peculiar formation of the high tablelands, with lakes at heights of 1000-3000 feet, constantly renewed by water from the snows above, is favourable to hydro-electric supply. The potential value of the water-power of Norway has been assessed at 15,000,000 h.p., of which about one million is at present in use.

The mountainous nature of the country has other interesting consequences. One curious result is that communication between valleys is often less easy in summer than in winter, when roads and passes become covered with deep snow and can be traversed by ski and sleigh. The nature of the country has developed isolated scattered communities with pastoral tastes and special local industries, such as the hand-woven fabrics for which Norway is famous.

The climate has much in common with that of England. Bergen is notorious for its rainfall, and the humid atmosphere is doubtless responsible for the luxuriant growth of trees, springing in masses out of the bare rock lining the fiords in a manner that seems to invite study by experts in forestry. The use of timber in Norway is universal. Buildings are almost invariably of wood, and the humbler cottages are roofed with turf, which seems to thrive in the moist atmosphere. In mountainous Norway grass is scarce. Hence the custom of sending cattle up to the mountain "sæters" in the summer, so that the grass at the level of the fiord can be stored in summer-time. This cut grass is hung up to dry on horizontal lengths of wire. Possibly British farmers could take a hint from this practice, as crops in this country are often spoiled by rain.

Geologically the great tablelands of Norway, with their stretches of perpetual snow at relatively low level, and their vast glaciers (the largest in Europe with the exception of those in Iceland) are of great interest. It is a strange sight to find these great glaciers descending right down to the level of the fiord, as happens, for example, at Fjaerland.

Iceland furnishes some interesting contrasts to Norway. The climate is more stable and less like that of Britain. Whereas in Norway trees are everywhere, in Iceland there are practically none. Hence we find a new material for buildings of the better class—corrugated iron! Grass is also scarce, and Iceland is one of the few countries where rabbits will not thrive. The scenery, though almost destitute of verdure, is not monotonous and has a charm of its own. It consists mainly of alternations of rock, lava, and sand, with, on the lower slopes of mountains, stretches of moss. All vary remarkably in colour. Rocks are black, brown, purple, and occasionally bright red. Sand may have any tint from yellow to black. Amazing changes in colour, difficult to explain and offering an interesting study to the physicist, occur as the sun sets. A curious feature is the astonishing brilliancy of the setting sun, exceeding by far that usual in England. The pools of molten lava also afford a field for study. Their position is indicated by a sulphur-yellow crust, but the upper liquid contents are often bright blue, changing to scarlet at a lower level. Hecla, by the way, although the mountain best known to English readers, is by no means the best example of volcanic action, and is a comparatively inconspicuous mountain.

Ice and snow, usually not far distant in Norway, are universal on the higher mountains of Iceland, and the blanket of ice and snow creeping over the edges of precipices forms an important element in the general scheme of coloration.

In one respect Iceland and Norway seem to be much alike—in the hospitality accorded to the English visitor. In Norway, especially when one leaves the beaten track, one is conscious of an atmosphere very different from that in many hotels in Europe. In Iceland, once he leaves the capital, the traveller finds practically no hotels, but he can rely on the generous hospitality of the districts visited. Ponies are the usual mode of conveyance. It is stated that the import of horses is forbidden, as the Icelandic Government desires to keep the strain of ponies pure.

In Norway the present writer was impressed by the high general level of education. One could converse on equal terms with persons of all degrees, and learn facts of interest about the country. English is a compulsory language in the schools, and is often spoken with considerable facility. Even in Iceland, it appears, English is spoken more frequently than might be expected. Here again there is a high level of education, but owing to the remoteness of the island some strange conceptions of England prevail.

In Iceland, as in Norway, a variant of Danish is

spoken. But whereas in Norway the entrance of foreign words is not resented, in Iceland they invariably undergo translation before acceptance. The writer was given to understand that the language is written and spoken in almost exactly the same manner as it was a thousand years ago, and that the ancient sagas can be read with the same ease as the modern newspaper. Probably there is no other country in Europe where this strange perpetuation of ancient forms of speech prevails.

The Survey of India.

THE report by Col. Ryder, the present Surveyor-General of India, referred to below,[1] shows that in the year 1919–20 the Indian Survey Department had fully recovered from the dislocation due to the War.

During this period there were no less than 19 survey parties in the field, of which 12 were topographical. On the normal scale of one inch per mile (much of which was revision) and smaller geographical scales, about 2800 square miles was turned out, while on the larger scales, ranging from 1½ inches to 24 inches and even 64 inches (city and town surveys), the output, detailed partly in miles and partly in acres, was reckoned to be satisfactory. Every class of country was included in the field of work, from the sands of Rajputana to the dense forest-covered hill tracts of Burma, and we read of the time-old difficulties, heavy and continuous rain, malaria, and even of the clearance of villages by man-eating tigers. It is interesting to observe that the sources of the Irawadi (so long a geographical problem) were finally mapped.

Although the costs of the different classes and scales of survey are set out in considerable detail, it is difficult to frame any conclusion as to whether those costs have risen since the War. The normal one-inch scale of original survey apparently varied between 20 Rs. per square mile in Bengal and 70 Rs. in Lower Burma. This does not indicate any great increase on pre-war costs, but in itself scarcely justifies any general estimate.

In the geodesic and scientific branch of the department there is a curtailment of activity. No first-class triangulation was carried out, and both the pendulum and latitude observations were suspended, but the registrations of tidal curves by means of self-registering tide-gauges were continued at Aden and at the principal ports of India. Levelling operations were also continued, and a new geodesic level net of India has been inaugurated on which levelling of high precision on the "fore and back" system will be the method employed. Like the exact determination of the height of the principal peaks of the Himalaya, it might be open to question whether the practical results of extreme precision are worth the expense of determination. The magnetic survey was also carried on during this season. The report closes with the usual returns of the computing- and drawing-offices.

The chief point of interest in the volume is found in Appendix II.—the report on the expedition to Kamet by Major Morshead, who afterwards took such an active part in the Everest expedition. Kamet (25,445 feet high) is the culminating peak of the Zaskar range, and afforded Major Morshead and that distinguished mountaineer, Dr. Kellas, an excellent opportunity for scientific observation on the effect of high altitudes on the human body. Appendix III. is also interesting, recording a note on the topography of the Nun Kun massif in Ladakh by Major Kenneth Mason. He has a good deal to say in criticism of Mrs. Bullock Workman's claim to have established the height and position of certain peaks of that group, in which she disagrees with Indian Survey results. It is always dangerous for the amateur to claim greater accuracy than that maintained by the Trigonometrical Survey of India. Mrs. Bullock Workman, in publishing her account of her extraordinary feats of climbing, pits herself against the G.T.S. and suffers accordingly.

T. H. H.

Polish Celebrations of the 450th Anniversary of the Birth of Copernicus.

NICOLAUS COPERNICUS was born on February 19, 1473, in Toruń (Thorn), a town situated on the Vistula, in the north-west of Poland; the 450th anniversary of the birthday of the great astronomer occurred thus on Monday, February 19, and was celebrated in many parts of Poland with much solemnity. Impressive ceremonies were held in Warsaw, Wilno, Poznań, Lódź, Wloclawek, and Kieke; in the Jagellonian University of Cracow (where for four years, 1491–1495, Copernicus was an undergraduate) the celebrations in commemoration of the anniversary will be held at a later date, probably in May.

In connexion with the Cracow proceedings a work, "Stromata Copernicana," will be published under the auspices of the Polish Academy of Sciences and Letters in Cracow; its author is Prof. L. Birkenmajer, the well-known biographer of Copernicus. We have not the space to enter into an account of Prof. Birkenmajer's investigations, but the following interesting fact may be mentioned: On the October page for the year 1505 of the book "Calendarium Magistri Joannis de Monte Regio," preserved in the Uppsala University Library (sign. "Incunab." 840), Prof. Birkenmajer discovered, in Copernicus's well-known handwriting, the Polish inscription (twice repeated) "Bok pomagay" (Our Lord, help us). Writing on this interesting detail, Prof. Jan Loś, the well-known philologist (and professor of the history of Polish language in the Jagellonian University of Cracow), says: "In the year 1505 every Pole would have written the words given above exactly in the form in which Copernicus has written them" (*Jezyk Polski*, vol. viii., No. 1). Prof. Birkenmajer adds that in 1505, or perhaps in 1506, Copernicus had already in his mind the ideas which eventually took form in the well-known revolutionary "Commentariolus."

The Copernicus commemoration at Toruń extended over the two days—February 18 and 19; delegates from all the universities, high schools, scientific societies, etc., of Poland, and other guests were cordially received by the municipality and citizens of Toruń. The proceedings included the inauguration of the first general meeting of the Polish Astronomical Society. This meeting resolved unanimously to ask the Polish nation to establish a National Astronomical Institute in Poland; an attempt with this object in view was made by Prof. Banachiewicz, of the Jagellonian University of Cracow, and exists in the form of an astronomical station in the Carpathian Mountains. A memorial tablet on the house where Copernicus was born was also unveiled.

Pathology of Market Produce.

DURING recent years great efforts have been made by the biologist to gain such a knowledge of the diseases of cultivated crops as will permit methods of control to be placed at the disposal of the grower.

A reference to the pages of the *Annals of Applied Biology*, the official organ of the Association of Economic Biologists, together with the number of other papers published each year dealing with the life history of disease-producing organisms infecting plants, will show that considerable progress has been made in this still comparatively new field. But some brief papers published in *Phytopathology*, the official organ of the American Phytopathological Society, will show that in the United States a new field of scientific investigation has been opened between the crop and the consumer. Much of the produce, especially of market garden and greenhouse, is extremely perishable, and the cost of fruit or vegetables to the consumer is largely contributed to by the heavy loss that occurs during transit and marketing.

In 1917 in the States a Food Products Inspection Service of the Bureau of Markets was established and was soon working in close collaboration with the trained investigators of the Bureau of Plant Industry.

As is pointed out by G. K. K. Link and M. W. Gardner in a brief review of the first year's work that resulted from the joint attack upon the pathology of market crops (*Phytopathology*, 9, pp. 497–520), the first result was a revelation of the enormous economic importance of the problem, to which the long distances of transit in the United States naturally contributed. In water-melons alone, from four States during 1918, the market inspection services record a loss of 1¼ million dollars, while hundreds of car loads of grapes from California were almost a total loss, due to decay induced by Botrytis, Penicillium, and Aspergillus. Furthermore it was found that these losses, stoically borne by the trade as "part of the game" and passed on to the consumer, very largely arose from preventable causes, with the result that pathologists are being pressed to extend their survey from the growing crop to the study of the crop during harvesting, storing, shipping, and marketing.

Another line of biological inquiry has also been indicated: the task of salvage when prevention of loss is no longer possible. Most of these diseases are fermentation processes, and a controlled fermentation may yield a by-product of value. At the outset the market pathologist has found himself forced to recognise almost a new type of disease organism. Under field conditions this type has limited importance, but under market conditions the plant tissues are less resistant and these organisms show much greater virulence while attacking a wide range of plant species; among such organisms are found the bacterial soft rots and Botrytis.

The American pathologist has already reached the stage at which his first survey enables him to indicate to grower and salesman the most harmful types of disease, the characters by which they may be recognised by the non-expert eye, the conditions leading to the spread of these diseases and the most practicable methods for their control during transport and storage. It may be argued that in Great Britain, the small distance involved in transit renders the question of less importance. But short distances do not always mean rapid transit, and in any case, the most casual inspection of a fruit and vegetable market would show that American experience in this question may be of real value.

Of general application also are such results of the preliminary American work as their experience with strawberries, where N. E. Stevens finds (*Phytopathology*, 9, pp. 171–177) that strawberries picked early in the day, even if wet, keep better than those berries picked after the sun has been on them for some hours. Pomologists also will be quick to admit that we have still to learn the reasons for the different keeping qualities of the same variety of apple if gathered under different conditions. Under the stimulus of war conditions very great progress was made in Great Britain in the investigation of food storage conditions, and as a consequence some attention has been paid in recent scientific communications to the organism found causing damage among stored produce. American experience, however, would seem to raise the more general question whether the phytopathological experience of the investigator should not be re-orientated so as to embrace the whole history of the vegetable, from field to table.

The Eruption of Sakura-jima in 1914.

PROF. OMORI has recently (*Bull. Imp. Earthq. Inves. Com.*, vol. 8, pp. 467-525) published his sixth, and apparently last, memoir on the eruption of Sakura-jima of January 12, 1914, and following days—the greatest of all known eruptions in Japan, if greatness be measured by the amount of lava outflow and ash precipitation. The six memoirs fill a volume of 525 pages and are illustrated by 107 plates. They constitute, according to the author, "a modest geometrical and seismological report on the great Sakura-jima eruption of 1914, and the course of the after-events followed for the next 8 years." Prof. Omori's readers will, I imagine, take a somewhat different view. They are more likely to regard the volume as the finest monograph, from a physical point of view, that has ever yet been written on a volcanic eruption.

Summaries of previous memoirs have from time to time appeared in these columns.[1] The first (September 1914) contains a general account of the eruption and its accompanying phenomena. The second memoir (April 1916) deals with the sound and ash-precipitation areas of the eruption, the accompanying changes of level and the earlier outbursts of the volcano. The third (December 1916) summarises the subsequent course of activity. After a pause of more than three years, the fourth memoir (March 1920) appeared containing the results of the levelling surveys and the soundings in Kagoshima Bay made after the eruption. The fifth part (March 1920) is devoted to the seismographical observations of the fore-shocks and after-shocks, while the sixth (November 1922) deals chiefly with the destructive earthquake of January 12, 1914.

The interest of this earthquake lies in its occurrence during the eruption about 8½ hours after it began. It was clearly a tectonic, and not a volcanic, earthquake. Instead of being a sharp brief shock of small disturbed area, the movement at Kagoshima was of considerable strength and duration; it was felt for about 220 miles to the N.E. and S.S.W., and was strongly registered by European seismographs.[2] The epicentre was situated in the Kagoshima channel, about 4 km. south-east of the observatory in that

[1] Vol. 94, p. 289; vol. 98, pp. 57-58; vol. 100, p. 35; vol. 106, pp. 165-166.

[2] NATURE, vol. 92, 1914, p. 717.

city. Judging from the duration (1·9 seconds) of the preliminary tremor, Prof. Omori infers that the focus was distant 14 km. from the observatory and therefore at a depth of 13 km. Numerous stone-lanterns and tombstones were overthrown in Kagoshima, the average direction of their fall being N. 68° W., which agrees roughly with the direction of the first movement registered in the same place. The trigonometrical re-survey of the district revealed horizontal movements since the eruption began of 2·62 to 4·52 metres to the north-east and north in the north and north-west parts of the island, while new soundings made in the north part of Kagoshima Bay showed that the floor of the bay had sunk from one-half to four fathoms, except in two spots in which a rise of from one to three fathoms had occurred. An hour or a little more after the earthquake, small sea-waves or *tsunami* swept over the shore at Kagoshima. At about the same time or later, the cable from Kagoshima to Sakura-jima, which crosses one of the elevated spots, was fractured on the flat bottom of the channel about one-third of its width from the coast of the island. Prof. Omori points out that it was not a single clear fracture, such as might have been formed if the application of the tension had been instantaneous, but that numerous breakages occurred over a length of 420 feet, the average distance between successive breaks being 1·7 feet. He infers that the horizontal and vertical movements of the sea-bed took place gradually.

The occurrence of a great tectonic earthquake in a volcanic district and during the progress of an eruption is somewhat rare. Prof. Omori gives some other examples from Japan in this memoir. Their connexion with the corresponding eruptions can scarcely be doubted. It seems equally clear that they do not owe their origin to the volcanic outburst itself, but that eruption and earthquake are both effects of the same deeply-seated cause.

C. DAVISON.

Fishery Research in Lancashire.

THE report on the scientific fishery investigations carried out under the auspices of the Lancashire and Western Sea Fisheries District Committee during the year 1921, which is edited by Prof. James Johnstone, the honorary director of the scientific work, is characterised by the extremely cautious way in which it has been drawn up. While the absence of very definite conclusions must to some extent be a matter for regret, it has to be admitted that the amount of evidence collected, though very extensive when considered in the aggregate, is still insufficient to make any other course possible for a highly-trained and critical mind. Like so much of the valuable fishery work which has been accomplished during the last twenty or thirty years, these investigations have tended to show how exceedingly complex the problems may become, and how difficult it is to get together data sufficiently varied in character and in sufficient quantities to provide material for their solution. The investigations do, however, afford clear indications of the lines upon which future research should proceed and make it certain that many of the questions discussed may be answered in the future, if the necessary facilities can be provided on an adequate scale.

The two most important articles in the report deal with the plaice and the herring. The plaice investigations were commenced in 1908 and were specially extended in 1919–21. They are now summarised for the whole period in a series of tables which include all the data. These tables will have a permanent value as a record of the condition of the plaice population, and will be invaluable for comparison with the results obtained in future years. The discussion of the data is limited to broad general features, and is directed throughout to show the bearing of the work on the actual practical problems with which the Sea Fisheries Committee is called upon to deal.

The herring work is of a more technical statistical character, and it is difficult to avoid a feeling of regret that so much work in mathematical analysis has been carried out upon samples containing for the most part only 50 fish. The work, it is true, is preliminary, and it will probably be found more profitable in the future to examine fewer samples and fewer characters but with very much larger numbers of fish.

Mention must be made of Mr. R. J. Daniel's work on the chemical composition of mussels, especially on the substance which has been called "glycogen" in these shell-fish. It is most important that these biochemical studies should be continued, for they promise results of much interest.

The report of the Marine Biological Station at Port Erin for 1922 has also been published recently. The most important paper in this report is by the late Prof. Benjamin Moore, in co-operation with Messrs. E. Whitley and T. A. Webster, on the subject of photo-synthesis in marine algæ. The authors show that green, brown, and red algæ are arranged on the shore so that each kind is in that intensity of illumination which is the optimum for the colour scheme of chromophylls it possesses. In strong illumination, green algæ synthesise far more rapidly than red, but in weak illumination the red algæ synthesise more rapidly than green. The brown algæ are intermediate in their action.

The two reports reflect credit both on those responsible for the organisation of the investigations and on those who have carried them out.

University and Educational Intelligence.

ABERDEEN.—By the bequest of the late Miss Anne Hamilton Cruickshank in 1911, a sum of money was set aside for the foundation of a chair in astronomy. The special trustees have now reported to the University Court that the accumulated sum available exceeds 15,000*l.*, and have recommended the foundation of a chair, or lectureship, in astronomy, including navigation and meteorology. The recommendation is under consideration by a committee of the Court. Miss Cruickshank was the daughter of John Cruickshank, professor of mathematics in Marischal College and University from 1817 to the union of the Universities in 1860. Miss Cruickshank also founded the Botanic Gardens and the Cruickshank Law prize, while the Science Library of the University is associated with her name.

Notice is given that the Blackwell Prize Essay, value 30*l.*, and open to all, will be awarded in 1924 for the best essay on "The History of the Fishing Industry of the Port of Aberdeen since 1800," provided any essay sent in is of sufficient merit. Each essay (which must bear a motto and be accompanied by a sealed envelope bearing the same motto and enclosing the name and address of the sender) must be sent to reach the Secretary of the University not later than January 1, 1924.

CAMBRIDGE.—A Bill has been presented to the House of Lords appointing Statutory Commissioners for the Universities of Oxford and Cambridge to make

statutes and regulations in general accordance with the recommendations contained in the recent Report of the Royal Commission. The Cambridge Commissioners named in the Bill are Viscount Ullswater (chairman), Bishop Ryle, Sir Thomas Heath, Sir Richard Glazebrook, Sir Henry Wilson, Sir Hugh Anderson, Dr. Peter Giles, Mr. William Rendell, and Dr. Hugh Dalton. It is perhaps significant of the difference between the two Universities that the only Fellow of the Royal Society among the Oxford Commissioners is Sir Archibald Garrod, Regius professor of medicine. A few only of the provisions in the Bill can be selected for mention here. In making statutes the Commissioners are to have regard to the main design of the founder of any institution or emolument affected by the statute. In the case of a statute affecting a college they are to have regard to the maintenance of the college in the interests of education, religion, learning, or research. In particular, in prescribing the scale or basis of assessment of contributions made by the colleges to University purposes, regard is to be had in the first place to the needs of the several colleges in themselves for educational and other collegiate purposes. It is not desired in reforming Oxford and Cambridge to reform away the peculiar characteristics which have built up their present strong position in the world of education, religion, learning, and research.

Dr. G. S. Graham Smith, Pembroke College, has been appointed reader in preventive medicine; Dr. J. T. MacCurdy, Corpus Christi College (also of Toronto and Johns Hopkins Universities), has been appointed University lecturer in psychopathology; J. Mills, research student, Gonville and Caius College, has been elected to the Nita King research scholarship in the etiology, pathology, and prevention of fevers.

LONDON.—The latest date for the receipt of applications for grants from the Dixon Fund for the assistance of scientific investigations is May 14 next. Applications, accompanied by the names and addresses of two references, must be sent to the Academic Registrar, University of London, South Kensington, S.W.7.

DR. ETHEL N. MILES THOMAS, fellow of University College, London, has been appointed lecturer in botany and zoology at University College, Leicester.

THE *Times* announces that Sir Walter Buchanan, a pioneer of the frozen-meat export industry, has given 10,000*l.* for the establishment of a chair of agriculture at Victoria College, Wellington (N.Z.).

THE University of Budapest announces that summer courses will be held this year from August 1 to September 15 under its auspices. Lectures will be given by members of the faculties of theology, law, medicine, arts, and economics. Full prospectuses are in preparation.

THE Government of Western Australia has allocated a special grant this year for the commencement of the permanent buildings of the University of Western Australia, Perth. As recommended by the professorial board, the science departments will be the first to be removed to new premises, and the present grant for the period ending June 30, 1923, is for the provision of a joint building for the biology and geology departments. The next buildings to be erected will be those for chemistry and for physics. The new site for the University is at Crawley, and covers an area of about 160 acres. The science buildings will be placed on high ground adjoining the national reserve of King's Park, and their southern frontages will command a splendid view of the broad sheet of Melville Water on the Swan River.

WE notice that numerous appeals have been issued by professors in Germany for money for institutions for higher education and research, such as the Emperor William Institute for Physics, the English Seminary in Berlin University—by Prof. Alois Brandt, who advocates the compulsory teaching of English in all the higher public schools of Germany—the Cancer Research Institute, the Seminary for Christian Archæology, the Egyptian Seminary, and the High School of Jewish Studies. It is stated that a good deal of political recrimination has found its way into the appeals. Whatever may be thought of the policies of the German Government since the War in other respects, it cannot fairly be charged with failure to appreciate the vital importance of education. We have excellent authority for believing that throughout its financial difficulties Germany has had no disposition to economise in its educational expenditure. The universities, as was pointed out in these columns some months ago, were never depleted of students during the War to anything like the same extent as ours, while since the War they have been filled to overflowing; but the appeals would seem to indicate that the Government has been less generous to institutions for higher education and research than to the elementary and secondary schools and the new "People's High Schools." The depreciation of the mark has of course led to difficulties in the way of obtaining English books and periodicals, and these have been to some extent met by a system of exchange with British universities established last year by the Universities Bureau.

THE twenty-first annual meeting of the Carnegie Trust for the Universities of Scotland was held on February 14, Lord Sands presiding. The original endowment fund of 2,000,000*l.* has been increased by 547,000*l.*, in addition to which there are reserve funds amounting to nearly 183,000*l.* Expenditure for the year ended September 30, 1922, amounted to 125,292*l.*, including: assistance in payment of class-fees, 61,217*l.*; grants to universities and colleges for buildings, lectureships, libraries, etc., 44,925*l.*; encouragement of post-graduate study and research, 17,063*l.*; annual grant to women students' union, 250*l.*; management expenses, 5193*l.* Post-graduate study and research were encouraged by fellowships, scholarships, and prizes (6958*l.*), grants towards salaries of part-time research assistants (3600*l.*), grants to the Laboratory of the R.C.P., Edinburgh (2740*l.*), to St. Andrews Institute for Clinical Research (1000*l.*), and other grants (2765*l.*). Arrangements were made with the Department of Scientific and Industrial Research for the simultaneous consideration of applications. During the year sums amounting to 1387*l.* were voluntarily repaid by or on behalf of 39 beneficiaries, making a total of 12,583*l.* repaid since 1901. The repayments by women exceeded those by men for the first time both in number and total amount. In the annual report of the Carnegie Corporation of New York, issued a few days earlier than the Scottish report, stress is laid on the dangers and difficulties incidental to the administration of all such charitable foundations and the necessity for the exercise of careful discrimination and constant watchfulness for the harmful as well as the beneficial results of giving. Among the former it mentions the overcrowding of the colleges with students, many of whom would find their greatest happiness in other vocations than those to be sought through college training.

Societies and Academies.

LONDON.

Zoological Society, March 20.—Prof. E. W. MacBride, vice-president, in the chair.—S. Ch. **Sarkar**: A comparative study of the buccal glands and teeth of opisthoglyph snakes, and a discussion on the evolution of the order from Aglypha.—Oldfield **Thomas** and M. A. C. **Hinton**: On the mammals obtained in Darfur by the Lynes-Lowe expedition.—R. I. **Pocock**: (1) On the external characters of Elaphus, Hydropotes, Pudu, and other Cervidæ. (2) The classification of the Sciuridæ.

The Optical Society, March 22.—Instr.-Commander T. Y. Baker in the chair.—Dr. L. C. **Martin**: Surveying and navigational instruments from a historical standpoint. Before A.D. 150 accurate knowledge of the Mediterranean basin was obtained by Ptolemy. One of the best known of the early instruments was the astrolabe, and this instrument was developed considerably by the Arabs and others. Specialised forms were used for navigation. In the seventeenth century a simplified form of the astrolabe, capable of being suspended or mounted horizontally on a stand, was employed as a theodolite. This was subsequent to the description of Digges's *theodolitus*, in which independent horizontal and vertical axes were employed. The use of the telescopic sight was not applied to surveying instruments till the beginning of the eighteenth century. The history of the level, from the "open sight and gravity controlled" forms to the telescopic levels of Picard and the bubbles of Thévenot, was also discussed. Improvements by various artists in the methods of graduation of circles and the development of dividing engines from Hindley to Ramsden and Troughton were matters of the greatest moment in the development of modern instruments. Later developments were shown in the instruments by Troughton and by Cary, which brought the level of construction (from the purely scientific point of view) almost up to that of our own time.

CAMBRIDGE.

Philosophical Society, March 5.—Mr. C. T. Heycock, president, in the chair.—Sir Ernest **Rutherford**: The capture and loss of electrons by α-particles. In a recent paper (Proc. Roy. Soc. A, 102, p. 497, 1922) G. H. Henderson showed that swift α-particles can capture electrons and are thus converted into singly charged and neutral helium atoms. The magnetic deflexion of a pencil of α-rays in a high vacuum showed by the photographic method after passing through mica the presence of two bands—one, the main band, due to He + +, and the other, the midway band, due to He + particles. The relative number of the latter increased rapidly with reduction of velocity of the α-rays. These conclusions have been confirmed by the scintillation method. By deflecting the midway band by a combined electric and magnetic field, it has been proved that it is due to He + particles. For any velocity there is a temporary equilibrium between the number of He + + and He + particles, such that the number of captures is equal to the number of losses. The ratio of the numbers of singly and doubly charged particles between the velocities $7{\cdot}7 \times 10^8$ and 18×10^8 cm. per second, varies approximately as the inverse fifth power of the velocity. The disappearance of the midway band when gas at low pressure is introduced in the path of the rays gives a method of determining the mean free path of the He + particles in air and other gases before conversion into He + +. The mean free path varies roughly as the velocity of the α-rays, and is 4 to 5 times longer in hydrogen and helium than in air. The mean free path for capture varies roughly as the inverse sixth power of the velocity. The mean free path in air for a velocity $1{\cdot}5 \times 10^9$ cm. per sec. is about 0·56 mm. at N.T.P. for capture and 0·008 mm. for loss. The average α-particle captures and loses an electron many hundred times before it is absorbed. —P. **Kapitza**: Some observations on α-particle tracks in a magnetic field.—H. **Lamb**: The magnetic field of a helix.—W. **Burnside**: (1) The theory of errors of observation; (2) The solution of a certain partial difference equation.—P. M. S. **Blackett**: A note on the natural curvature of α-ray tracks. An apparent relation exists between the plane and direction of the curvature of the parts of a forked track and the plane and type of the fork itself. The natural curvature possibly involves the effect on the ionisation of the probable assymmetric structure of singly charged α-particles.

SHEFFIELD.

Society of Glass Technology (Birmingham meeting), March 21.—Prof. W. E. S. Turner in the chair.—H. S. **Blackmore**, Violet **Dimbleby**, and W. E. S. **Turner**: A rapid method of testing the durability of glassware. When a very dilute solution of 1 part in 1000 of the alkaloid, narcotine hydrochloride, is heated to boiling-point inside a glass vessel, the alkaloid is thrown out of solution, and can be seen as a fine precipitate if the glass is of poor quality. Good glasses should show no sign of deposit when heated at the boiling-point for an hour.—D. **Turner** and W. E. S. **Turner**: The corrosion of fireclay refractory material by glass and glass-making materials.—Edith M. **Firth**, F. W. **Hodkin**, and W. E. S. **Turner**: The effect of saltcake in corroding fireclay materials. Both papers were presented by Prof. Turner. Experimental evidence was detailed, showing that in glass-melting the corrosion of the pots or the tank blocks is most severe during the early stages of the melting of the batch; sodium nitrate, potassium nitrate, and borax are particularly corrosive. As the proportion of saltcake used in the batch increased, so did the extensiveness of the corrosion. Resistance to corrosion can be improved by firing the pots and blocks at 1400° C. before the charge of batch was inserted

PARIS.

Academy of Sciences, March 19.—M. Albin Haller in the chair.—The president announced the death of M. Van der Waals, foreign associate.—Emile **Borel**: The approximation of rational or incommensurable numbers belonging to given enumerable ensembles.—L. **Lecornu**: The time of revolution of the planets. A discussion of a question raised in a recent note by M. Jean Chazy.—Charles **Moureu** and Charles **Dufraisse**: Auto-oxidation and anti-oxygenic action. The catalytic properties of iodine and its compounds. The case of acrolein. According to the theory of the mechanism of anti-oxygenising action developed by the authors, iodine and its compounds should exert catalytic properties in phenomena of auto-oxidation, and should, under certain conditions, possess the anti-oxygenising property. Iodides of various metals and organic bases (33 in all) were shown to inhibit the oxidation of acrolein at a concentration of 1 in 1000.—L. **Maquenne**: The hydrolysis of maltose by malt extract.—G. **Gouy**: The improvement of the microscope by the

use of X-rays.—C. **Guichard**: Triply indeterminate systems of spheres, circles, and double points.—Jules **Andrade**: An arrangement of four regulating springs producing a constant friction and a quadratic friction.—J. B. **Senderens**: The catalytic dehydration of alcohols by dilute sulphuric acid. Both the ether and substituted ethylene can be prepared by the action of sulphuric acid on the corresponding alcohol, and the ratio of ether (alkyl oxide) to ethylene can be varied by the addition of water to the acid.—Ph. **Glangeaud**: A trial boring for petroleum at Crouelle, near Clermont-Ferrand (Puy-de-Dôme). The boring was taken down to 856 metres, and full details of the strata met with are given. At 596 metres there was a strong evolution of inflammable gas and about a ton of a heavy oil was collected (density 0·963, sulphur 9·3 per cent.). More oil, in smaller quantities, was obtained at greater depths. The tube was broken by an accident at 787 metres.—M. Emanuele **Paterno** was elected foreign associate, in succession to the late Prince of Monaco.—Georges **Bouligand**: Some points in functional analysis.—W. **Margoulis**: The general theory of the representation of equations by means of mobile elements.—J. **Haag**: The problem of n bodies in relativity.—Henry **Hubert**: A method, considered as new, for the stereoscopic representation of topographical surfaces.—R. **Dufour**: High frequency induction furnaces.—A. **Leduc**: A new improvement of the equation of state of gases.—Léon and Eugène **Bloch**: Spark spectra of higher order. A study of the spectrum of mercury obtained by the oscillating discharge in a silica tube without electrodes. The appearance and number of lines change as the voltage increases.—C. E. **Guye**: The kinetic interpretation of the rule of van't Hoff.—Réne **Audubert**: The action of gelatin upon concentration cells. A study of the effect of the progressive addition of gelatin on the E.M.F. of the concentration cells $AgI—AgNO_3$; $AgCl—AgNO_3$; $Ag_2S—AgNO_3$. The results appear to show that the Ag ion is adsorbed by the gelatin.—L. **Bert**: A new synthesis of cumene and p-cymene. Isopropyl sulphate reacts with C_6H_5MgBr giving cumene: the magnesium derivative of p-bromotoluene with isopropyl sulphate reacts similarly, giving p-cymene.—Emile **André**: The acid-alcohols contained in the oil from grape stones.—Henry **Joly**: Some peculiarities of the Bajocian in the neighbourhood of Montmédy (Meuse).—Ch. **Maurain**: Magnetic measurements in Brittany. The results of observations made at forty-one stations in August and September 1922, and the magnetic elements (declination, inclination, and horizontal component) reduced to January 1, 1922.—Filippo **Eredia**: The temperature of the air in the province of Tripoli.—L. **Blaringhem**: New facts relating to the hybrids of wheat and Ægilops.—H. **Colin** and Mlle. Y. **Trouard-Riolle**: Dissociation of the hybrid: smooth-bearded black barley and Albert barley.—Lucien **Daniel**: Regeneration of the potato by grafting. An account of attempts to increase the resistance to disease of the potato by grafting on tomato. The experiments have given promising results.—A. **Polack**: The accommodative compensation of the chromatism of the eye. Insufficiency of d'Alembert's theory.—L. **Garrelon** and D. **Santenoise**: Relations between the resistance of the organism to poisons and the rapid modification of the oculo-cardiac reflex. Contribution to anti-anaphylaxy.—Marc **Romieu**: Contribution to the comparative histology of striated muscle.—Mme. J. Samuel **Lattès**: The physical conditions which accompany the phenomenon of necrosis produced by radium radiation.

Diary of Societies.

MONDAY, APRIL 16.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge, Kensington Gore), at 5.—W. Irwin: The Salts of the Dead Sea and River Jordan.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. Shattock: Demonstration of Specimens Illustrating Repairs of Fractures.

BRITISH PSYCHOLOGICAL SOCIETY (Industrial Section) (at University College), at 6.—Dr. G. H. Miles: Rest Pauses.

ROYAL SOCIETY OF ARTS, at 8.—E. Kilburn Scott: The Fixation of Nitrogen (2). (Cantor Lecture.)

CHEMICAL INDUSTRY CLUB (at 2 Whitehall Court), at 8.

TUESDAY, APRIL 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Arthur Keith: The Machinery of Human Evolution (2). How Old Structures are Lost.

ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting.

ROYAL STATISTICAL SOCIETY, at 5.15.—Dr. E. C. Snow: Trade Forecasting and Prices.

ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 5.30.

INSTITUTION OF CIVIL ENGINEERS, at 6.—Special General Meeting.

INSTITUTE OF MARINE ENGINEERS, INC., at 6.30.—R. Clark: The Operation of Water-tube Boilers for Cargo-Passenger Ships.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—J. C. Dollman: Difficulties in Painting and Photography.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Miss Tyra de Kleen: The Ceremonial Dances and Magic Rites of the Island of Bali, Dutch East India.

WEDNESDAY, APRIL 18.

ROYAL METEOROLOGICAL SOCIETY, at 5.—W. H. Dines and L. H. G. Dines: An Examination of British Upper Air Data in the Light of the Norwegian Theory of the Structure of the Cyclone.—Tatuo Kobayasi: The Mechanism of Cyclones and Anti-cyclones.—Capt. E. C. Shankland: Notes on the Fluctuations of Mean-sea-level in Relation to Change of Atmospheric Pressure, from Observations at Liverpool, August and September 1920.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—J. F. N. Green: The Structure of the Bowmore-Portaskaig District of Islay.

ROYAL MICROSCOPICAL SOCIETY, at 8.—D. W. Cutler: The Protozoa of the Soil.—Prof. A. C. Seward: The Use of the Microscope in Palæobotanical Research.

THURSDAY, APRIL 19.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. O. Rankine: The Transmission of Speech by Light (2).

LINNEAN SOCIETY OF LONDON, at 5.—E. Heron-Allen and A. Earland: The Foraminifera of Lord Howe Island, South Pacific.—The General Secretary: The History of Botanic Illustration in Colour during Four Centuries.

INSTITUTION OF MINING AND METALLURGY (at Geological Society of London), at 5.30.

SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS (at Essex Hall, Strand), at 8.—C. E. Pell: Is the Fall in the Birth-rate a Natural Law?

CHEMICAL SOCIETY, at 8.—R. Ibbotson and J. Kenner: The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. Part VII. Reactions of 2:5- and 4:5-dinitro-*m*-xylene.—S. F. Birch, G. A. R. Kon, and W. S. G. P. Norris: The Chemistry of the Three Carbon System. Part I. The Influence of the *Cyclo*hexane Ring on the $\alpha\beta$-$\beta\gamma$ Change.—S. Medsforth: The Promotion of Catalytic Reactions. Part I.

FRIDAY, APRIL 20.

ROYAL SOCIETY OF ARTS (Dominions and Colonies and Indian Sections), at 4.30.—Sir Richard A. S. Redmayne: The Base Metal Resources of the British Empire.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: The Shape and Relationships of the Stomach.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—H. H. Munro: The Business of Engineering.

INSTITUTION OF ENGINEERING INSPECTION (at Royal Society of Arts), at 7.30.—C. H. Richardson: The Inspection of Ball Bearings.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—J. Sewell: The Commercial Aspects of Pictorial Photography.

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section) (Annual General Meeting and an Ordinary Meeting), at 8.30.—Dr. J. H. Chaldecott and others: Discussion on Coroners' Inquests: the Classification of Anæsthetic Deaths as violent or unnatural.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Dr. R. W. A. Salmond: A case illustrating the value of Pneumopericardium.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. W. J. S. Lockyer: The Growth of the Telescope.

RÖNTGEN SOCIETY

THE SILVANUS THOMPSON MEMORIAL LECTURE

The Sixth Annual SILVANUS THOMPSON MEMORIAL LECTURE will be delivered by

Mr. C. THURSTAN HOLLAND, D.L., Ch.M.,
Honorary Consulting Radiologist, Liverpool Royal Infirmary,

on TUESDAY, May 1, 1923, at

The Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2,

at 8.15 P.M. Entrance free to those who are interested.

UNIVERSITY OF LONDON.

A Course of Eight Lectures on "NUTRITION" will be given by Prof. V. H. MOTTRAM, M.A. (Professor of Physiology in the University), at KING'S COLLEGE FOR WOMEN, HOUSEHOLD AND SOCIAL SCIENCE DEPARTMENT (61 Campden Hill Road, W.8), on MONDAYS and WEDNESDAYS, April 30, May 2, 7, 9, 14, 16, 23, and 28, at 4.30 P.M. ADMISSION FREE, WITHOUT TICKET.

EDWIN DELLER, Academic Registrar.

UNIVERSITY OF LONDON.

The following Lectures have been arranged:

A Lecture on "PROBLEMS OF FUNDAMENTAL ASTRONOMY" by Professor W. DE SITTER (Professor of Astronomy in the University of Leiden) in the department of Physics, IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, Imperial Institute Road, South Kensington, S.W., on MONDAY, May 7, at 5.15 P.M. The Chair will be taken by the Astronomer-Royal (Sir FRANK DYSON, LL.D., F.R.S.).

A Lecture on "THE ELECTRIC CHARGE OF COLLOIDS" by Dr. H. R. KRUYT (Professor of Physical Chemistry in the University of Utrecht) in the department of Chemistry, UNIVERSITY COLLEGE, London (Gower Street, W.C.), on TUESDAY, May 8, at 5 P.M. The Chair will be taken by Professor F. G. DONNAN, C.B.E., F.R.S. (Professor of Chemistry in the University).

A Course of Three Lectures on "PHASES OF INDIAN GEOLOGY" by The Hon. Sir THOMAS H. HOLLAND, K.C.S.I., K.C.I.E., F.R.S. (Rector of the Imperial College of Science and Technology), at UNIVERSITY COLLEGE, London (Gower Street, W.C.), on WEDNESDAYS, May 9, 23, and 30, at 5.15 P.M. At the First Lecture the Chair will be taken by The Right Hon. Lord CHELMSFORD, G.C.M.G., G.C.S.I., G.C.I.E., G.B.E.

ADMISSION TO THE LECTURES IS FREE, WITHOUT TICKET.

EDWIN DELLER, Academic Registrar.

BEDFORD COLLEGE FOR WOMEN
(UNIVERSITY OF LONDON),
REGENT'S PARK, N.W.1.

Principal—Miss M. J. TUKE, M.A.

Degree Courses in Arts and Science. Course of Training in Social Work. For Resident and Day Students.

Easter Term begins THURSDAY, April 26, 1923.

AGRICULTURAL RESEARCH.

The MINISTRY OF AGRICULTURE AND FISHERIES is prepared to receive, not later than May 15 next, applications for grants in aid of scientific investigations bearing on agriculture to be carried out in England and Wales during the academic year commencing October 1, 1923. The conditions on which these grants are offered are set out on the prescribed form of application (A. 230/1), of which copies may be obtained from the SECRETARY, Ministry of Agriculture and Fisheries, Whitehall Place, S.W.1.

April 1923.

MUSEUM OF PRACTICAL GEOLOGY,
28 JERMYN STREET, LONDON, S.W.1.

The Museum is **closed** for repairs till further notice.

The offices and library of the Geological Survey are open to callers.

April 13, 1923. JOHN S. FLETT, Director.

TUITION BY CORRESPONDENCE

Rapid preparation by highly qualified tutors for

MATRICULATION,
Intermediate and Final B.A. and B.Sc.,
OXFORD AND CAMBRIDGE LOCALS.

Single subjects may be taken:—Latin, Greek, Hebrew, French, Mathematics, Chemistry, Logic, etc. For terms address—

Mr. J. CHARLESTON, B.A. (Hons. Oxon, & Lond.),
14 Elsham Road, Kensington, W.14.

UNIVERSITY OF LEEDS.
DEPARTMENT OF MATHEMATICS.

The Council will shortly proceed to the appointment of an ASSISTANT LECTURER in the DEPARTMENT OF MATHEMATICS. Duties to begin October 1. Salary £350 to £400 a year, in accordance with qualifications and experience. It is desirable, but not essential, that the selected candidate shall possess a competent knowledge of the higher portions of some branch of Applied Mathematics. Applications, stating academic career and subjects of special study, together with testimonials (one copy) and references, should reach the REGISTRAR, The University, Leeds, on or before April 27, 1923.

BEDFORD COLLEGE FOR WOMEN
(UNIVERSITY OF LONDON).

The Council of Bedford College invite applications for the posts of (i) DEMONSTRATOR in ORGANIC CHEMISTRY; (ii) DEMONSTRATOR in INORGANIC and PHYSICAL CHEMISTRY; (iii) PART-TIME ASSISTANT in LATIN.

Candidates must have an Honours Degree or its equivalent.

Applications must be received not later than Saturday, April 28.

For all particulars apply to the SECRETARY, Bedford College, Regent's Park, N.W.1.

INDUSTRIAL TRAINING AND TECHNICAL EDUCATION.

Appointment desired as DIRECTOR; fifteen years British, Continental, and Colonial experience. Fighting service with His Majesty's Forces, 1915-1919. Physically fit. Will proceed any part of Empire.

Address: "CEME," c/o NATURE.

N.B.—Transit letter and reply takes 40 days.

TO SCIENTISTS AND RESEARCH STUDENTS.
THE INTERNATIONAL BIBLIOGRAPHICAL SERVICE BUREAU,

employed by British Government Departments, University Professors, etc., supplies complete Continental and American bibliographies on any scientific, literary, or medical subject. Chemical work a speciality. Extracts made.

Headquarters: Vienna. English representative: "ALEXANDRIAN," 1A Longridge Road, Earl's Court, S.W.5.

WANTED to purchase set Geological

Magazine, also collection of geological and geographical books as nucleus of a University library. Teaching collections and apparatus also required. Professor L. DUDLEY STAMP, Killiecrankie, Sidcup, Kent.

FOR SALE—"Electrician," Vol. 42 to Vol 48

inclusive (Bound). "Journal of Institution of Electrical Engineers," Vol. 46 to Vol. 60 inclusive (Unbound).

Apply H. T., 4 York Mansions, Battersea Park, S.W.11.

STUDENT desires use of calculating machine

—anywhere in London. HITCHCOCK, 36 Adelaide Road, Brockley.

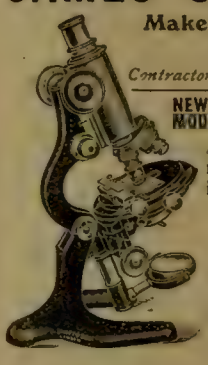
ACCURATE CHEMICAL THERMOMETERS.—

110° C., 150° C., 250° F., 300° F., 2s.; 200° C., 2s. 6d.; 360° C., 400° F. 3s.; 500° C., gasfilled, special glass, 10s. Beckmann's Thermometers with Auxiliary Scale, $\frac{1}{10}$° C., 22s. 6d. each. Approval.—CHEELD, Chesham.

WE SPECIALISE IN THE QUANTITY PRODUCTION OF OPTICAL AND MECHANICAL PARTS ON AN INTERCHANGEABLE BASIS. WE INVITE ENQUIRIES.

TAYLOR, TAYLOR & HOBSON LTD.,
74 NEWMAN STREET, LONDON, W.1.

JAMES SWIFT & SON LTD.



Makers of the highest grade Microscopes and Accessories.

Contractors to all Scientific Departments of H.M. Govt.

NEW MODEL **"UNIVERSAL" MICROSCOPE**

A perfectly designed Stand, with centring rotating mechanical stage, for Research in Pathology, Bacteriology, Haematology, etc.

For specifications and prices see list of new models, post free.

NO. 2790, VOL. 111]

Science and Government Administration.

SENSE, experience, humility, and imagination may teach one the need of advice: but some understanding of the subject is required to know whom to ask for advice and how to ask him; and still more to select advice, apply it, and act on it. In scientific matters this receptiveness of the recipient is an essential condition, otherwise the adviser is merely pouring water upon a flat plate; it bounces off, yet the plate shines and glories in its wetness.

In view of the supremely scientific character of modern war, can we say that the Army Council, Board of Admiralty, and Air Force Council possess the *sine qua non* for asking, selecting, applying, and acting on scientific advice in relation to the myriad problems of their occupation? These administrative bodies are called upon to foresee the wants of war and to make purchases and initiate researches for their fulfilment. They should, therefore, not only know what is wanted, but also understand what can be obtained. In the restricted sense of this use of the word "want" Julius Cæsar did not *want* electric light. He would have had to be even more remarkable than he was to want it, and then he could not have described the want effectively to any listener.

It is quite common for the lay public to be too unacquainted with what it can get to form a clear idea of its requirements—the man who tries to install central heating, or drains, without architect or builder will understand what is here meant. Luckily most people have sufficient knowledge of the subject and feeling of humility to determine them to go to the architect—that is because central heating and drains are everyday things. The lay public did not want railways—it did not know how to want them; it did not want automobiles until some years of education had been applied, and, coming nearer to our subject, the Army and Navy did not want aeroplanes until long after they were shown them. We are not making an accusation, but merely giving examples to show that the human faculty of wanting is a function of knowing what can be evolved, that is, education; and of imagining to what uses that provision can be extended, that is, vision.

There is the reciprocal of this also in "*not*-wanting." Ask any young officer at random if he wants the Finance Member of the Army Council; facetiously, but not without disclosing a true feeling, he will reply that "he has no use for him." With fairly precise analogy, if it were to be suggested to any member of the three councils named that a man of distinguished scientific attainments is wanted on these councils, he would with equal conviction, equal error, and possibly with equal facetiousness say, they "have no use for him" . . . "they have their advisers."

Suppose that there rises to the top at rare intervals a scientific admiral, "M.G.O.," or "Member for Supply and Research," it still remains the fact that in the absence of provision for securing by the law of the land that there *shall* be a man of wide scientific attainments on those councils, we cannot depend that, when a problem arises in council, its possible relation to science will be automatically and early considered. In many cases science will not be thought to touch the matter at all—and no attempt be made to get such advice. Unless there be some one, with full rights of membership, to probe into what can "per impossibile" be got from science, it is no comfort to know that there exist outside the Council advisers of great skill—since they would not be consulted—nay, they could not be consulted owing to the difficulty for the inexpert to pose the question even if he suspects the want.

A strong case can be made out for a scientific member of council—present at the fountain-head of war policy—at the place where the large problems arise, just as there is, at present, a finance member of council. The analogy of the finance member is apt because the public mind is far more financially sensitive and sane than scientifically acute and trained. Indeed, these councils themselves are almost certainly more awake to finance than they are to science. Is there not a House of Commons and a Press with money sense and taxation sensitiveness? But there is no similar power behind the scientific aspects of the case. It is not worth while to pose the false dilemma: which won the war, money or science? But it may be said that it is no use thinking the nation can safeguard its money if it does not safeguard its science. The awareness in money matters of the public due to its daily preoccupations, its annual state accountancy, etc., has ensured for money a representative at headquarters, but science has nothing of the kind.

No doubt the appeal of science would be better appreciated if it were expressed on terms of money. As an illustration of this the following episode is worth relating. The war council of a certain State was in session. A grave question had to be settled: advisers were outside the sacred chamber whence a member of council emerged, and, taking aside a man of science of European reputation who was in attendance and in the employ of that Army, propounded a question. As happens in such cases the inquiry sounded like: "How far is it from Somaliland to Good Friday?" so that the reply (and who has not gone through this ordeal!) began by hypothecating the alternative possible meanings and an inquiry as to which was intended. "I am not here to be interrogated but to be answered," was the reply inspired by a very proper fear of disclosing a clue to the secret policy in contemplation. The representative of science then gave an elementary lecture in which he reserved with dramatic instinct the essence of his reply for the climax. Before that was reached, however, the august member had excused himself and returned to his colleagues—fortified as a schoolboy would be for the reading of Plato by a knowledge of his subject limited to the alphabet. In the sequel some millions (not of marks) were expended on the scheme, which, however, was unfruitful.

Events and actions of this kind can be avoided only if the following principles are borne in mind:

(1) It is difficult even to ask for scientific advice so as to get it—unless the inquirer has scientific training.

(2) After asking for advice it cannot be taken without scientific training.

(3) When advice is taken it cannot be made effective without scientific training.

(4) However scientifically competent a man may be, he cannot advise on a case without knowing *à fond* how the problem arose and when, what qualifies it, and what alternatives might be employed to bye-pass the difficulty while still arriving at the goal.

It must be accepted that a genuine and thorough scientific training is not compatible with the multifarious changes of duty, changes of locality, changes of personnel, etc., essential to naval, military, and air force training. The development of a versatile, more or less uniformly trained force requires a *rota* of occupations by which officers and men, at stated periods of two or three years, are moved on to the various forms or classes which constitute the war school we call the Army, Navy, and Air Force. It is an accepted principle that no fighting man must become an indispensable expert; his loss would be too severe a discomfiture—his *ipse dixit* too formidable a threat to authority—his specialised training, and the unexpected bye-paths into which the laws of Nature would lead him, too incompatible with the whole principle of a versatile force of obedient and capable units united by a sedulously cultivated esprit de corps.

This is sound policy, and its acceptance leads to the conclusion that the scientific member of council cannot, any more than the finance member, be one of the routine organisation as we know it. We need scarcely plead here, after the War, that there is not, in a man of distinguished scientific attainments, any inherent unworthiness to be entrusted with State secrets. There is nothing peculiar about a suitably selected major-general that makes him a more acceptable recipient of such secrets than an equally well-chosen man of science. Nor yet is administrative ability incompatible with the widest range of scientific attainments.

The present-day divorce between the science which must infuse the war machine and the men who administer it is *not* of all time. Of old, as now, transport,

communications, weapons, archery, etc., involved a knowledge of man's endurance, food consumption, horses, shoe leather, the elastic qualities of yew, the flight path of arrows, and the like, but then, unlike to-day, every member of the governing staff was easily an adept in these matters, competent to select and profit by any expert specialisation—when for a spell generals commanded the fleet they were soon discovered not to be adept and the sea was entrusted to those who were. In both cases it was unnecessary to provide a seat on the council for the astrologer, alchemist, or magician of the time. To-day, however, all this is changed.

It is not to be expected that even a carefully chosen and widely informed scientific member of council can know ballistics, meteorology, chemistry, metallurgy, the thermodynamics of the petrol engine, the intricacies of sound detection, or of wireless procedures, the stability of ships, the phugoids of aeroplanes, the rotary derivatives of their equations of motion, etc.; but given a really sound scientific representative none of these subjects is to him what most of them are to the Army Council, Admiralty, and Air Force Council—at the best, jargon: at the worst, stupidity. Such a man would and could seek advice, because he knows enough of the problem and of the outlook of science to see that it was wanted. He could take advice because he would know enough to sift it, test it, select it, and present it for consideration to a council with the real purpose and personalities of which he would be acquainted.

How can we make such a need be felt by the war machine, which is certainly not asking our advice about it? Only by public opinion; and clearly this is difficult. Scientific opinion deserves better regard and esteem than it gets, and it suffers this loss because of the quite unreasonable contempt with which it views the operations of politicians. The world of science abstains from making its voice heard in the only way it can be heard, through the megaphone of the politician, by reason of the pressure of its organisation. It has itself no organisation. Some of the wiser men, who lifted their heads from the absorbing interest of their own grindstones, did in fact form a Conjoint Board of Scientific Societies, which died a month ago. This body comprised the leading Institutions and Societies in the British Isles concerned with pure and applied science. It might have leavened the lump, and reminded the technical world that it is an organic part of modern social organisation. Let us hope, as taxpayers, if from no higher motive, that science and technology may yet form a federation to promote recognition of their significance in the affairs of the State.

MERVYN O'GORMAN.

The Structure of the Atom.

The Theory of Spectra and Atomic Constitution: Three Essays. By Prof. Niels Bohr. Pp. x+126. (Cambridge: At the University Press, 1922.) 7*s.* 6*d.* net.

THE beautiful conception which inspires and co-ordinates practically the whole of modern atomic physics is the atomic model of Rutherford and Bohr. Its essential feature—the nucleus—was first put forward by Rutherford in 1911 on the basis of experiments on the scattering of α-particles. So convincing is this model that after only twelve years it is known no longer as "the atomic model of Rutherford and Bohr," but is simply taken for granted as "the atom." In this development, moreover, the ideas of Bohr have played such a dominating part that it is of the greatest importance that the three essays of this volume should be accessible in English, as well as in the original Danish and German, to the widest circle of readers. We welcome most heartily their opportune appearance.

When a theory such as the present is expounded semi-historically by its principal creator, a critical account of the theory itself is scarcely the function of a review. Such a critical discussion could be nothing less than an exhaustive survey of the whole tendencies of modern physics. It is perhaps a less impossible—certainly a more relevant—task to attempt to bring to notice the various stages of the theory represented by the three essays in this book, in the hope that some faint reflections of their beauty and convincingness may be conveyed to those whose studies are directed elsewhere.

Some preliminary remarks of a general nature may not be out of place. Though the theory itself finds a place for much advanced mathematical analysis and demands the development of new and more powerful weapons than those yet available, in the hands of Bohr it is never an abstraction divorced from contact with physical realities. Rather he succeeds in bringing it ever into closer contact, and expounds it in these essays in a simple non-mathematical way which should be capable of being followed by any one who is prepared to accept the mathematical theorems on which the work is necessarily based. The mathematician will desire to look further into the foundations and will be rewarded. But those who are not mathematicians need not for that reason fall short of full conviction. It is unavoidable to speak of the theory, in description or exposition, as "explaining" certain facts of experience. But the theory is non-mechanical—in fact, is nowadays identical with the quantum theory—and "explanation" by the theory cannot mean explanation in the classical sense. Explanation of a fact can mean no more than its correlation with and co-ordination among an existing

body of other facts which can all be similarly related to the same general principles; this, however, is enough. Beyond this we can ask for nothing less than a reformulation of the whole principles of physics, which shall present both classical mechanics and electromechanics and the quantum theory as parts of a homogeneous whole. So far the divergencies between the two theories have become, if anything, rather more than less fundamental and mysterious, but the points of contact between the two theories, embodied mainly in Bohr's correspondence principle, have become ever more numerous and more sure. They are linked in a way which compels regard for them as two aspects of the same reality. It is the range and power of the correspondence principle, emphasising all these resemblances, which gives the theory its overwhelming appeal.

It is unnecessary to dwell on the first essay—"On the Spectrum of Hydrogen" (December 1913)—which presents, in a way now generally familiar, the suggestive but *ad hoc* arguments by which Bohr started the theory with such a combination of the ideas of Planck and Rutherford as to explain the spectra of the atoms of hydrogen and ionised helium and to promise an interpretation of the general laws of spectra. We pass to the second, "On the Series Spectra of the Elements" (April 1920), which breaks fresher ground. During 1913–1920 the theory had developed rapidly in its applications to subsidiary features of the hydrogen spectrum, which, besides Bohr and others, Sommerfeld, Schwartzschild, Epstein, and Debye took part in working out. It was extended to account with complete success for the fine structure of the hydrogen lines, and the effect thereon of external electric or magnetic fields. These advances can be summarised by saying that the way had been discovered for applying the quantum theory to a certain class of atomic systems of any number of degrees of freedom. This class is technically known as the class of quasi-periodic systems which permit of separation of the variables. Meanwhile Bohr put forward his correspondence principle, of which the germ is already present in the first essay, and the principle of mechanical transformability which he derived from Ehrenfest; principles which knit the foregoing results into a co-ordinated whole.

Briefly, the correspondence principle is this. If we expand the motion of a system in a series of sines and cosines of the time, a multiple Fourier series, in the complete radiation of the system demanded by classical theory a component of definite frequency, a definite "combination tone," will correspond to each term in the expansion. The correspondence principle asserts that there is a fundamental connexion between each "combination tone" and the possible switches from orbit to orbit, or changes of quantum number, which, on the quantum theory, give rise to radiation. In the limiting case of large quantum numbers there must be full agreement not only in frequencies but also in polarisations and intensities. This presents a rational means for extending the correspondence to all quantum numbers; every switch "corresponds" to a definite harmonic constituent in the mechanical motion of the atom. If any particular constituent is absent not only from the motion in the initial and final states but also from the whole family of mechanically possible motions, which are not themselves permitted orbits or stationary states but form a continuous transition between the initial and final states, then the corresponding switch will never occur. The complete success of this principle in accounting for details of the hydrogen spectrum is well known. A successful beginning has even been made by Kramers in the study by its means of relative intensities.

This, however, is only part of the ground covered by the second essay, which also applies these ideas to other spectra, in particular those of helium and the alkali metals. These sections must be read with Parts II. and III. of the third essay, which make important corrections. First, the assumptions of stationary states and the fundamental relation $E=h\nu$ between energy and frequency (first essay) explain naturally the combination principle of Ritz, for Ritz's "terms," the combinations of which are spectral lines, have now a physical meaning as the energies of the atom in its various stationary states. Consider a concrete example —sodium—with nuclear charge 11 and 11 planetary electrons. The inert properties of neon (10) indicate that we must suppose that the first ten electrons form together a very stable structure into which no further electron can be taken up on the same footing.

To a first approximation then, from the point of view of the eleventh electron, the effect of the first ten will simply be to modify the field in which it moves, so that, while its central symmetry is approximately preserved, the effective nuclear charge is a function of the distance from the nucleus, which is 11 at short distances and 1 at large. The same arguments hold for other alkali metals. If the exact law of variation of effective nuclear charge were known (numerically), the energies of all possible stationary states of the single external electron could be computed. We must, in any case, find that the set of stationary states forms no longer (as with hydrogen) a single series of terms depending on an integer n, but a double series depending on two integers n and k. We find that with absolute confidence we can identify the sharp terms with those for which $k=1$, principal terms $k=2$, diffuse terms $k=3$, and Bergmann (fundamental) terms $k=4$. Moreover, on the correspondence principle,

only those combinations of terms will normally give rise to lines for which k changes by ± 1. This is precisely what is found to occur, and the puzzling incompleteness of Ritz's combination principle is entirely accounted for. There is, moreover, no real element of arbitrariness in this explanation, for the variation of the effective nuclear charge is of course due to the already bound electrons. These must lie in permitted orbits of definite quantum numbers which fit in with those of the spectral terms for an approximately central field of force, not very greatly modified from that which acts on the last electron. The numerical requirements of the theory can be satisfactorily met, and there remains no doubt that the atom must be regarded as fitting together in some such way. Perhaps this paragraph somewhat overstates the completeness of the theory as here expounded by Bohr, but it does not, I think, misrepresent it.

Besides its main contribution, the second essay also touches on and exhibits in their proper perspective other spectral facts—the spectra of ionised atoms, in particular those of the alkaline earths, with their Rydberg constant $4N$, which results naturally from the double residual charge with which the ionised atom controls its last electron; doublet and triplet separations, which arise from the deviation of the atomic field from central symmetry leading to the introduction of a third quantum number; finally, the unique nature of the helium spectrum with its absence of inter-combinations, of which an explanation in terms of a further generalisation of the correspondence principle may at least be said to be in sight.

These are mainly facts of which the explanation is still under development, but three further complete successes of the theory must also be recorded. The idea of stationary states accounts completely for the differences between emission and normal absorption spectra. An atom in its normal state can absorb only those lines for which the normal state is the initial stationary state of the absorption switch. For an alkali metal this means the principal series of doublets only—for an alkaline earth the principal series of singlets. In other cases, such as the aluminium subgroup, the theory leads us to expect that the normal state will correspond to the first principal term and that the absorption spectrum will be the sharp and diffuse series—an expectation recently confirmed by direct experiment. Secondly, the phenomena of resonance spectra are fully accounted for. Thirdly, the theory assigns definite energies to the various atomic states, and this assignment can be tested directly by the study of electronic impacts. This is by itself a complete branch of modern physics directly inspired by the theory, which it as directly and completely confirms.

The third essay, "The Structure of the Atom and the Physical and Chemical Properties of the Elements" (October 1921), is the most novel and important of the three. It differs from the others in being slightly revised in translation to bring it up-to-date (May 1922). This essay brings the whole of the available evidence—X-ray, chemical, optical—to bear on the specific question of the structure of the atom; that is, the way in which the planetary electrons are arranged. We have already seen that this is implicitly discussed, and a definite view reached, in connexion with the theory of series spectra. Other evidence merely confirms and crystallises this view. The goal to be attained is the theoretical deduction, from the principles of the quantum theory properly formulated, of the periodic table of the chemical elements, and all other atomic properties. Bohr shows that the fundamental process which must be considered is the successive binding of electrons one after another by a nucleus originally naked, and that, if we could say what would be the final orbit of the nth electron bound by a nucleus of charge Z, we could deduce the general features of the periodic table and other atomic properties in the desired manner. He shows that already we know, partly theoretically, partly empirically, a very great deal about these binding processes. The arguments cannot usefully be summarised. The result is that we can specify with considerable certainty the two principal quantum numbers, n and k, of the orbits in most atoms. The orbits thus fall into a number of groups, and we know the number of equivalent orbits in each group. The groups of orbits are arranged with various types of spatial symmetry; they must on no account be thought of, as in earlier models, as forming coplanar rings of electrons. The systematic study of X-ray levels begun by Kossel in the field opened up by Moseley has played a leading part in this development.

There are two crucial points to be emphasised in the present position of the theory, which can best be stated as questions. *Can we deduce from the quantum theory the particular points at which a group of electronic orbits fills and a new group starts?* In particular, can we prove that the third electron in the lithium atom must remain in a new type of orbit ($n=2$, $k=1$) and not fall into an orbit equivalent to those of the first two electrons ($n=1$, $k=1$)? Secondly, *can we deduce from the theory the regular sequences of physical and chemical properties, together with their occasional interruption for groups of homologous elements such as the iron group or the rare earths?* It can scarcely be said, and Bohr, I think, does not claim that an unqualified "yes" is yet the answer to the first question; but putting the question is itself a great advance, and the lines on which an answer will be forthcoming are already clear. It seems certain

that the impossibility of the third electron getting into a 1-quantum orbit is of the same nature as the impossibility of intercombinations in the helium spectrum or of the two coplanar electrons of the orthohelium spectrum getting both into coplanar 1-quantum orbits. These impossibilities seem to be connected with the absence of any coherent class of mechanically possible orbits which continuously connect together the initial with the desired final state, but the absence of such classes is scarcely yet established.

Granted the answer "yes" to the first question, the answer "yes" in general terms can now be given fairly to the second, though of course only a fraction of the interesting points of detail have yet been worked out. It can already be stated definitely that, for example, the iron group accompanies the establishment of orbits of type ($n=3$, $k=3$) in the normal atom which (it is almost a direct deduction) appear for the first time at scandium. They occur in the fourth period and differentiate it from the second and third because there for the first time is it arithmetically possible for successive atoms to differ by an extra electron in an inner orbit instead of in an external one. In the same way the rare earth group is associated with the development of orbits of the type ($n=4$, $k=4$), the outer orbits consisting of both 5-quantum and 6-quantum orbits, the same in number and much the same in form from atom to atom.

It is a great theory and a great work. Its most fruitful stages are yet to come.

R. H. FOWLER.

Religion and Evolution.

The Religion of Science. By Prof. William Hamilton Wood. Pp. xi+176. (London: Macmillan and Co., Ltd., n.d.) 6s. net.

AT the present time it is especially interesting to compare the way in which, in different parts of the world, thoughtful men regard the relation between religion and science. We should expect to find a general uniformity in the different attitudes of representative thinkers in Great Britain and America. We are largely of the same stock. We speak substantially the same language, so that books in large numbers pass in both directions across the Atlantic. But it is a curious fact that the popular religious dislike of evolution, which even enters into politics in the Middle Western States, affects leaders of American thought. No theologian of eminence in England would now challenge a scientific conclusion, for which experts combine to demand our assent. Yet, in the book before us, the professor of biblical history and literature in a college at Hanover, N.H., makes a vigorous attack on "the religion of science," and argues that man cannot be fitted into the scheme of biological evolution. *No fossil or organic half-man*, says the professor in impressive italics, *has ever been discovered, and never will be.* (Grammatically the final clause means the opposite of what the professor intends; but we will let that pass.)

Most readers of NATURE will be tempted to say at this stage, "The man's a crank. No need to read further." But the judgment would be unjust. Prof. Wood, though his literary style is at times painful, has clearly given close thought to the problems which he discusses. As against certain views expressed by American writers, in works with which we are unfamiliar, he argues acutely. He shrewdly exposes the illegitimate metaphysical assumptions of the "science-theology," which we should agree with him in condemning. But he has not apprehended the larger synthesis generally accepted by English theologians. Because his outlook is too limited, the theory of evolution seems to him to eliminate "God as a real existence and personality." So to preserve religion he rejects evolution.

This apparent necessity could not arise were there not a latent dualism in his thought. Christian theology in the third century took over from Neoplatonism a belief in the unity and solidarity of the universe. This belief, of course, is in fundamental harmony with the teaching of Christ. Failure to preserve it intact in all its implications is the source of most of the difficulties which have troubled Christian divines in their warfare with "science-theology." Prof. Wood is really following a degenerate tradition when he opposes the "natural" to the "supernatural" instead of pleading that in all Nature spiritual activity is manifest. His dualism causes him to speak of, "on one side, the non-moral development of the universe which is continuous, while within this, or related to it, is the moral evolution terminating in man." He can also say, "The main point is not whether mankind came originally from a single pair or was spawned like larvæ, nor is it our simian ancestry. It is that man is a derived and, therefore, secondary product." We need not comment on the biological character of the first sentence; but we would ask, Why should the derived product of the harmonious working of a universe, informed by Spirit, be secondary? Surely we should expect the creative activity of Spirit to work towards something of which it is the archetype; or, in more familiar language, that God has, by the slow process of evolution, created man for communion with Himself.

Prof. Wood does not see that, if Christian thinkers can justify their belief that the whole world arose and took its pattern because of the creative activity of Spirit, they need not quarrel with evolution. On the

contrary, the biological doctrine then becomes a description of the way in which Spirit has worked; and, by interpreting it, we get an understanding of the nature of spiritual reality. By tacitly opposing Nature and Spirit the professor finds it difficult to resist the conclusion that "the original and primal is the real." But if we are convinced that the process "from nebula to man" reveals Spirit working in time, we shall see, in Nature, degrees of reality which have successively emerged, the last being the consciousness of civilised man.

How can we meet the contention that there is no such reality as Spirit? We answer that the fundamental objection to the naturalism, which Prof. Wood terms science-theology, is that it is inconsistent with itself. It makes spiritual judgments while denying spiritual reality. Science, within its proper sphere, is quantitative. In it the mind abstracts those aspects of Nature which can be measured. But then the mind forms scientific concepts "in which the phenomena given in perception attain to a higher degree of coherence and of truth." We prize these concepts because of their truth-value. But value-judgments belong to the world of spirit, to a kind of existence to which merely numerical categories do not apply. To the same spiritual world such qualities as justice and virtue belong. Strictly speaking, they lie outside the realm of natural science. Men of science are always, often unconsciously, interpreting their results by means of value-judgments. Such a phrase as "the survival of the fittest" is a well-known example of this process. For the explanation of a thing or an event we have to use what is above it in the scales of existence or value. Yet, in spite of this, men of science who are constantly studying properties of matter, living or dead, jump to the metaphysical conclusion that matter is ultimate reality. The legitimate conclusion is rather that ultimate reality is spiritual, and that goodness and beauty, like truth, reveal its nature.

The relation of matter to spirit continues to perplex us. But the tendency of modern physics is increasingly to reduce matter to a mere metaphysical abstraction, like the ether, which is the subject of energy. Some physicists appear to regard matter as nothing but a form of energy. But neither view will allow us to regard the universe as a self-acting machine, for in such a conception mind can have no place. Moreover, as soon as natural science ceases to be merely descriptive, the idea of causation enters in. We cannot explain cause unless we admit creative action working towards a definite end, so that the laws of Nature express the uniform mode of action of a Supreme Will. The doctrine of evolution indicates the purpose of that Will, for it asserts that earth's life-process has led to man, whose conscience tells him that he must be loyal to absolute values external to himself. God, in short, reveals His own nature in the highest faculties of humanity.

It cannot, we think, be fairly argued that belief in evolution destroys the Christian hope of eternal life. That hope rests ultimately upon belief in "the conservation of values," upon a conviction that the attributes of God are eternal with Him. We now know enough of the universe to be sure that within a measurable period life upon this earth will come to an end. All humanity's spiritual achievements will then perish unless there is a Kingdom of Heaven where they are eternally preserved. Among such achievements the perfecting of personality ranks highest. It is difficult to conceive either of timeless existence or of a perfect human soul; but the reasonableness of our hope of eternal life is not thereby destroyed. Significantly Christianity connects belief in human immortality with its doctrine of the Incarnation, its affirmation that, in a perfect Man, God has actually been revealed.

We can do no more than hint at our reasons for disagreeing with Prof. Wood's point of view. But, because we have criticised his views, we would commend his honesty, his freedom from bigotry, and the high seriousness of his aim. The problems which have engaged his attention are as difficult as they are vital. It is probable that humanity will never solve them completely; it is certain that now we can but see "as in a glass darkly." E. W. BARNES.

A Peruvian Desert.

Geology of the Tertiary and Quaternary Periods in the North-west Part of Peru. By Dr. T. O. Bosworth. With an Account of the Palæontology by H. Woods, Dr. T. W. Vaughan, Dr. J. A. Cushman, and others. Pp. xxii+434. (London: Macmillan and Co., Ltd., 1922.) 2*l.* 5*s.* net.

THERE are few contributions to geological science, published in recent years, of greater value than this description of some three thousand square miles of the littoral of northern Peru.

Dr. Bosworth, who was formerly in the British Geological Survey, was still a young man when he left it to take up economic work, but he had already made himself a name for sound and original geological research. The present publication is not the result of a rapid traverse of the area with which it deals, but is the fruit of several years of exploration, reinforced by detailed surveys in many places and numerous borings for oil, in which the characters of the strata traversed were carefully observed. Dr. Bosworth has

had one great advantage; the desert conditions that prevail expose clearly to view much more of the characters and structures of the rocks than meets the eye in more fertile regions. At the same time, he has spared no pains to make his work as complete as possible. In order that the fossils collected should be properly described he has enlisted the services of a number of the leading palæontologists in this country and America, and their descriptions, figures, and conclusions are given in full.

The district described rarely exceeds a thousand feet in height above sea-level. It lies between the Pacific and a background of the Western Andes, which consist of pre-Tertiary rocks folded under the stresses of the zone of compression that encircles the greatest

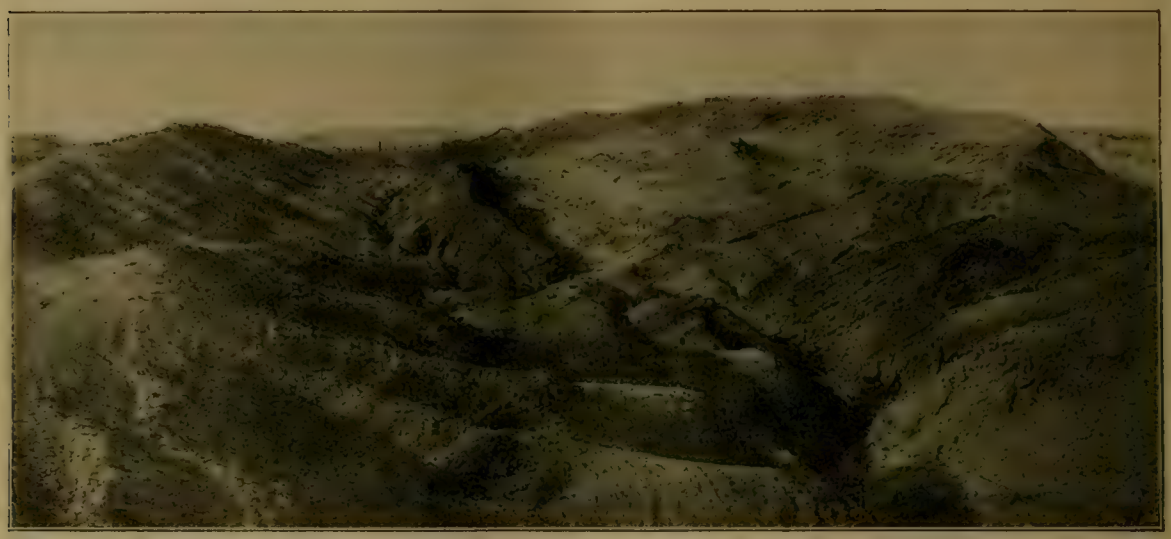

FIG. 1.—Ridge-and-furrow topography, produced where the strike of the beds is in the same direction as the prevalent wind. From "Geology of the Tertiary and Quaternary Periods in the North-west Part of Peru."

of our oceans. The latest strata involved in the folds are of Cretaceous age, and it must have been after their deposition that these mountains were raised up and exposed to the destructive activities of sun, wind, and running water, and in all probability frost and ice as well. From the debris a great succession of sedimentary strata of Tertiary age were accumulated to a thickness of some 20,000 feet on the slowly subsiding ocean floor, not without important breaks in the succession, for only the Eocene and Miocene are represented.

The denudation of the mountains and the accumulation of the sediments over a broad tract on the margin of the Pacific appear to have destroyed the isostatic balance that had previously existed and created a state of strain which finally resulted in a great fracture off the coast, the western side being thrown down deep below the surface of the sea, and the eastern, which included such of the Tertiary deposits as were in the immediate neighbourhood of the shore, raised above its previous level. It was at the same time broken up into numerous blocks separated by minor faults, often of considerable throw, constituting a kind of fault breccia on a gigantic scale.

In this aggregate of dislocated sediments the action of the sea, assisted by subaerial agencies, excavated a broad, nearly horizontal shelf, which reached to the foot of the mountains, and became submerged sufficiently to allow of a new series of deposits being laid down upon it, which must be referred to the Quaternary Period, as they contain remains of forms identical with those living in the adjoining sea. Then a period of elevation supervened, and the former sea-floor was exposed to view as a nearly level plateau—a *tablazo*, as it is called locally—and it still remains in many places almost in the same condition as it was when the sea left it. Its western margin was now attacked by the waves and a second shelf was carved out, which was covered by another series of deposits, and afterwards raised to form a second *tablazo*. Still another *tablazo*, possibly more, would seem to have come into existence in the same manner. The last tracts to be raised from the sea were the *salina* or salt plains, which are scarcely above the reach of the spring tide. Indeed, some parts are occasionally submerged. Remains attributed to the Incas are found upon them, and some of the land a few hundred yards from the high-water line has been irrigated, apparently by them. It would seem therefore that there can have been no appreciable change of level since the coming of the Spaniards. The author infers that not a ten-thousandth part of the Quaternary history can have elapsed in the last five hundred years. This would give Quatern-

ary time a duration of at least five million years, which seems an over-estimate. In all probability the rise of the land has not been continuous, but rapid movements of elevation have alternated with long ages of quiescence, while the occasional periods of submergence may be explained by a slow continuous rise of the ocean level, such as is believed by Daly to have taken place in the Pacific. It is worthy of note that there appears to be no evidence of any renewal of compression since that to which the mountains owed their formation in late Cretaceous or early Eocene times. This suggests a doubt as to whether the westward movement of South America, postulated by Wegener, can have continued far into Tertiary times.

Fig. 2.—"*Rabo de Leon*" growing among blocks of quartzite in the Amotape Mountains. (The height of these plants here is about 3 feet.) From "Geology of the Tertiary and Quaternary Periods in the North-west Part of Peru."

There is not space to follow the author in his description of the climatic conditions in the desert; of the effects of the rare torrential rains and the slow desiccation that succeeds; of the deeply cut valleys, the breccia fans, and the valley and marine terraces; of the work of sun and wind, and of the scanty animal and vegetable life; except to say that the book should take its place beside the writings of Walther and Cloos in the libraries of all students of the desert.

The concluding chapters contain a useful account of the petroleum deposits of the area, in which oil-wells have been sunk to a depth of 4000 feet. Valuable information is afforded as to the stratigraphical range of the oil, and the history of its exploitation is described; but it is unfortunate that in deference to the wishes of the International Petroleum Company no detailed account of the main oil-field is given. "With the exception of a few general comments, sanctioned by the Company, the development and conclusions of the past eight years are excluded from this description." Considering how much the great industrial organisations owe to science, one would expect from them a little generosity, even a little sacrifice of material advantage, if such be required, that they may repay their debt to research by adding their quota to the general fund of human knowledge.

It only remains to state that the book is excellently illustrated by numerous sketches and reproductions of photographs (two of which are given here) and by clearly-drawn maps, plans, and sections.

John W. Evans.

Our Bookshelf.

Aspects of Science. By J. W. N. Sullivan. Pp. 191. (London: R. Cobden-Sanderson, 1923.) 6*s.* net.

Most works on that department of thought which lies on the frontier between philosophy and science should be included by pharmacologists among the class of narcotic drugs. As narcotics they are very effective, for they induce oblivion rapidly and profoundly, and they have the great advantage of being without any of the undesirable—or other—after-effects that are

common with such drugs. Notably, they have not the great drawback of most narcotics of inducing a craving for the constant repetition of the dose. Perhaps this character is partly determined by the circumstances in which these works are mostly used. Observation will confirm the general impression that such books are largely resorted to by elderly men of science, after working-hours, in the fastnesses of club libraries or by the domestic fireside. Mr. Sullivan's book is, however, useless for such purposes, for he defies slumber!

We do not remember to have read in English anything on the philosophical implications of science comparable to this little book for its wit. Easy writing is said to make hard reading, and, if the converse is true, an immense amount of labour must have been thrown into this series of very short chapters. Short though they are, many of them leave a feeling of remarkable completeness, and some of them, such as those on "Assumptions in Science" and "The Sceptic and the Spirits," are really little masterpieces in which we feel Mr. Sullivan has said the last word in the present state of knowledge.

There are many books on the nature of science and on its philosophical and ethical relationships, but there are very few that will appeal to younger people. Mr. Sullivan has, however, produced such a work. It can be safely placed in the hands of any student; most of it can be understood by any intelligent boy or girl of the age of sixteen; it is always challenging without ever being dogmatic, and witty without ever being cruel or "cheap." Any scientific man with the slightest philosophical bent must find this work stimulating and refreshing, and it is obviously written by one with a remarkably wide working knowledge of science.

C. S.

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Prof. Dr. Emil Abderhalden. Abt. IX: Methoden zur Erforschung der Leistungen der tierischen Organismus. Teil 4, Heft 1: Methoden der Erforschung bestimmter Funktionen bei einzelnen Tierarten. Lieferung 76. Pp. 122. (Berlin und Wien: Urban und Schwarzenberg, 1922.) Grundzahl: 4·8 marks.

THE new section of Abderhalden's invaluable "Handbuch der biologischen Arbeitsmethoden" contains a very useful résumé of methods for the study of digestive secretions in the lower forms, an account of the technique of gonadectomy and transplantation of germinal tissue in insects, together with a rather longer review of experimental procedure in the study of pigmentary responses. This section, by Dürken, suffers, like the author's recent "Einführung in die Experimentalzoologie" (1919), from a complete disregard of the large volume of experimental work on amphibian metamorphosis and the illuminating observations on colour response which have emerged from it during the past eight years; consequently it deals exclusively with methods for studying factors which induce pigmentary responses rather than the mechanism which co-ordinates them. Perhaps it is inevitable that such omissions should occur owing to the economic handicaps under which scientific workers are pursuing their labours in Central Europe at the present time. Still, it is difficult to believe that the author of the "Methoden zum Studium des Pigmentwechsels" had no opportunities of consulting the extremely important work of Spaeth, Redfield, Smith, Allen, Laurens, and Swingle, none of whom is mentioned in his survey, though there have been since 1918 few numbers of the *Journal of Experimental Zoology* which do not contain some contribution to the physiology of pigment response in amphibia, reptiles, or fishes.

Infant Mortality. By Dr. Hugh T. Ashby. Second edition. (Cambridge Public Health Series.) Pp. xii+224. (Cambridge: At the University Press, 1922.) 15*s.* net.

BY "infant mortality" is meant the ratio which the number of infants who die in any one year bears to the number of births in that year. The rate for the country generally remained more or less stationary until 1905, since when, however, it has steadily decreased, so that during the last two or three years it has been only about half that which obtained in the late nineties of last century. Infant mortality is of enormous national importance, for with the present low death-rate, which it will be difficult in the future materially to reduce, and a falling birth-rate, now only about two-thirds what it was at the end of last century, the maintenance of our population will largely depend upon the survival of as large a proportion as possible of the infants born.

The appearance of a second edition of Ashby's "Infant Mortality" is therefore opportune. The practical side of the question has been kept in view throughout, and purely medical technicalities have been omitted. The condition is a very complex one, but an attempt is made to ascertain its main causes; one of these, summer diarrhœa, has been practically suppressed. The number of still-births and the mortality during the first week of life are still far too high, and their causes merit further investigation. Maternal mortality shows an actual increase of late, and needs to be taken seriously in hand.

The author has skilfully marshalled his facts, and the chapter on the means by which infant mortality may be further reduced gives an excellent summary of the subject.

Pests of the Garden and Orchard. By Ray Palmer and W. Percival Westell. Pp. 413+47 plates. (London: Henry J. Drane, Farringdon Street, n.d.) 25*s.* net.

IN the work under notice the authors have aimed at meeting the needs of practical agriculturists and horticulturists by collecting into one book all the available information on plant pests and diseases necessary for their guidance. Insects and other animals, fungus diseases and weeds, are all dealt with categorically under their separate headings, a short description and the methods of treatment being given in each case. Many of the numerous illustrations are very clear, but others are scarcely sharp enough to prove efficient aids to identification.

Among other useful features special attention may be directed to the detailed formulæ for sprays, with antidotes to the various poisons used in their composition, and also to the identification and spraying tables for insect pests and plant diseases. For identification

these are classified under the heading of the plant attacked, and the chief features of each are indicated with reference to the further descriptions in the text, whereas the spraying tables summarise the applicable methods of treatment with instructions as to the time they should be carried out. Altogether the practical man, and others, will find this a most useful handbook for obtaining much of the necessary information that is otherwise very scattered.

Business Geography. By Ellsworth Huntington and Prof. F. E. Williams. With the co-operation of Prof. R. M. Brown and Lenox E. Chase. Pp. x+482. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1922.) 13*s.* 6*d.* net.

THE authors intend this volume to be used after a course on commercial and industrial geography. It deals with the principles of geography, the effect of specific geographical factors, types of human communities, and the trade and commerce of the continents, with more detailed consideration of the United States. The book is a welcome addition to the volumes already available on the geography of production and commerce, and in its width of outlook and wealth of ideas should prove very stimulating, and occasionally provocative, to all readers. In one essential respect it differs from most books on the subject: the human factor in business relations receives ample consideration. The world is treated not merely as so many places, each producing so many products: the varying physical and mental qualities of races are recognised and given their due weight in the explanation of the development of the world. Stress is also laid on the relation of man to different climates in respect of wealth and efficiency. The book is admirably illustrated, and there are a number of ingenious exercises attached to each chapter. It is a book that should find wide acceptance in spite of its unattractive title.

Practical Colour Photography. By E. J. Wall. Pp. vii+248. (Boston, Mass.: American Photographic Publishing Co.; London: H. Greenwood and Co., Ltd., 1922.) 13*s.* 3*d.*

THE representation of colour, in addition to form and light and shade, by photographic means is a subject that has been allowed to get very far behindhand so far as text-books of photography are concerned. Mr. Wall's volume is therefore very welcome as doing a great deal towards filling this gap in photographic literature, which has been automatically increasing for many years. It does not quite fill the gap, for photo-mechanical methods are not treated of, historical and theoretical data have been, so far as possible, omitted, and the scope of the work has been restricted by the fact that all methods and formulæ given have been personally tested in practice. But within the limits indicated it is surprising how many methods there are of representing colour. Of three-colour processes there are the carbon and gum bichromate processes, the imbibition of dyes, mordanting processes, the bleach-out process, and the use of screen plates (autochrome, Paget). Of what may be called direct processes there are the interference heliochromy of Lippmann, the use of "silver subchlorides," and the diffraction and prismatic dispersion processes. Finally there are two-colour processes, and those adapted specially for cinematography. The book forms an excellent practical introduction to the subject.

Le Négatif en photographie. Par A. Seyewetz. Deuxième édition, revue, corrigée et augmentée. (Encyclopédie scientifique: Bibliothèque de Photographie.) Pp. viii+308. (Paris: Gaston Doin, 1923.) 15·40 francs.

M. SEYEWETZ is chiefly known to us by the researches that he has carried out, often in conjunction with M. M. Lumière. One naturally expects an author to treat more fully of those subjects that he has personally studied. In the present case this is a distinct recommendation, for the author's investigations have been so largely connected with the processes involved in negative making. The summaries of the characters, use, and effects of the various developing agents are especially valuable. It is of interest to notice that M. Seyewetz is not one of those who believe that development is a mechanical process which cannot be varied except to the detriment of the negative. The paper and the quality of the illustrations of this volume show that our neighbours have not recovered so far as we have in this country from the detrimental effects of the War, but these matters do not detract from the sterling character of the volume.

Practical Handbook on the Diseases of Children: For the Use of Practitioners and Senior Students. By Dr. Bernard Myers. (Lewis's Practical Series.) Pp. xvi+548. (London: H. K. Lewis and Co., Ltd., 1922.) 21*s.* net.

THE important subject of diseases of children is one which is too often neglected in the curriculum of the medical student. Dr. Bernard Myers has produced a handbook in which he has treated the subject mainly from the practical side. He has adopted the usual arrangement of considering anatomy and physiology first, then clinical investigations and the diseases of the various systems. Articles have been contributed by experts in their special branches, *e.g.* biochemistry, serum therapy, physiology of digestion, and syphilis. Some confusion may arise from the separation of nutritional disturbances from affections of the stomach and intestine, and also from the classification of nutritional disturbances as "failure to gain," "dyspepsia," "decomposition," and "intoxication."

The moderate size of the book, its concise descriptions and practical aspect, combine to make it a useful addition to the student's text-books and the practitioner's library.

Religion and Biology. By Ernest E. Unwin. (Christian Revolution Series, No. 15, Pp. 185.) (London: The Swarthmore Press, Ltd.; New York: George H. Doran Co., 1922.) 6*s.* net.

THIS work, written from the point of view of a member of the Society of Friends, is an attempt to outline the biological approach to questions of religious thought, and should be of use to school teachers. The author believes he has a message for biologist and schoolmasters. His gentle and spiritual point of view never raises opposition, and the book will be found of value for the purpose for which it is designed.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Crystal Structure of Basic Beryllium Acetate.

PROF. G. T. MORGAN recently sent me some well-formed crystals of basic beryllium acetate $Be_4O(C_2H_3O_2)_6$, suggesting that their analysis by X-ray methods would, in all probability, be of considerable interest. The results show, I think, that the anticipation was well founded.

The molecule is a perfect tetrahedron. The crystal structure is that of diamond, a molecule replacing each atom of carbon. The carbon atom is itself tetrahedral, but is very nearly a sphere. The slight departure from sphericity is shown by the presence of a very small second order in the reflection by the tetrahedral plane of diamond. In the acetate this effect is large, because the tetrahedral character is so much more pronounced than in the carbon atom.

The oxygen atom must be at the centre of the tetrahedron. The beryllium atoms lie on the lines from the centre to the corners; and each $(C_2H_3O_2)$ group must be associated in a very symmetrical manner with one of the tetrahedron edges.

Prof. Morgan and I hope to give, at a later date, a fuller description of the analysis, and to discuss the inferences that may be drawn from it.

W. H. BRAGG.

A Theory of the Viscosity of Liquids.

As is well known, the viscosity of gases and its variation with temperature has received a satisfactory explanation on the basis of molecular theory. Little progress has, however, been made towards explaining the phenomena of the viscosity of *condensed* media—that is, of liquids and solids from a molecular point of view. What is evidently required is a working hypothesis which will indicate why, when a substance passes from the state of vapour to that of liquid, its absolute viscosity is greatly increased but *diminishes* with rising temperature, while that of the vapour *increases* in the same circumstances. I propose in this note to put forward briefly the outline of a theory which appears to have claims to serious consideration, as it indicates a quantitative relation between the viscosity of a liquid and of the corresponding vapour which is supported by the experimental data.

The manner in which transverse stress is propagated through a material medium is known in the cases in which the substance is in the state of vapour and in that of a crystalline solid. In the former case, momentum is transferred through the diffusion of the molecules between parts of the medium in relative motion, and this is a relatively slow process. In the crystal, on the other hand, the stress is transmitted in the form of transverse elastic waves, and the latter process, at least for ordinary displacements, is extremely rapid. We may conceive that in a liquid, momentum is transported partly by the first process and partly by the second, and that the effective viscosity depends on their relative importance. The ratio in which the two modes of propagation are operative may be determined from thermodynamical considerations, combined with certain simple suppositions regarding the constitution of a liquid.

We shall assume that the state of aggregation of the molecules in a liquid is of a composite character: some of the molecules are quite free to move, and may be termed "vapour" molecules; the others are attached to each other somewhat as in a crystal, and may be termed "crystalline" molecules. In determining the proportion of the two types, we shall consider only binary encounters between molecules. Let E_1 be the work required to separate a pair of molecules of the first type, and E_2 those of the second type. Then applying Boltzmann's distribution law, we may, as a first approximation, take the relative proportion of the two types of aggregation in the dissociation equilibrium to be as $e^{E_1/RT}$ to $e^{E_2/RT}$, where R is the gas-constant and T the absolute temperature. The next step is to determine the rate of transport of momentum through the medium. In the "vapour" part of the aggregation, the transport occurs by bodily movements. In the "crystalline" part, the rate of transport may be considered to be practically infinite. The effective rate of transport in the liquid is therefore greater than in the vapour at the same temperature and pressure in the ratio $e^{E_2/RT}/e^{E_1/RT}$. The viscosity of the liquid is therefore given by the formula $\eta_{liquid} = \eta_{vapour}\, e^{(E_2-E_1)/RT}$. Since $E_2 > E_1$ it follows that the viscosity of the liquid will *diminish* with rising temperature.

The next step is to determine the absolute magnitudes of the energy constants E_1 and E_2. As was first pointed out by Sutherland, in the cases of gases and vapours the attractive forces between the molecules tend to *increase* the frequency of collisions and thus *diminish* the viscosity. The matter has been further examined by Chapman, who has shown that Sutherland's constant is one-sixth of the mutual potential energy of the molecules when in contact. It is convenient to use an amended form of Sutherland's formula and write

$$\eta_{vapour} \propto T^{\frac{1}{2}}\, e^{-E_3/RT},$$

where E_3 is another energy-constant. From Chapman's work it would appear that $E_2 = 6E_3$, and we may also take $E_1 = E_3$. Hence, finally, we have

$$\eta_{liquid} = \eta_{vapour}\, e^{5E_3/RT}.$$

E_3 may be found from the data for the viscosity of vapour at different temperatures, and the formula thus enables the viscosity of the liquid to be calculated *a priori*.

To illustrate the matter, it will suffice to take the case of benzene as an example. The table shows the viscosity of liquid benzene at different temperatures as determined by Thorpe and Rodgers, and also as calculated from an empirical equation of the type $\eta = Ae^{B/T}$.

VISCOSITY OF BENZENE LIQUID.

$A = 0{\cdot}0000951$. $B = 1237$.

Temperature.	Calculated Viscosity.	Observed Viscosity.	Difference.
7·67°	0·00781	0·00789	+8
13·46	0·00714	0·00717	+3
19·39	0·00654	0·00654	0
25·96	0·00595	0·00595	0
32·07	0·00549	0·00547	−2
38·47	0·00504	0·00502	−2
45·35	0·00464	0·00461	−3
51·66	0·00429	0·00429	0
57·37	0·00403	0·00402	−1
63·29	0·00377	0·00377	0
69·41	0·00353	0·00354	+1
73·36	0·00332	0·00333	+1

Viscosity of benzene vapour at 100° C. = 0·0000930. $5E_3$ calculated from the value at 212·5° C. is 1300.

It will be seen that the formula represents the viscosity of the liquid within an average error of 2 parts in a thousand; and that the constants A and B are in fair agreement with the values calculated from the data for the viscosity of the vapour. An empirical formula of the type $Ae^{B/T}$ is found to represent closely the variation of the viscosity of many liquids, especially at the higher temperatures. As we have assumed that the "vapour" molecules are identical with those actually found in the gaseous state, we cannot expect the experimental constants A and B to agree exactly with those indicated by the theory outlined in this note in all cases. Considerable deviations actually occur in the case of "associated" liquids, in which presumably the effect of the molecular fields of force cannot be handled so simply.

The further discussion of this question and of the extension of the theory to the case of dense vapours on one hand, and to supercooled liquids and amorphous solids on the other hand, offers a most interesting field of research. The treatment suggested can obviously be improved in several directions, especially in the discussion of the dissociation equilibrium between the two types of molecules, and the effect of high pressures on the viscosity of liquids could probably be explained by a more exact investigation.

C. V. RAMAN.

Calcutta, India, March 1.

Colour Temperature and Brightness of Moonlight.

OUR more complete knowledge of full or black-body radiation embodied in Planck's law makes it possible to speak of the temperature of radiation as well as the temperature of radiating bodies. Thus, the temperature of any visible radiation is the temperature to which a black body must be raised to emit light as nearly as possible of the same integral colour or quality as that of the radiation in question.

The necessary "colour matches" involved in comparisons of a given radiation with that of a black body at a known temperature may be easily and quite accurately made with a contrast photometer. Radiation temperatures thus determined are called "colour temperatures." The colour temperature of the zenith sun as seen from the earth, according to Abbot's bolometric data, which extend into the infra-red spectrum, is 5600° abs. If correction is made for the absorption of the earth's atmosphere, we get a value of 6500° abs. for the colour temperature of sunlight above atmospheric limits. When a contrast photometer is used for making "colour matches" to determine colour temperature, a black-body source at a corresponding temperature is necessary for comparison. To avoid the necessity of a comparison black body at very high temperatures, advantage can be taken of Planck's formula for black-body radiation for computing a distribution of intensities in the visible spectrum which will give the integral colour of the source under examination, as measured by an optical pyrometer with monochromatic screens.

This procedure was followed in some observations made to determine the colour temperature of moonlight. The disappearing filament pyrometer with blue and red glass screens was focused on one of the brighter portions near the centre of the full September moon, 1916, when near the meridian. These readings were repeated under nearly the same conditions a year later. The colour temperature found for moonlight on the two evenings in question agreed to within 50°.

With the same pyrometer data we can also determine the brightness temperature of the moon for a given wave-length; that is, determine the temperature of a black body which has the same brightness or intensity for the same small wave-length interval chosen for comparison. Thus, with a red glass screen transmitting an average or effective wave-length of 0·665 μ, we may determine the brightness temperature of the moon for this wave-length. It is also possible, from the data thus obtained and the brightness of a black body, to calculate the brightness of the moon in candles per square centimetre. Thus, knowing the illumination due to the sun, the reflecting power of the moon for sunlight may be calculated.

The data determined from these various observations and calculations are shown in the following table:

Colour temperature of moonlight .	4125° abs.
Brightness temperature (λ=0·665 μ)	1575° abs.
Brightness for total light . .	0·25 candles/cm.^{2}
Reflecting power for total light .	0·07

The difference in colour temperature between the sun and sunlight reflected from the moon, 5600° and 4125° respectively, indicates that the observed area of the moon reflects selectively, the coefficient being about twice as large at the red end of the spectrum as at the blue. The greater difference in brightness temperature of these two is due to the low albedo or average reflecting power of the moon's surface.

Botanical Aspects of Wegener's Hypothesis.

IN the account which appeared in NATURE of January 27, p. 131, of the discussion on the distribution of life in the southern hemisphere, which took place before the Royal Society of South Africa, I am said to regard the botanical evidence as completely opposed to Wegener's theory. The remainder of the article generally followed the official report issued by the society.

My point was that the ancient phyla, with excellent means and ample time for dispersal, are generally valueless as indicating former land connexions. On the other hand, the distribution of the modern groups, especially the Angiosperms, in the South Temperate sub-continents took place in the main after the disruption envisaged by the Wegener theory. Thus neither ancient nor recent groups give us any material assistance in criticising this suggestive hypothesis, so far as concerns the relationships between the South American, South African, and Australasian floras. The botanical evidence for the southern hemisphere is certainly not "completely opposed" to Wegener's theory: it simply does not provide any critical test of that theory, so far as I can see at present.

R. H. COMPTON.

National Botanic Gardens,
Kirstenbosch, Newlands,
Cape Town,
February 26.

I ACCEPT Prof. Compton's correction of the phrase "completely opposed"; it is perhaps too strong a term to have used. Prof. Compton's letter, however, at least admits that the evidence from the botanical side is valueless as a critical test for or against

Wegener's hypothesis, and emphasises the fact that supporters of that hypothesis must look elsewhere than to the facts of animal and plant distribution for positive evidence in its support. Zoologists and botanists are dependent on the geologist and geophysicist for the correct interpretation of the palæogeographical changes which have taken place in the earth, and must be guided by them in selecting the basis on which the known geographical distribution of living forms can be explained.

THE WRITER OF THE ARTICLE.

Use of the Triode Valve in Spectrometry.

THE three-electrode valve offers a very simple and trustworthy method of amplifying the small currents produced in the thermopile of an infra-red spectrometer. Bright lines are more readily picked up and the limits of absorption bands determined with greater certainty with a valve and telephone than with a galvanometer. Moreover, the valve is instantaneous in action, while a sensitive galvanometer takes an appreciable time to give a trustworthy indication—so much so that the fainter lines are apt to be missed when using a long-period galvanometer. In the thermopile circuit an interrupter is necessary: this may take the form of a steel wire maintained in vibration electrically to which is attached a small wire dipper making contacts through a cup containing mercury. The interrupted thermopile current is passed through the primary of a small step-up transformer the secondary of which is connected to the grid of the valve.

For quantitative work the thermopile current is balanced by a potentiometer, a minimum of sound in the telephones indicating the point of balance.

The valve has a further advantage over the galvanometer in that it is unaffected by vibration or stray magnetic fields. The use of a valve for such work would seem to have many other applications, and to this end further experiments are being carried out.

The Release of Electrons by X-rays.

IN his interesting article, "Recent Advances in Photographic Theory," in NATURE of March 24, Dr. Mees touches upon the nature of X-rays and the mechanism of their production, and quotes Sir William Bragg's analogy of the plank of wood dropped into the sea.

I believe that Sir William Bragg put forward this analogy in a Robert Boyle Lecture, rather with a view towards successfully visualising the electron-X-ray process than of proving an individual relationship between them. One is tempted to say that an analogy never proves anything, although it may be thoroughly illuminating.

It is an extraordinary fact that a beam of X-rays will release electrons from an object which they hit, with just the velocity of the stream that originates the rays; it appears probable from energy considerations that this relation cannot hold down to the individual electron, so it might not be unprofitable if experiments were directed towards finding the limiting strength of the stream of electrons for the production of X-rays.

The Magnetic Disturbance of March 24–25.

A CONSIDERABLE magnetic disturbance occurred on March 24–25, as recorded by the Stonyhurst magnetographs. There was no marked sudden commencement of the disturbance, but the declination magnet began to move steadily towards the W., accompanied by a decrease in horizontal force, between the hours 8 and 9 G.M.T. The declination magnet attained the extreme limit of its westerly movement at 13 h. 14 m., when it began to move gradually towards the E. At 17 h. 12 m. a period of rapid oscillations commenced on the declination magnet. On the horizontal force magnet the decrease in force was succeeded, at 12 h. 24 m., by an increase. A very rapid oscillation of increase and decrease occurred between 17 h. 2 m. and 17 h. 18 m., the range being 88 γ (1 $\gamma \equiv 10^{-5}$ C.G.S. unit).

A quieter period ensued on the declination magnet between 18 h. 24 m. and 21 h. 12 m., while the horizontal force magnet, after the rapid oscillation at 17 h. 2 m., showed a gradual decrease in force, which reached its limit at 18 h. 48 m. A remarkable rapid oscillation, to E. and return to W., occurred on the declination magnet, between 21 h. 12 m. and 21 h. 26 m., the range of the oscillation being 38′. This was accompanied on the horizontal force magnet by an even more noteworthy rapid oscillation of increase and decrease of force, of range 189 γ, between 21 h. 24 m. and 21 h. 50 m.

The only other notable feature of the disturbance was a bay in both elements, between March 25, 2 h. 12 m., and 3 h. 0 m., the range in declination being 16′, and in horizontal force 97 γ. The more violent phases of the storm had ceased by March 25, 8 h. The extreme ranges were, in declination 1° 6′, and in horizontal force 238 γ. The vertical force magnet showed a general movement, with oscillations, of increase and decrease of force between the hours March 24, 17 h. 12 m., and March 25, 4 h. 24 m. This would indicate the period of the greatest activity of the disturbance. The sensibility of the magnet is uncertain, but the extreme range was about 80 γ.

A disturbed period in magnetic activity occurred on February 25–28, so that this storm follows after an interval of 27 days, the synodical rotation period of the sun. But the solar surface has been unusually quiet during the past two months, at least so far as spots, which have been very few and of small area, and faculæ, which have been very faint, are concerned. The connexion of these disturbances with solar phenomena will require further elucidation. Father Dechevrens, *S.J.*, recorded strong earth-currents at his observatory, St. Louis, Jersey, during the February disturbance. It will be interesting to hear of any observations of aurora borealis.

Pressure of Fluidity of Metals.

MR. HUGH O'NEILL, in his letter in NATURE of March 31, p. 430, gives what he calls H_u, the "ultimate hardness" of tin, zinc, and steel. On referring to my letter at p. 17 of NATURE of January 6, it will be seen that H is there used for H_u, and that the pressure of fluidity = *twice* the ultimate hardness. The units of H_u given at p. 430 are evidently kilograms per sq. mm. Expressing these in kilos per sq. cm. and multiplying by 2 we obtain the following values of the pressures of fluidity as calculated by Mr. O'Neill

by means of his equation given at p. 773 of NATURE of December 9, 1922.

Metal.	Pressure of Fluidity.
	Kilos per sq. cm.
Tin	1,080
Zinc . . .	5,000
Steel A . . .	19,200
Steel S90 . .	33,600

I have recently (with the generous aid of Mr. R. H. H. Stanger of the Broadway Testing Laboratories, and the following firms who prepared and presented the necessary three specimens of each metal) determined the pressures of fluidity of several metals by direct experiment, so it will be interesting to compare the results, remembering of course that the specimens were *not* made from the same piece of metal as those used by Mr. O'Neill. In the case of my tests the three specimens of each metal were made from the same piece.

The British Aluminium Co. Ltd. supplied the specimens of aluminium.

Messrs. David Colville and Co. Ltd. supplied the specimens of mild steel.

Messrs. Dewrance and Co. supplied the specimens of tin, lead, and zinc.

The Elliott's Metal Co. Ltd. supplied the specimens of copper.

The Muntz's Metal Co. Ltd. supplied the specimens of Muntz's metal.

The experiments were made not merely to determine the pressures of fluidity, but also to test an hypothesis to account for the phenomenon of pressure of fluidity. This hypothesis is far too long to reproduce here, but it will be found in the Transactions of the Society of Engineers for the quarter January-March 1923. It connects the pressure of fluidity with the ultimate shearing and tensile strength of the metal, and was devised in connexion with experiments with clay, and then found to apply to plastic metals as well.

If p be the pressure of fluidity in kilos per sq. cm.,
f be the shearing stress in kilos per sq. cm.,
c be the ultimate tensile strength in kilos per sq. cm.,
then the hypothesis shows rationally on the assumptions made that

$$p = 3{\cdot}68c + 5{\cdot}21f. \quad . \quad . \quad . \quad (1)$$

The pressures of fluidity were determined by means of cylindrical specimens 70 mm. in diameter and 70 mm. high, using a flat-nosed punch 10 mm. in diameter at the end and reduced in the shank to 9 mm. so as to clear the sides of the hole.

Metal.	Tensile Strength c.	Shearing Strength f.	Pressure of Fluidity p.	p' the calculated Value of p.	$\frac{p'-p}{p'}\times 100$.
Lead . . .	114·5	125	777	1,072	+27·5
Lead-tin alloy	244·0	156	1,233	1,706	+27·7
Tin . . .	223	232	1,367	2,025	+32·5
Aluminium .	827	577	4,015	6,045	+33·6
Copper . .	2192	1445	10,860	15,590	+30·1
Muntz's metal	3686	2004	(16,800)*	23,966	
Mild steel .	4380	2990	(22,140)*	31,625	Mean +30·3
Zinc . . .	214	755	[7,760]	4,707	..

All stresses are in kilograms per sq. cm.

* These are *not* experimental values, but merely predictions.

The relation given by equation (1) thus on the average gives results which need reducing by 30 per cent. to arrive at the actual values, and the maximum departure from this mean is 3·3 (aluminium).

Zinc is a rank outsider as regards this hypothesis! But zinc has no plasticity. It did not elongate or show any contraction of area under a tensile force. In shear even it failed by tension, and when the pressure of fluidity experiment was made, the specimen gradually burst by yielding in tension on several vertical planes.

With regard to the variation of the figures in the last column, it must be remembered that these depend on the experimental values of f and c, which themselves vary. For example, in the case of the shearing tests, two experiments were made with each metal, the planes of shear being about one inch apart on the same specimen. For all this the values of f differed by 4·3 per cent. and 5·5 per cent. in the cases of tin and aluminium respectively.

Use of the Millibar in Aerodynamics.

THE millibar, introduced by Sir Napier Shaw into British meteorology, brings the same drastic simplification into the numerical relations between pressure and velocity in aeronautics.

The accompanying diagram (Fig. 1) shows the

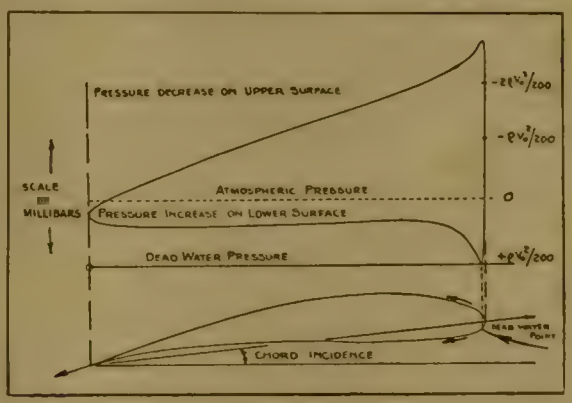

FIG. 1.

pressure distribution round a wing profile, calculated in accordance with Joukowsky's theory.

In C.G.S. units $p - p_0 = \frac{1}{2}\rho \cdot (v_0^2 - v^2)$ dynes/cm.^{2} or microbars, where p, v are the variable pressure and velocity at points on the profile, p_0, v_0 the values at a distance, and ρ the density of the air.

Expressing ρ and v in M., Kg., S. units, which are more convenient for aeronautical measurements,

$$\begin{aligned}\text{pressure} &= \tfrac{1}{2}\rho \cdot (v_0^2 - v^2)\ \text{m.kg.s.}^{-2}\text{m.}^{-2} \\ &= \tfrac{1}{2}\rho \cdot (v_0^2 \cdot 10^{-2} - v^2 \cdot 10^{-2})\text{mb.} \\ &= \tfrac{1}{2}\rho \cdot 10 \cdot (v_0^2 \cdot 10^{-2} - v^2 \cdot 10^{-2})\ \text{megadynes/m.}^2.\end{aligned}$$

The last two forms lend themselves to computation, since flying speeds usually lie between 10 m./s. and 100 m./s. The absence of all extraneous factors save integral powers of ten is sufficient proof of the practicality of Sir Napier Shaw's action.

In the minority of cases where the forces considered are produced by the action of gravity on known masses, they are easily transformed, for the megadyne is $10/9{\cdot}81 = 1{\cdot}02$ kgm. weight, and the millibar is $1000/981 = 1{\cdot}02$ cm. head of water with an accuracy amply sufficient for aeronautical measurements.

London, March 22.

The Sun-Cult in Ancient Egypt.[1]

By AYLWARD M. BLACKMAN, D.Litt.

II.

IT has often been maintained that the Aton-cult instituted by Ōkhnatōn (Amenōphis IV.) displays non-Egyptian features and is in a large measure the product of foreign influences. I hope, however, clearly to show here that in the main it is the outcome of certain tendencies of the old solar religion discussed in the previous article — tendencies which had begun to manifest themselves so far back as the Old Kingdom, which came increasingly into evidence during the Middle Kingdom and the eighteenth dynasty, and finally found in the teaching of King Ōkhnatōn a somewhat particularised expression.

It was pointed out in the first article that the sun-god, owing to the political and religious importance of Heliopolis, became at a very early date the State-god of Egypt, and that the priests of a number of the local gods, in order to enhance their prestige, identified them with the sun-god, the goddesses who were associated with these gods being identified with Ḥathor, the sun-god's consort. There was also, it must be noted, a distinct tendency to identify the various divinities with one another, thus considerably reducing their number as separate entities in the Pantheon. All this, combined with the prevailing uniformity in the structure and equipment of the temples, the temple liturgy, and the organisation of the priesthood—a uniformity due to the predominant influence of Heliopolis—fostered the growth of monotheistic or, anyhow, henotheistic ideas.

During the Middle Kingdom, when a Theban line of kings ruled over a united Egypt, Amūn, the local god of Thebes, was identified with the sun-god, being henceforth known as Amunrē'. As a result of the imperial expansion of Egypt under the Theban emperors of the eighteenth dynasty, the sun-god, originally the national god of Egypt and the prototype of the Egyptian Pharaoh, became in the person of Amunrē' a world-god and a world-ruler. Thus the victorious Tethmōsis III. says of Amunrē' that "he seeth the *whole world* hourly." A hymn in praise of the sun-god, written in the reign of Amenōphis III., the father of Ōkhnatōn, speaks of the sun-god as "the sole lord taking captive all lands every day, as one beholding them that walk therein." The once merely national god has thus become a deity who exercises universal sway and possesses universal vision.

But the god of this hymn is not only the all-powerful, all-seeing ruler: he is also the beneficent protector and sustainer of mankind—"the valiant herdsman who drives his cattle, their refuge and the giver of their sustenance." It will be remembered, of course, that the sun-god appeared already in the literature of the seventh to eighth dynasties in the guise of "the shepherd (or herdsman) of all men." This same hymn further emphasises the sun-god's beneficent nature in calling him "a mother, profitable to gods and men." As is so frequently maintained in the religious literature of the Imperial Age, this hymn also asserts that the sun-god is the source of all, including his own, being. "Thou art the craftsman shaping thine own limbs; fashioner without being fashioned."

From this and other compositions it can be seen that the religious thought of the period just preceding the reign of Ōkhnatōn was distinctly monotheistic in its tendency. It was only necessary to advance this tendency a step or two further to arrive at actual monotheism. This is what Ōkhnatōn did when he asserted definitely once and for all that the sun-god was not only the supreme and universal god, but also the only God—an assertion that had never been definitely enunciated by the theologians who had preceded him, but had only been sporadically and somewhat vaguely hinted at by them.

The universality of Ōkhnatōn's god is clearly set forth in the famous hymn, which so closely resembles the 104th Psalm, and of which the king claims, probably with right, to be the author. The sun-god is represented as the All-Father, the source of all life. He it is who has created the different nations and assigned them their divers complexions and languages. He has also provided for their sustenance, making the Nile to well up out of the nether world to water the land of Egypt, but setting a Nile in the sky for other peoples, whence it comes down as rain. "Thou didst make the distant sky in order to rise therein, in order to behold all that thou hast made. . . . All men see thee before them, for thou art Aton of the day aloft."

There has been a certain amount of controversy as to whether Ōkhnatōn was actually himself responsible for the establishment of this monotheistic sun-cult. As has been stated at the beginning of this paper, some scholars incline to the view that the Aton-cult is distinctly of foreign origin and that its being established as the State-religion was due to the influence of Tyi, herself a foreigner, by whom her son Ōkhnatōn was completely dominated. Others, again, have maintained that the establishment of this cult was due to the successful intrigues of the Heliopolitan priests, who, attaining the ascendancy over a weak king, temporarily regained the religious hegemony of Egypt.

Those who take the view that the religious revolution was the work of Tyi and foreign influences, or of an intriguing priesthood, find the main support for their respective theories in the fact that the body, supposed to be that of Ōkhnatōn, is that of a man who could not have been more than 25 to 26 years old when he died, while the skull shows distinct signs of hydrocephaly, indicating that the person in question was weak intellectually. As Ōkhnatōn is known to have reigned for more than sixteen full years, he can, if this is his body, have been only ten or eleven years old when he came to the throne and the religious revolution began, and only sixteen or seventeen when he definitely broke with the priests of Amūn, changed his name from Amenḥotpe to Ōkhnatōn, and deserted Thebes and founded his new capital at El-Amarna. Yet before this change in name and residence two of his daughters, as a relief distinctly shows, were old enough to accompany him when he officiated at the temple liturgy, and, moreover, before the aforesaid change

[1] Continued from p. 502.

took place, *i.e.* before the sixth year of his reign, we happen to know that Ōkhnatōn celebrated the so-called *sed*-festival, a festival marking the 30th anniversary of the Pharaoh having been designated heir to the throne. Had it not been for the age-limit imposed by Ōkhnatōn's supposed body, we should naturally have imagined, in view of this last piece of evidence, that when he succeeded his father, Amenōphis III., he must have been at least 24 or 25 years old.

As a matter of fact, however, though the coffin in which the body was found was beyond question made for Ōkhnatōn, yet the body itself is almost certainly not his, the date of the objects found thereon, as Prof. Sethe has recently shown, precluding that possibility.

There can be little doubt, therefore, that Ōkhnatōn was a full-grown man when he came to the throne, while at the time of his break with the priests of Amūn and his shifting of the capital to Middle Egypt he was more than 30 years old, and accordingly at the height of his intellectual and physical vigour. The fact that Ōkhnatōn's supposed body is not his at all also disposes of the theory that he was weak mentally. There is, therefore, no necessity whatever to suppose that the new faith, which contemporary records so closely associate with the person of the king and which he was certainly quite old enough to have formulated, was the product of foreign influences during a regency of Tyi, nor yet of the Heliopolitan priesthood struggling for a religious and political supremacy. That Ōkhnatōn really was a man of exceptional mental gifts and high ideals—Breasted calls him "the first individual in history"—is evident from that remarkable portrait of him found at El-Amarna in 1912 and now in the Berlin Museum. All who see it are impressed by the beauty of the features and expression, the thoughtfulness pervading the whole countenance.

We need not, however, go to the other extreme, as some writers have done, and regard the love of righteousness and the beneficence attributed to Ōkhnatōn's god as primarily the expression of the king's own ideas and feelings. On the contrary, as has been pointed out in the preliminary article, these are the very qualities assigned to the old Heliopolitan sun-god. How far, indeed, the old solar religion had advanced in these particular directions, even before the Middle Kingdom, is especially evident in a literary composition of the ninth to tenth dynasties, to which by an oversight no reference was made in the above-mentioned article. In one portion of the work in question the ancient writer speaks of men as "the flocks of God (*i.e.* the sun-god)." God, he goes on to say, "made heaven and earth at their (*i.e.* men's) desire. He checked the greed of the waters, and made the air to give life to their nostrils. They (men) are His own images proceeding from His flesh. He arises in heaven at their desire. He sails by (*i.e.* in the celestial solar barque) in order to see them. . . . When they weep He heareth. . . . How hath He slain the froward of heart? Even as a man smiteth his son for his brother's sake. For God knows every name."[2] In the preceding section of the same work we read that "more acceptable (to the sun-god) is one righteous of heart than the ox of him who doeth iniquity."

That Ōkhnatōn's sun-cult is nothing more than a special development of the older sun-cult becomes only more evident the further one pursues one's researches. In the earliest stage of the cult the god appears simply in the guise of the Heliopolitan sun-god, Rē'-Horus of the Two Horizons (Rē'-Harakhte), with whom indeed, as we shall see, he was actually identified. As such he is depicted as a human figure with a hawk's head surmounted by the uræus-encircled sun's disk. Later on, however, but before the migration of the court to El-Amarna, the mode of representing the god was entirely changed. He was depicted as a solar disk, from which descend rays terminating each in a human hand—these hands being the only trace left of the old anthropomorphism, if they are not, as is quite likely, simply an expression of poetic fancy. The uræus was also retained, sometimes hanging from the disk, generally, however, rising up from the bottom edge towards the centre, though it was of no religious significance, but merely the emblem of kingship—Ōkhnatōn's deity being not only the world-god but the world-king.

The name of the new god in ordinary everyday parlance was *pa Aton*, "the Aton," aton (*itn*) being the word used then and earlier to denote the visible, physical solar body, though, as Sethe points out, the word seems occasionally to have been employed, even before Ōkhnatōn's time, to designate the sun-god himself. Generally, however, it just denotes the sun as a natural phenomenon or cosmic body, as distinguished from the god dwelling in it, a sense in which the word Rē' is never used.

According to the old theological teaching the physical sun was simply the embodiment of the god. Thus we read of "Atum (the sun-god) who is in his *aton*," "Rē' whose body is the *aton*," and him "who lightens the Two Lands (Egypt) with his *aton*." In fact, it was exactly on account of the very definite meaning of the word *aton*, Sethe maintains, that Ōkhnatōn chose it as the designation of his god; for the new religion was entirely materialistic in its conception of the Supreme Deity, in marked contrast to the—it must be confessed—much more spiritual conception of the old religion. Indeed it is just here that Breasted has gone astray when he asserts that "it is evident that the king was deifying the force by which the sun made itself felt on earth,"[3] an assertion that is based on a mistranslation of the Aton's official nomenclature (see below). On the contrary, it was the actual cosmic body, the physical sun itself, not a mysterious power incorporated in it or working through it, which Ōkhnatōn made his subjects worship.

In addition to the ordinary name, the Aton, the god also bore an official or formal designation, the words composing it constituting a short profession of faith—a compressed creed. This designation, which, on account of the god's world-wide kingship, was, like the two names borne by every Pharaoh, enclosed in two cartouches, appears in two forms, an earlier and a later. The earlier, which dates from the very commencement of the reform, and continued in use until after the seat of government had been moved from Thebes to El-Amarna, is as follows:—"Liveth Rē'-

[2] A. H. Gardiner, "New Literary Works from Ancient Egypt," in *Journal of Egyptian Archæology*, vol. i. p. 34.

[3] Breasted, "Development of Religion and Thought in Ancient Egypt," p. 321.

Horus of the Two Horizons, rejoicing in the horizon, in his name Shu who is Aton." The new god is thus identified with the two forms under which the sun-god was known both before and after the reign of Ōkhnatōn —Harakhte (=Horus of the Two Horizons) and Shu. The epithet "rejoicing in the horizon" is not, Sethe points out, an invention of Ōkhnatōn's, but appears earlier in the eighteenth dynasty as a description of the sun-god. Shu, originally personified space, was, as Sethe also points out, a common appellation of the sun-god from the Hyksos period onwards, and never (certainly not as written in this cartouche with the sun-determinative) can be used in the sense of "heat" or "splendour," as Breasted and Erman respectively have supposed. Sethe rightly maintains that the prominent feature in this official nomenclature is the element Rē'-Harakhte, the name of the Heliopolitan sun-god, all the rest, even the name Aton, being purely subsidiary.

The later official designation, which came into force apparently soon after the eighth year of the king's reign, is marked by certain significant changes. It runs as follows:—"Liveth Rē', the ruler of the Two Horizons, who rejoices in the horizon, in his name Father of Rē', who has come as Aton."

It will be seen that Horus and Shu, names which Ōkhnatōn perhaps thought were too definitely associated with the old religion, have been struck out and replaced by two epithets, "Ruler of the Two Horizons" and "Father of Rē'." The name Rē', which has not been interfered with, had been, as Sethe points out, a regular element in the Pharaoh's first cartouche ever since the fifth dynasty, and as such was of no theological significance. Also the king evidently had no objection to this old name of the sun-god. For example, he still retained the royal title Son of Rē'; Rē' appears as an element in his own first name and in the names of his two daughters; two temples or shrines associated with his mother Tyi and his daughter Meritaton bore the name "Shade of Rē'"; and the king himself, like other Pharaohs, is officially spoken of as Rē'.

The element "Father of Rē'" in the god's official designation is interesting, taking as it does the place of Shu. Shu, according to the old Heliopolitan theology, was the son of Rē', and as such he actually was assigned that title. It would, Sethe suggests, have been scarcely tolerable to the founder of the new religion that Aton, the creator and author of all being, should be regarded as the son of Rē', the sun-god of the old religion. Ōkhnatōn therefore asserts that his god is the father of Rē', *i.e.* he makes him cosmically older. The fact that the god is called Rē', and, at the same time, the Father of Rē', reminds one of the old epithet of Amūn, Bull of his Mother, which simply means that he is self-created, that is, that he was not begotten by another. Sethe rightly maintains that though this epithet has a polytheistic touch about it, Ōkhnatōn would have been as little conscious of this as were the Christian Fathers when they formulated the doctrine of the Blessed Trinity.

Sethe directs attention to another very interesting point in this later designation of the god. "To come," he says, "has obviously here, as so often, the meaning of 'to come again.' The Father of Rē' in question is thought to have come again after he had obviously disappeared or had been mistaken for another through man's ignorance, and indeed he has come again in the form of the apparently new but in reality primæval god of Amenōphis IV."

Let us now consider briefly the temples of the Aton erected at El-Amarna and the liturgy celebrated therein. The main difference between the temples of the Aton and those of the old Solarised religion lies in the fact that the former seem to have been roofless. There were thus no columned halls and dark, mysterious sanctuaries with their surrounding chambers, the place of these being taken by a series of main and subsidiary courts lying behind the forecourt and leading one out of another. The reason for this architectural change was that Ōkhnatōn permitted no cultus-image of his god to be made, not because he was an iconoclast or afraid of idolatry, but because his conception of God was so intensely materialistic. The Aton, as already pointed out, was the actual physical sun, the cosmic body itself, not a divinity dwelling in that body and manifesting himself through it, and therefore ready similarly to manifest himself through a cultus-image, which was "the body" of the divinity it represented, according to the ideas of the ancient theologians—as we should express it, the divinity's embodiment. Offerings had, therefore, to be made direct to the god in the sky, a procedure which necessitated a roofless temple, for no roof must intervene between the god and the offerings held up to him and laid on the altar.

Despite this complete break with the old conception of the indwelling presence of the god in the temple-sanctuary,—a conception which brought the god so near to his priests and worshippers—it is remarkable how closely in many respects the general plan and equipment of the traditional Egyptian temple were adhered to, a clear indication that there were no direct foreign influences at work in the new religion; indeed, the architecture down to the very last detail is purely Egyptian. We still find the pylon with its two beflagged towers and the great forecourt with its large stone altar in the midst[4]—the forecourt being colonnaded in the case of the temple bearing the name of "Shade of Rē' of the Queen Mother, the Great Royal Wife, Tyi." Evidently, too, the rearmost court of all in the Aton-temples, which occupied the place of the sanctuary in the ordinary Egyptian temple, was regarded as particularly sacred. Again statues of the king and also of the queen were set up as heretofore in different parts of the temples, the king and queen being thus enabled, so it was thought, to function perpetually as worshippers and offerers, or conversely as the recipients of worship and offerings. Yet again, before the entrance to what N. de G. Davies calls "the inner temple" of the Aton stood eight tanks of water for the purification of those who entered it. Such tanks or pools of water were, as pointed out in the preliminary article, a characteristic feature of the old Heliopolitan sun-cult. Finally, the "inner temple" was called the House of the Benben, the *benben* being, as we have seen, the sacred pyramidion in the great sun-temple at Heliopolis. Curiously enough, in the representations we possess of Ōkhnatōn's Aton-temples,

[4] By an oversight no reference was made in the account of an ordinary Egyptian temple, given in the preliminary article, to the stone altar that always stood in the colonnaded forecourt.

no obelisks (which were so closely associated with the old sun-cult) are depicted as standing before the main entrance or elsewhere in the sacred precincts. However, we know that Ōkhnatōn erected an obelisk in honour of Harakhte-Aton at Karnak, probably in connexion with his *sed*-festival celebrations.[5]

The Aton-temple liturgy itself is clearly the old temple liturgy adapted to the new ideas and new requirements. As there was no cultus-image, there was no place in the new worship for the toilet, or indeed many of the pre-toilet, episodes of the old liturgy. The worship of the Aton seems to have consisted mainly in the presentation to the god of food- and drink-offerings, perfumes, and flowers, and in the chanting of hymns and in musical performances in general. But the ceremonies connected with the presentation of offerings were those of the old religion, the officiant consecrating the offerings in the time-honoured fashion, *i.e.* by extending over them the so-called *kherp*-baton. As in the old liturgy, this ritual act was preceded by the burning of incense and the pouring out of a libation of water; indeed, the burning of incense and the pouring out of a libation were, as in times past, the regular accompaniments of every act of offering. The liturgy was celebrated, as of old, to the accompaniment of the rattling of sistra, and also of other musical performances, vocal and instrumental. Lastly, it should be pointed out, the ceremony of sweeping the floor—the removal of the foot-prints—before and after the celebration of the liturgy seems almost certainly to have been retained.

This article cannot be satisfactorily concluded without a brief discussion of two important questions that have already been touched upon in the preceding paragraphs, namely, Ōkhnatōn's quarrel with the priests of Amūn, and the theory advanced by some scholars that in the establishment of the Aton-cult we are to recognise a temporary restoration of the political and religious supremacy of the Heliopolitan priesthood.

Long before the time of Ōkhnatōn the Theban god Amūn had been completely identified with the Heliopolitan sun-god. What, then, was the cause of the king's rupture with the priests of Amūn and his breaking away from all Theban influences?

It must be borne in mind that the monotheistic tendencies of the preceding period had in no way affected the customary performances of the old institutional religion. Whatever may have been the speculations and ideas of the learned and enlightened few, the worship of the gods was conducted in exactly the same way as it had been for centuries, without a single hint at a change in the traditional ceremonial. Ōkhnatōn's religious revolution, on the other hand, not only entailed a great change in the conduct of the temple services and far-reaching structural alterations in the temple buildings, but also, since the king would brook no rival to his god, the suppression of all the festivals and other performances connected with the provincial cults and with the various cults established at the capital. All this was a completely new attitude in Egyptian religious experience; indeed we are encountering the "jealous God" for the first time in human history, several centuries before His appearance among the Hebrews. The feelings both of the priests and of the masses of the people must have been deeply stirred by this attack on their religious observances, particularly in so far as it affected the festivals celebrated in honour of the local divinities, festivals which no doubt played as great a part in the lives of the people as do those celebrated in honour of the local Egyptian saints at the present day.[6] In fact, there can be no question that Ōkhnatōn's reform meant far too sharp a break with the past for his intensely conservative-minded subjects.

It should here be pointed out that so early as the reign of Tethmōsis III. all the priesthoods of Egypt had been combined in one great organisation, with the high-priest of Amūn at their head. To the high-priest of Amūn, therefore, and to the priesthood of Amūn as a whole, all the local priesthoods would have looked to champion their threatened rights, while in Ōkhnatōn's eyes this very high-priest and priesthood would have appeared as the embodiment of all the forces of reaction against which he was struggling. Herein lay quite sufficient cause for his breaking away entirely from Thebes and the Theban god. We must also remember that Ōkhnatōn's materialistic conception of the Aton was entirely opposed to the—as already pointed out—much more spiritual conception of the sun-god formulated by the theologians of the old religion. It was impossible to regard the actual corporeal and localised divinity, such as Ōkhnatōn maintained his sun-god to be, as capable of identification with a being (or beings) who could manifest himself (or themselves) in all manner of forms and in many places. Did the cause of the final rupture reside in this difference of conception as to the nature of the Godhead? If so, we have here a foretaste of those great theological controversies which troubled the Christian Church of the first five centuries, and of the seventeenth-century wars of religion.

Let us now briefly consider the theory that in the institution of the Aton-cult we are to recognise the restoration of the political and religious supremacy of Heliopolis. In view of all that has been set forth in the preceding paragraphs, the Heliopolitan sun-cult is clearly to be regarded as the basis of the new religion, or rather as supplying all the material out of which the new edifice was constructed. On the other hand, the particular shape that that edifice assumed must be regarded as the work of Ōkhnatōn. If the sun-cult had been officially promulgated by the organised priesthood of Heliopolis or, as Borchardt[7] suggests, of Hermonthis (Heliopolis of Upper Egypt [*Iwnw šmʿ*]), Ōkhnatōn, instead of founding an entirely new capital at El-Amarna, would have been obliged to install the seat of government in or very near the actual official centre of the religion he had adopted. But he was able to act as he did, because the religion he professed was regarded as a completely new religion, a special revelation to himself, as he distinctly asserts. It was therefore not associated with any particular locality, so he was free to make his capital in any place that seemed to him to be most free from the old traditions and best adapted to his requirements.

Lastly, just a few words on the frequently-made assertion that foreign influences are discernible in the

[5] Schäfer in *Amtliche Berichte aus den preussisch. Kunstsammlungen*, xl. 10, col. 227.

[6] See W. S. Blackman, "Festivals celebrating Local Saints in Modern Egypt," in *Discovery*, vol. iv. No. 37, pp. 11-14.

Aton-cult. That there are no traces whatever of such influences, but that the Aton-cult is in every respect essentially Egyptian, the facts set forth in this article must have made perfectly clear. However, it is possible that Ōkhnatōn had foreign blood in his veins, for Prof. Elliot Smith maintains that his maternal grandfather, Iuyu, is distinctly non-Egyptian in type. To this dash of foreign blood, therefore, may well be due the originality clearly displayed by Ōkhnatōn in the particular expression which he gave to a certain trend of religious thought prevailing among his contemporaries.

Scientific Investigation of the Whaling Problem.

By Sir SIDNEY F. HARMER, K.B.E., F.R.S.

THE Colonial Office has recently announced that the *Discovery* has been purchased by the Crown Agents for the Colonies, on behalf of the Falkland Islands, for employment in researches, principally on whaling, off South Georgia and the South Shetlands. The *Discovery* was built for Capt. R. F. Scott's first Antarctic Expedition (1901–1904). She is a strong wooden vessel of about 700 tons register, and she has been chosen with special reference to her suitability for ice-work.

Subantarctic whaling commenced at the end of 1904, at a time when the industry was regarded as almost obsolete, owing to the exhaustion of the old whaling fields. It increased with so much rapidity that more than 10,000 whales were caught during the season 1911–12. At first concerned almost exclusively with the humpback, the operations are at present supported almost entirely at the expense of the much larger fin whale and blue whale. Humpbacks showed an alarming decline in numbers after the 1911–12 season, though they have made some recovery during the last two whaling seasons.

It should be realised that modern whaling is carried on by comparatively small steam vessels fitted with appliances for the capture of the whales, the products of which are worked up by factories on shore or by larger steamers, the floating factories. In either case, suitable harbours are required as bases, and the most favourable localities at present known are South Georgia, which lies to the east of the Falkland Islands, and the South Shetlands, which are farther to the south-west. These islands are dependencies of the Falkland Islands, and are accordingly under British jurisdiction.

As the result of several memoranda which were prepared in 1917 by Mr. E. R. Darnley, of the Colonial Office, an Interdepartmental Committee on research and development in the dependencies of the Falkland Islands was appointed by the Secretary of State for the Colonies in 1918; and its report (Cmd. 657) was published in 1920. The report contained a number of recommendations with regard to the investigations which were required; and the purchase of the *Discovery* is the first practical result of these suggestions. It should be mentioned that an earlier Anglo-Swedish scheme for the investigation of the same problems was abandoned on the outbreak of war in 1914.

The object of the projected voyages is to obtain scientific evidence bearing on the whaling problem generally, with the view of ascertaining to what extent protective measures are required. It has to be determined, in the first instance, what are the species of whales which are being hunted. Although known to the whalers as humpback, fin whale, and blue whale, it is uncertain whether these are identical with the northern whales known by the same names. Whales are migratory animals, and there can be no reasonable doubt that they visit the Antarctic Ocean in order to profit by the rich food-supply of its waters, and that they afterwards depart, fatter than when they arrived, to warmer waters, which are probably visited for breeding purposes. More definite information is required with regard to these migrations, and it is hoped that it may be possible to obtain direct evidence by a system of marking individual whales.

The period of gestation, the seasons when pairing and birth take place, and the rate of growth after birth all need further study. The plankton requires investigation, in view of the dependence of the whales on it for food; while the temperature of the water, with other hydrographical questions, has to be studied, in order to ascertain how far these factors influence the movements of whales. There is already some reason to suppose that the position of the northern edge of the Antarctic ice is a factor which is correlated with the success or failure of a season's working. If the summer is relatively warm the ice will be too far to the south and the whales will probably be too distant from the base. If the summer is cold the whales will be too much to the north. It may be anticipated that there is an optimum position for the ice which brings the main stream of whales to the neighbourhood of the whaling stations.

Although whalebone whales all feed on plankton, individual species are known to have a preference for one kind of plankton rather than another. In most localities the humpback consumes a considerable amount of fish, while the blue whale is said to feed exclusively on Crustacea. The distribution and the seasonal occurrence of various kinds of plankton, and the examination of the stomach-contents of whales, are matters with which the expedition will certainly have to deal; and the results may prove to have a

distinct bearing on the question why each species of whale differs from the others in its seasonal occurrence. The abundance of whale-food is dependent on conditions favourable for the growth of diatoms and other chlorophyll-containing organisms; and in this connexion may be mentioned Mr. A. G. Bennett's interesting observation that the skin of certain whales is covered by a film composed of innumerable diatoms. The evidence is in favour of the view that this skin-film is not present on thin individuals which have recently come down from the north, but that it develops during the stay of the whales in Antarctic waters. The study of the film and perhaps of whale-parasites may prove to be capable of giving important information with regard to migrations.

For many years the Norwegians have taken the leading place in the whaling industry, and they have large interests in Antarctic whaling. It is thus natural that they should feel anxiety with regard to the possible results of a protective policy, and this is shown by an article recently published in the *Anglo-Norwegian Trade Journal* (Vol. 9, No. 98, February). The comments in question were a rejoinder to criticisms of the whaling industry which had appeared in the *Morning Post*, based on a lecture given by myself, as reported in NATURE (Vol. 110, December 16, 1922, p. 827). I had pointed out, on the incontrovertible evidence of history, that the operations of whalers in the past have been invariably followed by a depletion of the whaling fields. The Atlantic right whale no longer frequents the Bay of Biscay in numbers sufficient to maintain a whaling industry, nor is the Greenland whale still common in the bays of Spitsbergen, in Davis Straits, or even in the North Pacific. The grey whale disappeared long ago from the lagoons of California, and there is no longer occupation for the hundreds of vessels which left European and American ports annually, in the eighteenth and part of the nineteenth centuries, in pursuit of the Greenland and other right whales and the sperm whale. With these facts in view the least that is required is the adoption of a cautious policy, lest the mistakes of the past should be repeated.

The whaling companies are admittedly interested in the avoidance of extermination, which would mean the closing of their operations, but their advocates have maintained that, in view of the enormous extent of the oceans which are frequented by whales, the activity of hunters in a small area is not likely to produce much effect in reducing their number. It will be seen, however, by consulting a map, that South Georgia and the South Shetlands lie in the region where the Antarctic Ocean is narrowest, and that they are admirably situated to intercept the stream of whales in their circumpolar movements. It would not be surprising if operations at these stations alone were found capable of depleting very seriously the entire stock of Antarctic whales, even if no new stations were to be founded in other localities, as seems likely to happen in Ross Sea, for example. The danger is all the greater, taking into consideration the highly efficient methods of modern whaling.

The acquisition of a sound body of scientific evidence is the object of the expeditions which are being planned by the Colonial Office. Although I do not conceal my personal conviction, as at present informed, that whaling is being conducted on too large a scale, I do not deny that a study of the subject by competent investigators on the spot may lead to a different conclusion. The Trustees of the British Museum have acted in an advisory capacity to the Colonial Office since they first became interested in Antarctic whaling, not long after its inception. I am authorised to state that they do not desire to take up an extreme position in the matter, but that their efforts are directed to the restriction of whaling to an extent which is not inconsistent with the permanent preservation of whales. This is a moderate view, with which it may be hoped that the representatives of the whaling industry will agree in principle. The article to which I have referred virtually admits as much, and the willing co-operation of the whaling companies will be of the greatest value to the expedition. It may be hoped that it will be possible to find a *modus vivendi* satisfactory to both parties, who are equally interested in preventing the extermination of whales.

Einstein and the Recent Eclipse.

THE results of the expeditions from Canada and the Lick Observatory to Wallal, Western Australia, for the solar eclipse of last September have now come to hand; and both report in favour of the Einstein shift of starlight. In each case the number of stars measured was very large—exceeding eighty—the magnitudes being between the seventh and the tenth. From this it is evident that the exposures were comparatively long, and consequently there would be considerable extension of the corona on the plates, which would obliterate the stars nearest the sun. The measures, however, were sufficiently exact to give a decisive result using the more distant stars. Profs. Campbell and Trumpler measured all their plates in duplicate; the values for the shift at the limb of the sun deduced from the individual plates ranged from 1·59″ to 1·86″, the mean of all being 1·74″, which is only 0·01″ less than Einstein's predicted value.

As Prof. Campbell is well known to have been in no sense predisposed in favour of Einstein's theory, this result, combined with that of Prof. Chant and the mean of the Principe and Sobral results in the 1919 eclipse, will probably be regarded as setting the question at rest. Prof. Campbell says in his telegram that he considers further work of this kind unnecessary, so that he will attack other problems in the Californian eclipse of next September. There are still the plates taken by the Australian expeditions to be measured. This is to be done at Greenwich; their scale is smaller than that of the Lick Observatory plates, so that probably less weight will attach to them.

The evidence as regards the presence of the shift in the solar spectral lines is now fairly evenly balanced "For" and "Against"; but in any case this test is a less decisive one than the other two, since there are so many known causes of shift of spectral lines, which it is not easy to eliminate completely.

A. C. D. C.

Current Topics and Events.

THE agricultural Tribunal of Investigation appointed by the Government to inquire into the present position of the farming industry and to suggest methods for its improvement has issued an interim report. Its recommendations are being actively discussed in the daily press, mainly from the political aspect. At present the majority of farmers are undoubtedly in an unsound economic condition, and especial interest therefore centres in these sections of the report dealing with agricultural organisation and education. The Tribunal is impressed by the extent of co-operative measures both in Europe and in America, and in urging that British farmers should form similar organisations, suggests that the study of the economic organisation of the industry should have fuller recognition in the farm institutes and agricultural colleges. The Tribunal pays a tribute to the work carried out by the research staffs of these institutions and considers that the departments dealing with the economic problem should be further developed. New systems of farm management, in particular the maintenance of livestock on arable land,—the soiling system,—are suggested as urgent problems to be investigated from this point of view. It is pointed out that in the United States 50 per cent. of the research grants are devoted to farm economics as against 10 per cent. in this country. In this connexion, however, it should be remembered that the term "farm economics" has a much wider interpretation in America than would be admitted here, due in part to the absence, until recently, of the settled rural population that marks the older countries. Making due allowance, however, for this and for the characteristic American tendency towards over-organisation, the comment of the Tribunal still remains true in substance. It is to be hoped that this essential bridge between the research workers and the farmers will be strengthened as a result of the Tribunal's recommendations.

THE Secretary of State for the Colonies has appointed an executive committee to control the researches recommended by the Inter-Departmental Committee on Research and Development in the Dependencies of the Falkland Islands, and in particular the investigation of the question of the preservation of whales and of the whaling industry, which has been subject to Government regulation since its inception nearly twenty years ago. The members of the committee are as follows:—Mr. Rowland Darnley (chairman), Colonial Office; Sir Sidney Harmer (vice-chairman), British Museum (Natural History); Mr. H. T. Allen, Colonial Office; Mr. J. O. Borley, Ministry of Agriculture and Fisheries; Capt. R. W. Glennie, R.N., Admiralty; Mr. J. M. Wordie, Royal Geographical Society; and Sir Fortescue Flannery, of Messrs. Flannery, Baggallay and Johnson, consulting naval architects to the Crown Agents for the Colonies, who has consented to serve as a member of the committee until the *Discovery*, which has been purchased for the purposes of the research expedition, has been reconditioned. In another part of this issue, Sir Sidney Harmer gives some account of the scientific results to be expected from the cruises which it is anticipated the *Discovery* will undertake.

THE report of the nineteenth year's work of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington has lately been issued in the Year Book of the Institution for 1922. The non-magnetic ship *Carnegie*, after twelve years' voyages which have been of great import to the science, is now out of commission for a time, while the observing staff is largely occupied with re-observations in land areas where further information, chiefly to determine the secular variation, was needed. An analysis of the vast body of data acquired by the Department is now in progress. Two magnetic observatories have been set up, in Western Australia and in Peru, regions of the globe where such institutions are much needed, and help has been given in carrying on the former German observatory at Apia, in Samoa. The Department has now turned its energies to the much-neglected study of earth-currents, and is devising new methods of registration. Dr. S. J. Barnett, chief of the section of experimental work in pure magnetism, is vigorously prosecuting his researches on magnetism by rotation, and the converse effect. The investigation of atmospheric electricity is also being extended. A conference of American men of science was held at the Department during the year, in order to consider what modifications, if any, of the original programme of the Department should now be made, and the conclusions and recommendations of the conference are being taken as a guide in the further development of the activities of the Department.

IN the "Shirley Institute Memoirs," vol. 1, 1922, recently received, are collected the ten papers published during the year by the British Cotton Industry Research Association. A perusal of this volume affords an encouraging picture of the future of textile research in this country if the high standard indicated is maintained. The work described falls naturally into three well-defined sections—chemical and physical, biological, and technological. Four papers are résumés of the literature of some chemical, physical, and botanical aspects of cotton, and should be of much value to workers in this field, in which the literature is scattered and much of it almost inaccessible: more than 380 references are given. The biological papers have been dealt with previously in these columns and need no further mention. The three most striking papers are the technological contributions dealing with some properties of yarns, such as regularity in relation to tensile strength and twist. They materially increase our somewhat scanty knowledge of the nature of yarns, and the original methods of investigation described are of wide application. Until the present publication little of permanent value has been done on yarn structure since the pioneer work of

Oliver in 1905–7 (Proc. Roy. Soc. Edin.). A large field of work of extreme difficulty and fascination is here awaiting attack by the physicist and the mathematician, and not the least important of the functions of textile research associations lies in removing such problems from the almost complete obscurity and isolation they have hitherto "enjoyed." It is almost unknown outside the industry that many of the most fundamental problems in textile technology are problems for the mathematician and the mathematical physicist, and there is little doubt that in a few years' time a real and considerable demand will exist in the textile industries for such workers: this should not be without interest for those engaged in the training of students in our universities.

THE Ministry of Agriculture and Fisheries has reissued Leaflet No. 71, dealing with the Colorado beetle. The discovery of this destructive insect in the neighbourhood of Bordeaux last year renders it necessary to take any precautions possible in order to guard against its entry into this country. On several occasions it has been carried by shipping to Europe, and has even become temporarily established on a small scale. During 1901–02 it occurred in potato plots in the neighbourhood of Tilbury docks, but was successfully eradicated by prompt measures. The present infestation in France is of a most serious nature, and it is known to have spread over about 100 square miles. In all probability its area of occupation is even larger, as it is difficult to investigate so large a district with equal thoroughness. The reappearance of the insect during the coming season will be watched with some anxiety, and, unless the most drastic measures are taken on a very large scale, there is every chance that it will remain, and ultimately establish itself as a continental pest. In the latter event it can be scarcely more than a matter of time before it reaches England, since it is obviously impossible to prevent stray insects coming over unobserved in vessels from Bordeaux. The potato in this country is singularly free from insect pests, and it is to be hoped that the Colorado beetle will be unable to establish a footing. It is, however, gratifying to know that the Ministry of Agriculture has given the matter the fullest consideration; but it is incumbent upon all growers to inform the Ministry of the first sign of the appearance of the insect in the field, in order that it can be dealt with immediately by experts. There is no doubt that it can be eradicated if measures are taken sufficiently early; but it is evident that in France it has spread and multiplied to an extent which renders effective control a matter of great difficulty.

IN the issue for March 9 of *Chemistry and Industry* appears a review of the position of the nitrogen industry in France. The French Chamber of Deputies has recently approved the agreement made in November, 1919, with the Badische Anilin und Soda Fabrik, whereby the French were to pay 5,000,000 francs for the right to work the Haber process, together with all information necessary to carry on the process as worked at Oppau and Merseburg. Part of this sum would be paid on the ratification of the agreement, and the remainder when the factory has produced a minimum of 20 tons of fixed nitrogen per day for fifteen consecutive days. A royalty would also be paid when production reached a certain figure. The agreement has given rise to much discussion of the merits of the Haber and other processes. An inquiry instituted by the French Government in 1921 led apparently to the conclusion that under existing conditions the Haber and Claude processes offered practically equal advantages, and the matter can be settled only on the basis of experience gained in working the various processes on a large scale over a considerable period. (Cf. NATURE, vol. 107, page 765; vol. 111, page 101.)

SEVERAL new flying records were established during February, according to the *Meteorological Magazine* for March. A record climb of 20,000 feet in 12 min. 24 sec. by Flight-Lieutenant Haig at Martlesham Heath is noted as announced in the *Times* of February 6. The speed at ground level was 189 miles per hour. At Marseilles, on February 15, M. Sadi Lecointe is said to have broken the world's record for speed over a four-kilometre course: his average speed was 234⅝ miles per hour, breaking the previous record by more than 10 miles per hour. Another French airman, M. Maneyrol, on February 26 established a record, making a motorless flight of 10 kilometres (horizontal distance) near Cherbourg during a strong south-westerly wind. Three notable flights are said to take place this year: an expedition of five French aeroplanes was to start on March 15 on a world tour, probably lasting two years. An American crew will fly from Berlin to Chicago, towards the end of the year, in the Zeppelin air-cruiser now being constructed for the American Government. A flight across the North Pole is to be attempted at the end of June in connexion with Amundsen's expedition; the distance to be covered is 2250 miles, and it is expected to fly this distance from Point Barrow to Spitsbergen in 26 hours.

WE are asked to announce that the Museum of Practical Geology, 28 Jermyn Street, S.W.1, is closed for repairs until further notice. The offices and library of the Geological Survey remain open.

THE Brussels correspondent of the *Times* states that it has been decided to begin Summer Time in Belgium on April 21.

ON Thursday next, April 26, at 3 o'clock, Prof. J. T. MacGregor-Morris will begin a course of three lectures at the Royal Institution on "Modern Electric Lamps," and on Saturday, April 28, Dr. Leonard Williams will deliver the first of two lectures on the "Physical and Physiological Foundations of Character." The Friday evening discourse on April 27 will be delivered by Prof. C. V. Boys on "Measurement of the Heating Value of Gas," and on May 4 by Prof. Soddy on the "Origins of the Conception of Isotopes."

AT a quarterly meeting of the council of the Royal College of Surgeons of England, held on April 12, the

Jacksonian Prize for the year 1922 on "The effects produced by radium upon living tissues, with special reference to its use in the treatment of malignant diseases," was awarded to Mr. H. Sidney Forsdike, of the Soho Hospital for Women. Sir Arthur Keith was elected Vicary lecturer for the ensuing year.

DR. H. H. DALE, head of the department of biochemistry and pharmacology of the Medical Research Council, the Rev. G. Milligan, Regius professor of divinity and Biblical criticism in the University of Glasgow, and the Very Rev. Dr. W. F. Norris, Dean of York, have been elected members of the Athenæum Club under the provisions of the rule of the club which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public service."

THE Institute of Physics admits physicists to a grade of associate membership, and it is believed that there must be a large number of young physicists at present outside the Institute who are eligible for this grade. All students and others who have conducted a year's work of satisfactory research are eligible if they have a degree of approved honours standing, or if they pass the equivalent examination of the Institute. Ultimately, it is probable that the associate group will be much larger than that of fellowship, and that new fellows will be selected mainly from it. The Institute has now an appointments register, and many applications for young physicists have been received from manufacturing firms and research laboratories. Regulations for admission to the Institute can be obtained from the secretary, Mr. F. S. Spiers, 10 Essex Street, Strand, London, W.C.2.

AT the meeting of the Royal Geographical Society held on April 9 the president announced that H.M. the King had been pleased to approve the award of the Royal Medals as follows: The Founder's Medal to Mr. Knud Rasmussen for his exploration and research in the Arctic regions during the last twenty-five years; the Patron's Medal to the Hon. Miles Staniforth Cater Smith for his explorations in the unknown interior of Papua. The council has awarded the Murchison Grant to Capt. A. G. Stigand for his map of Ngamiland; the Back Grant to Mr. B. Glanvill Corney for his studies in the historical geography of the Pacific; the Cuthbert Peek Grant to Messrs. R. A. Frazer and N. E. Odell to assist them in continuing their explorations of Spitsbergen; and the Gill Memorial to Capt. Augiéras for his journey in 1920–1921 from Algiers to Mauritania.

PRELIMINARY notice has been issued of the arrangements for the Hull congress of the Royal Sanitary Institute to be held on July 30–August 4. An inaugural address will be delivered by the Right Hon. F. R. Ferens on the first day of the meeting; on July 31, Sir Alexander Houston will lecture on "A Pure Water Supply," and a popular lecture on "Industry and National Welfare" will be given by Mr. B. Seebohm Rowntree on August 2. The congress will meet in four sections dealing with sanitary science, engineering and architecture, maternity and child welfare including school hygiene, and personal and domestic hygiene, respectively, and there will be numerous conferences of sanitary inspectors, health visitors, medical officers of health, veterinary inspectors and representatives of sanitary authorities. During the congress, a Health Exhibition will be held in the Wenlock Barracks.

THE annual report of the director of the Field Museum of Natural History, Chicago, for 1921, is written by D. C. Davies, who succeeded the late F. J. V. Skiff on December 19 of that year. The chief event chronicled is the re-opening of the museum in its new building (which is, we believe, in Grant Park) on May 2, 1921. The opportunity has been taken to place on exhibition for the first time a skull of the northern mammoth, found in gold-mining at a depth of 100 feet at Woodchopper Creek, Alaska. The specimen is represented on a Plate. Among accessions is to be noted the collection of Lower Palæozoic fossils made, chiefly from Ohio localities, by the late C. B. Dyer. The bird collection has been enriched by a large number of albinos and specimens of abnormal coloration. The removal of the museum has led to a large increase in the number of visits, especially by school children.

AT the Boston meeting of the American Association for the Advancement of Science in December last, the centenary of the birth of Gregor Mendel and Sir Francis Galton was celebrated by a series of addresses which are published in the March number of the *Scientific Monthly*. Prof. E. M. East dealt with "Mendel and his Contemporaries." Prof. T. H. Morgan, in a paper on "The Bearing of Mendelism on the Origin of Species," points out that small mutations are really the material on which Darwin chiefly relied to furnish a basis for evolution. He also discusses the question of species sterility, and points out difficulties of evolutionary interpretation which may arise from the occurrence of parallel mutations. Dr. J. Arthur Harris compares the influence of Mendel and Galton on the history of biology, and concludes that the latter has had a more varied and far-reaching effect on the history of science. Finally Prof. G. H. Shull asks for donations to a "Galton and Mendel Memorial Fund," the money to be applied to the publication of expensive illustrations in the journal *Genetics*.

WE have received from Messrs. Ridsdale and Co., of Middlesbrough, a report on the second period of three years in the preparation and use of a series of chemical standards prepared by this firm, with the voluntary co-operation of a number of analytical chemists throughout the country. The report was submitted to a meeting of the co-operators held recently at York. Very thin turnings of steel are now being used to facilitate the determination of carbon by combustion. The series of standards now available includes the whole range of carbon steels, together with four alloy steels, two cast irons, and a basic slag. Certain resolutions were passed at the meeting, urging the desirability of extending the use

of chemical standards for analysis, and the establishment of a more formal organisation on a firmer financial basis. These standards are now widely used, and the movement seems likely to become self-supporting, some 15 or 20 co-operators taking part in each standardisation, and the number of users, both at home and abroad, being large.

UNDER the title *Capita Zoologica*, a new quarto Dutch zoological periodical has recently appeared. It is issued under the editorship of Prof. Dr. E. D. van Oort, director of the State Museum of Natural History at Leyden, and is composed of transactions on systematic zoology, each part forming a complete work which is sold separately. A number of transactions will form a volume of about 500 pages, with plates and engravings. The contributions are published in English, French, and German. The part before us of this well-executed publication is Deel 1, Aflevering 4 (1922, price 24 guilders), and is devoted to a description of flies of the group Dolichopodinæ of the Indo-Australasian region by Th. Becker. It is evidently an important contribution by this recognised authority, and extends to nearly 250 pages, 222 illustrations occupying 19 plates. The previous three parts of this journal deal respectively with Nematodes, by Dr. J. G. de Man; Rhizostomes, by Dr. G. Stiasny; and Oligochætes, by Prof. W. Michaelsen.

WE have received from Messrs. Pastorelli and Rapkin, Ltd., of 46 Hatton Garden, E.C.1, a new catalogue of chemical thermometers. All the instruments listed are stated to be of British make, and as a guarantee of this the thermometers bear the name "BRITGLA," the registered trade mark of the British Lampblown Scientific Glassware Manufacturers Association, Ltd. The list in question is very comprehensive and covers a variety of ranges from −30° C. to 600° C. Thermometers with corresponding ranges on the Fahrenheit scale are listed in most cases. The ranges are varied in such a manner that it should be possible to select a reasonably open scale thermometer for any temperature. Quotations are given for two main classes of thermometers, namely, low-priced chemical thermometers and best quality standard laboratory thermometers. We are pleased to note that in both classes there is a considerable reduction in the prices which have been prevailing of late years. For convenience, the cost of supplying National Physical Laboratory certificates with the latter class of instruments is shown separately. A special section is also devoted to high range thermometers constructed of borosilicate glass and nitrogen-filled. These can be supplied in metal sheaths for industrial use.

PART 3 of volume 1 of the Abstract Bulletin of the Research Laboratory of the Lamp Works of the General Electric Co., Cleveland, Ohio, deals with 36 researches recently published, and extends to nearly 220 pages. It has been found advisable to expand the pure and applied sections of the laboratory into two separate laboratories for pure and applied science under the directions of Dr. E. F. Nichols and Mr. M. Luckiesh respectively. Both laboratories contribute to the researches abstracted in the present part. As an illustration of the thorough way in which industry in America is going into the scientific and technical questions which underlie manufacturing processes, we would direct attention to a paper of 32 pages by Mr. Luckiesh on the physical basis of colour technology, in which the methods used to investigate, by the help of the spectro-photometer, the properties of the dry pigments used in the paint industries, of the dyes, their mixtures and solutions, and of the various substances used in producing coloured glasses, are described. With data of the kind described available, many of the difficulties and obscurities of the colour industries are removed, and progress becomes rapid, while without them much groping in the dark is inevitable.

PART F of the "Guide-book of the Western United States" has just been issued as Bulletin 707 of the U.S. Geological Survey. Its author, Marius B. Campbell, writes for the tourist who looks with an intelligent interest from the windows of his parlour-car on the "Denver and Rio Grande Western Route"; but side-excursions are duly encouraged and described, and the maps show, in brown stippling, some ten miles depth of country on either side of the adventurous line. Numerous illustrations are given of the scenery along the route, which starts from Denver and ends at Salt Lake City. West of Canon City (not "Cañon" or "Canyon," be it observed) the railroad enters the Royal Gorge of the Arkansas River, which is cut 1000 ft. sheer in pre-Cambrian granite, overlain by stratified rocks of Upper Cretacous age. We are shown the fantastic arid weathering of the rose-red Permocarboniferous sandstone in the famous Garden of the Gods, and Pike's Peak appears as a portion of a snowy range. The ancient local glaciation of Colorado is not neglected, and the time-honoured error as to the origin of the term *roches moutonnées* is once more repeated on Plate 55. The protected fauna is illustrated, and the fauna that tried in vain to protect itself at the opening of Cainozoic times is finely represented by restorations of Stegosaurus and Triceratops. Stegosaurus, by the bye, means "roofed lizard," not "plated lizard." This and the other guide-books of the series must not be overlooked by those who travel in America, and they contain much geographical and geological information which is rendered accessible in European libraries, through the generosity of the Survey, for those who may never cross the Atlantic.

BULLETIN No. 133 of the Engineering Experiment Station of the University of Illinois is entitled "A Study of Explosions of Gaseous Mixtures," by Prof. A. P. Kratz and Mr. C. Z. Rosencrans. The report contains a valuable bibliography of the subject, beginning with Dalton and Humphry (not "Humphrey" as in the report) Davy, and after passing in review such classical researches as those of Dixon, Berthelot, Petavel, Bone, Jouguet (not "Jouget," as in the report), Thornton, and others, the literature references are carried up to 1921. A brief summary

of this work, and some new experiments by the authors are given. The report will prove useful to all who are interested in this very important subject.

MESSRS. DULAU AND CO., LTD., 34 Margaret Street, W.1, have just issued a valuable catalogue (No. 100) of upwards of 2600 second-hand science books and serials which they have for disposal. The list is conveniently arranged under the headings—ornithology, entomology, conchology, the lower invertebrates, general zoology, botany, horticulture, agriculture, geology, mineralogy, astronomy, mathematics, engineering, and early medical works. It should interest many readers of NATURE.

AMONG the books shortly to be published by the Oxford University Press is "The Glass Palace Chronicle of the Kings of Burma," which has been translated for the Burma Research Society by Pe Maung Tin and G. A. Luce. The chronicle is the work of the committee of "learned monks, learned brahmans, and learned ministers" appointed in 1829 for the purpose by King Bagyidaw of Burma. The title is taken from the Palace of Glass, in a chamber of which the compilation was made.

Our Astronomical Column.

GREECE ADOPTS THE GREGORIAN CALENDAR.—The Gregorian Calendar was adopted for civil purposes in Greece from the beginning of March. As Russia has apparently taken the same step, the old or Julian style becomes practically obsolete. M. D. Eginitis, director of the Athens Observatory, contributes a paper to the *Comptes rendus* of the Paris Academy of Sciences, March 12, in which he notes that the finding of the decree of Nicæa, A.D. 325, shows that, far from prohibiting such a change, it in reality rather demands it. The decree simply directed that Easter should everywhere be kept on the same day; by implication this day was the first Sunday after the 14th day of the first lunation after the spring equinox, which was assumed to occur on March 21. When it was found that the Julian Calendar did not maintain the equinox at this date, the reform at once became appropriate. The causes that for so long retarded its acceptance in eastern Europe were largely removed by the War, and M. Eginitis addressed a memorandum to the Greek Government in December 1918, which has now been followed.

The Greek Church is not at present adopting the reform, the reason being the expectation of the speedy adoption of other calendar changes in the west, for which it prefers to wait.

Some of these reforms are being discussed by the International Congress of Chambers of Commerce now meeting in Rome; but experience shows the extreme difficulty of persuading the world to adopt changes in their fixed habits, however desirable in themselves, so that we can scarcely share the sanguine view of M. Eginitis, who shares the expectations just mentioned.

THE EIGHTH SATELLITE OF JUPITER.—Prof. E. W. Brown contributes an article on this satellite to *Astronom. Journ.* No. 817. He makes use of Delaunay's algebraical expressions for the various terms, which are theoretically available for any satellite; however, in cases of such large eccentricity and inclination as those of J. VIII the terms do not converge rapidly enough to be used straight away. Prof. Brown, whose great experience gained in his new lunar theory comes useful, shows how estimates may be made of the remainders, and in particular finds a solution for the mean motion of the perijove. The general rule both with planets and satellites is that the apse moves in the same direction as the body, but in the case of J. VIII the higher terms of the series reverse the earlier ones, and produce motion in the opposite direction. Prof. Brown refers in his work to G. W. Hill's paper on the motion of the lunar perigee; it is interesting to recall that it was this work of Hill's that gave Brown the idea that he afterwards followed so successfully in his lunar theory.

The period of revolution of the perijove of J. VIII is about 800 years, an unusually long period for a satellite. It is welcome news that Prof. Brown proposes to continue his work till he has arrived at expressions which will enable the place of the satellite to be predicted without the tedious method of mechanical quadratures. Mr. J. Jackson has also been at work on the satellite, using a combination of observed and calculated positions, and gives an ephemeris for the present apparition in the *Observatory* for March. The chief importance of observing this satellite and the still fainter J. IX is that they will ultimately give a better value of Jupiter's mass than any other method.

ASTRONOMY IN THE UNITED STATES.—The section of Year Book, No. 21, of the Carnegie Institution of Washington, dealing with astronomical work carried out in departments of the Institution includes several items of general interest. The so-called K-term in radial velocities, that is, an average motion of recession shown by all spectral types, but especially by type B, where it amounts to 4 km./sec., is discussed. More than half of this is removed by adopting newly determined wave-lengths for the lines of oxygen, nitrogen, silicon and helium that were used; it is further pointed out that certain lines formerly used were double, and therefore unsuitable. A small residual recession may be due to the Einstein effect. Work on the proper motions of the red stars has shown that these are generally small in the case of types M and N; M stars have large radial velocities, they are therefore mainly giants, and very distant. The radial velocities of type N stars are small, indicating that their average mass is high. Both types give much the same direction for solar motion as that generally adopted.

Studies have also been made on the progressive differences of spectra from type Bo to B8. In B8 the oxygen and nitrogen lines disappear, while a number of enhanced metallic lines appear; it is anticipated that discussion of these facts may advance the theory of ionisation, and our knowledge of the constitution of matter.

The meridian observers seem to be worked very hard; they are on duty for a week at a time, and observe time-stars at intervals not exceeding 6 hours, besides circumpolars at both culminations. What would the advocates of an 8-hour day say to this? The object is to eliminate personality, but it is found that when an observer is fatigued he observes differently than he does when fresh. One of the objects of this series of observations is to determine the laws of differential refraction both in Right Ascension and Declination, and if possible to connect it with the meteorological conditions. There is little doubt that differential refraction is the cause of the perplexing variations in time-determinations from different observatories, and that its determination would mean a marked increase of accuracy in meridian work.

Research Items.

BONE HARPOONS DISCOVERED IN YORKSHIRE.—In 1922 Mr. A. Leslie Armstrong described in *Man* two bone harpoons said to have been found at Hornsea, West Yorkshire. At the Hull meeting of the British Association the harpoons were again exhibited, and Mr. Sheppard, curator of the Hull Museum, questioned their authenticity on various grounds. The matter having been brought to the notice of the Council of the Royal Anthropological Institute, a committee, consisting of Sir C. H. Read, Dr. A. Smith Woodward, and Prof. Percy F. Kendall, was appointed to investigate the matter. The report of the committee is published in the April issue of *Man*. The members report that there is no evidence in the objects themselves that is conclusively against their genuineness: that the similarity of the barbs in the two examples, though found 4 miles apart, points to the conclusion that they are the work of the same individual. "It is worthy of remark that at the time the earlier find was made there was no available example of a Maglemose harpoon." "Mr. Sheppard appears to have had strong grounds for doubting the authenticity of the harpoons, but the evidence on which his judgment is based is no longer verifiable."

BABY CLINIC STATISTICS.—No. X. of the "Studies in National Deterioration" (Cambridge University Press, 15*s*.), forming a subsection of the series of Drapers' Company Research Memoirs, is a thorough analysis of data provided by a baby-clinic in a large manufacturing town, carried out by Miss M. N. Karn and Prof. Karl Pearson. The authors have made very full use of the method of correlation and reach various conclusions of interest and practical importance. Two of these may be noted. The first is that there is a considerable if not very large (0·37–0·43) correlation between the health of an infant at birth and at the end of the first year, a result compatible with general biological considerations, incompatible with the catch word "all babies are born healthy." The second is that although the use of a baby "comforter" is associated with ill health over the full period of observation, the correlation is almost doubled when the health of babies under 14 days old is correlated with use of a comforter. The most plausible interpretation is that the delicate babies are preferentially supplied with comforters rather than that the comforter itself is an important cause of ill health. Those readers who are not versed in the correlational calculus will find the numerous diagrams helpful.

BOTANY IN INDIA.—The report for 1921–22 of Lieut.-Col. A. T. Gage, the director of the Botanical Survey of India, directs special attention to the appearance of Parts I. and II. of the "Botany of Bihar and Orissa," by Mr. H. H. Haines. These two parts contain the description of 76 families, from the Ranunculaceæ to Cornaceæ. Part IV. of the "Flora of the Presidency of Madras," by Mr. J. S. Gamble, has also appeared, containing the families Rubiaceæ to Ebenaceæ. The most interesting economic development in progress appears to be the promotion of cinchona planting in Southern Burma under the superintendence of Mr. P. T. Russell. Cinchona seedlings were planted out in May 1921, on a site near the Heinze river at an elevation of 1700 feet. Unfortunately this situation proved to be apparently "the point of impact of the very arrow head of the monsoon"; during June, July and August more than 240 inches of rain fell and more than half the seedlings succumbed. The survivors have since been growing very well, but it is proposed to recommence operations farther south in the Tenasserim Division of Burma, where the rainfall is both less in amount and more evenly distributed over the year. The cultivation of Ipecacuanha has apparently commenced very successfully on an experimental scale in Southern Burma, the temperature being more equable in this climate than in the Eastern Himalayas where this plant is grown.

GENETICS AND THE HISTORY OF WHEAT.—The Maine Agricultural Experiment Station continues to be prolific in genetic results, the chief contribution being from Drs. Karl Sax and John W. Gowen. In an important paper on sterility in wheat hybrids (*Genetics*, vol. 7, p. 513), Dr. Sax continues his work, in which it is shown that the three groups of wheat species, namely, the Einkorn, Emmer, and Vulgare groups, have respectively 7, 14, and 21 chromosomes as their haploid numbers. He has now investigated the chromosome behaviour in various hybrids between these different groups and finds conditions very similar to those obtained by Rosenberg, Gates, and others in similar hybrids. In crosses between members of the first two groups there are, for example, 7 bivalent and 7 single chromosomes, the latter separating at random when the former split. The origin of the tetraploid and hexaploid conditions in wheat is also discussed. Prof. Percival has shown that all three of the groups of wheat can be traced back to prehistoric times, Einkorn being grown in Central Europe in Neolithic times, Emmer and Vulgare also being prehistoric in Europe, and the former dating back to 5400 B.C. in Egypt. All the groups are therefore of sufficient age for a considerable evolution to have taken place within them. The higher numbers of chromosomes appear to have arisen by duplication of the original set of 7 pairs. This would mean also duplicating the hereditary factors present. Now in wheat, 14 different characters are known to be dependent on one factor, 4 depend on two factors, while only the red grain colour is represented by three independent factors. Hence it would appear that in the polyploid wheats most of these factors had arisen as mutations after the origin of the tetraploid and hexaploid conditions. Prof. Percival considers that the Vulgare (hexaploid) group arose as a hybrid between *Triticum aegilops* and a member of the Emmer (tetraploid) group. The study of the chromosomes is clearly of the greatest importance in tracing the history of our cultivated crops. The species of Avena (oats) show a similar series of chromosome numbers. Polyploid wheat hybrids produce small or wrinkled seeds. The endosperm in a cross between tetraploid and hexaploid forms may contain $14\times2+21(=49)$ chromosomes or $21\times2+14(=56)$ chromosomes according to which is the male parent, as the female parent contributes two nuclei. These unbalanced conditions result in abnormal development of endosperm.

INFECTION AND CYTOLOGICAL STUDIES OF PLASMOPARA.—In the Journal of the College of Agriculture, Hokkaido University, Sapporo, Japan, Vol. XI., Part 3, Makoto Nishimura gives a description of the methods of infection and of fertilisation of *Plasmopara Halstedii* Farlow, parasitic upon *Helianthus annuus* and other Composites in America. Although published in Japan this work was carried out at Columbia University under the guidance of Prof. R. A. Harper. The most striking feature of the infection experiments is the demonstration of zoospore infection through the roots, the zoospores apparently penetrating the middle lamellæ in the absorptive region of the root.

Oospores were freely formed by the fungus, especially in the roots of the host, but also in stem and leaf, and fertilisation was studied in properly fixed and microtomed material. An interesting description is given of a large " receptive pupilla " of the oosphere which protrudes into the antheridial cell at first, in a manner that recalls Murphy's description of fertilisation in *Pythium erythroseptica*. Afterwards this protrusion is withdrawn and apparently its retraction conducts the fertilisation tube from the antheridium into the centre of the oosphere. One nucleus is discharged through this tube into the oosphere from the antheridium.

UNITED STATES GEODETIC SURVEY.—The annual report of the United States Coast and Geodetic Survey for 1922 contains a long record of work accomplished during the year. Hydrographic surveys were carried out principally in the approaches to Chesapeake Bay, off northern California, in the waters of south-east Alaska, and the Philippine Islands. New charts, to the number of 27, were published to cover all areas for which adequate data were available. In some areas, principally Alaskan waters, the production of new charts is delayed until the primary triangulation is completed. The aerial survey of the Mississippi delta was finished and promises such favourable results that an extension of this means of coastal survey is projected. Outstanding features of the geodetic work of the Survey were the completion of the 1600-mile arc from Huntsville in Alabama to Williams in Arizona by way of Memphis and Albuquerque. This arc furnishes accurate positions in seven states and crosses an area badly in need of horizontal control. Work was continued on several other arcs, including one from Dixon Entrance to White Pass, Alaska, which is part of a long arc from Puget Sound, in which the Canadian Geodetic Survey is co-operating. Good progress was made in precise triangulation in Alaska. The Survey is co-operating with a committee of scientific workers in making an intensive study of earthquake phenomena. Magnetic work and tidal observations were extended during the year. The director points out the need for investigations on the Atlantic coast and particularly for the exploration of the Gulf Stream. He urges also that oceanographical work should be undertaken in the Atlantic outside the 100-fathom line and in the Pacific beyond the 1000-fathom contour. Lastly, he emphasises the amount of wire-drag work that must be done along the coasts in the interests of navigation.

THE CRUMPLING AND RIFTING OF EARTH-BLOCKS.—Otto Baschin, of Berlin, in *Die Naturwissenschaften* for February 9, directs attention to what he believes to be a hitherto unnoticed factor in the tectonics of the earth's crust. He starts by the admission of considerable vertical movements of elevation and subsidence in the crust, and these are probably of an order that Wegener's hypothesis rejects. Baschin urges that a rising earth-block, as it comes into a region with greater rotational velocity than that in which it previously lay, becomes a retarding influence in its new surroundings, and in consequence exerts a pressure towards the west. Similarly, a sinking block is an accelerating factor and exerts a pressure to the east. If a continental block sinks on the east side of a line running north and south, and rises on the west, rifting may occur along the line ; if it rises on the east and sinks on the west, compression and axial folding are set up. Other cases are of course considered, and the drifting of blocks towards the equator (*Polflucht*) is discussed.

THE LARAMIE PROBLEM OF THE ROCKY MOUNTAIN.—The coal-bearing beds of the Rocky Mountain region have now been the subject of a considerable literature, and in Professional Paper 130 of the U.S. Geological Survey (Washington 1922), F. H. Knowlton presents a useful review of the progress of what is known as the " Laramie problem." In 1875 this problem led Cope to the conclusion that there was no alternative but to assume the possibility " that a Tertiary flora was contemporaneous with a Cretaceous fauna, establishing an uninterrupted succession of life across what is generally regarded as one of the greatest breaks in geologic time." The term Laramie itself arose out of the need for a non-committal term for beds regarded by Clarence King, then at work upon the exploration of the fortieth Parallel, and by F. V. Hayden, busy with the survey of Northern Colorado, as certainly conformable, although it was regarded by King as Tertiary and by Hayden as Cretaceous. Knowlton, having shown that the work of Lee and himself makes clear the existence of an unconformity in the midst of the coal-bearing so-called Laramie rocks of Colorado and New Mexico, points out that when their flora is studied in detail the strata below the unconformity are Cretaceous, and those above Eocene. This work, based upon a long study of all the main collections of plants from these strata, has been in progress since 1889, its publication being delayed until its author was clear that the long-standing problem was definitely in process of settlement. The flora so carefully studied is not in itself extensive, and the preservation of the plant impressions in the soft friable sandstone is far from perfect. The specimens are very fully described, and are figured in 28 plates, some pen drawings, and photographs.
